It is said that the honorarium given a professor was so small he could barely exist upon it; Jacques Bogaert, who became professor in the university May 24, 1480, received an honorarium of 50 florins. On account of his zeal and talents, the civic authorities granted an extra honorarium to Jan Spierink (Spiringus), a canonic professor in the university and first physician to Philip, Duke of Brabant and Burgundy. He founded the medical library at Louvain, which was almost entirely destroyed by the soldiers of the Duke of Alva in 1578. Molanus says that the skill of this man saved the life of Adrien Boeyens, afterwards the Pope, Adrien VI.[2] On June 7, 1557, Guillaume Bernaerts was made professor and received a salary of 100 florins. Although there were many physicians of merit in the Netherlands at this time, they would not accept positions in the university on account of the small salaries offered them.[3] Rembert Dodoens, born at Malines, June 29, 1517, a graduate of the University of Louvain, one of the first physicians of his time, called the father of botany and horticulture in Belgium, a pioneer in pathological anatomy and physician to Emperor Maximilian II and Rudolph II, and appointed professor of medicine at the University of Leyden in 1582, refused the prior offer of the chair of medicine at the University of Louvain on account of the parsimony of the authorities of the university, and because of the rules governing a member of the faculty which interfered with that member's practice to such an extent as to make the practice of medicine outside of the university practically impossible. The authorities of the University of Louvain began by offering Dodoens 150 florins, raised it to 200, then 250. Dodoens demanded 300 florins in gold for his services. In 1558 Philip II created a new professorship, the duty of the incumbent who was appointed either by the civic authorities or the sovereign being to construe the Ars Parva Galeni. This chair was held successfully by three men, when

in 1577 it was abolished because of lack of funds.[3]

At this time there were two official professors, two canonic professors (or professors of the second foundation), and one professor extraordinary or royal professor (the chair being founded by Philip II). The salary of the royal professor was 100 florins until February 10, 1601, when it was raised to 140 florins.[3]

In 1624 a professorship was made by the States of Brabant with a salary of 200 florins. Adrien Rhodius was the first and last doctor of medicine to hold this position.[12]

Jean Wautier van Vieringen (Viringus), born at Louvain in 1539, one of the most celebrated professors at Louvain, became professor of medicine in 1571, and during his professorship the pest devastated Belgium (1574-1580), and almost 50,000 of the inhabitants of Louvain died of the disease during this period. Gemma, Varentius, Thibaut and Bruegelius, in fact all of the members of the medical faculty, excepting Viringus, succumbed to the plague.[2, 13] New professors were appointed and much discord arose in the faculty, due to the Duke of Parma, governor of the Spanish Netherlands, claiming the right to appoint Pierre Smenga to succeed Gemma. The authorities of Louvain maintained that the Duke had no right to make this appointment and they appointed Pierre Ricard to the chair. The two professors gave their courses in opposition to each other, and Viringus, the senior professor of the faculty, had no little trouble in keeping peace among the members. In 1593, after being ordained a priest, Viringus left the university, to the great regret of his colleagues and students.[7]

Before 1577 there was no special college of medicine in the University of Louvain. A professor in the medical faculty, Pierre Bruegelius, founded a medical college with part of his professional fees. "Qui perpetuam sui memoriam reliquit," says Molanus, "fundans ex honorariis laborum et studiorum suorum Collegium Medicorum."[2, 9]

On the occasion of the nomination of Professor Gérard de Villers in 1593 a lawsuit arose between the magistrate of Louvain and the government of the country, which lasted until December 14, 1599, when the supreme council of Brabant decided that before the magistrate appointed a professor he must inform the government or its representative, the governor general. This was the first time that the government interfered with an appointment to a place in the medical faculty, the making of which was vested in the civic authorities.[2, 7]

Once, in the absence of the chancellor of the university, the dean of Saint Pierre, on the insistence of the faculty of medicine, conferred the degree of doctor in medicine upon one Jean Franco of Eersel. The university, on learning of this infraction of its statutes, resolved that any faculty of the university which permitted itself to so forget the rules of the university would be liable to a fine of 300 florins, and that the title so given to anyone would be considered valueless.[12]

The University of Louvain suffered severely from the 43 years of war which was waged in Belgium. The disturbance of the political equilibrium disorganized the university. No endowments or foundations were made and the scientific and pecuniary interests of the professors suffered. Pope Gregory XIII, however, on learning that there were no funds to pay the salaries of professors, sent, on August 6, 1580, 2000 ecus in gold to be distributed among them.[12] It became necessary to strengthen and build up the university. Peace was declared in 1609, but as early as 1606 two commissioners were appointed to visit and investigate the university. The members of this investigation committee were Jean Drusius, Abbé du Parc, representing the ecclesiastics, and appointed by the papal nuncio on June 7, 1606, and Etienne van Craesbeke, advisor of Brabant representing the government and appointed by the Archdukes Albert and Isabella, who were the representatives of Philip II in the Spanish Netherlands.[2]

The great expenditures required to obtain the degree of doctor of medicine dismayed many aspirants, and both students and professors desired less ceremonial on conferring this degree because of the expense incurred. In 1614 the students petitioned the Archdukes Albert and Isabella as follows: (1) To have the University of Louvain follow the example of the universities of France and Italy and confer the degree of doctor only upon those who had passed a rigorous public examination. (2) To exempt the students from the great expense occasioned by the dinners and other ceremonies which were customary on receiving their degree of doctor of medicine. (3) To permit to the practice of medicine only those who had graduated from the University of Louvain.[2] This petition of the students very likely had some influence upon the action of the committee which was appointed in 1606. The result of the committee's investigation was known as "the act of investigation, and was made public in 1617 at a reunion "of all the members of the university." Under this so-called "act of investigation of the Archdukes Albert and Isabella" the University of Louvain was thenceforward directed by the state. The "act" was the new charter of the university, in which was specified the jurisdiction of the university authorities, the privileges of the corporation, the pedagogical interests, the interests of the colleges, the rights and duties of the professors in all the faculties, and the conduct and discipline of the students and functionaries. It was stated in the preamble of this act that all these dispositions had been taken in concert with the Holy See: "Juncta in primis sedis Apostolicæ authoritate."[2, 4]

The "act of investigation" established four chairs instead of two. Two of the professors in these chairs were appointed by the magistrate of Louvain and were called "Primarii," the other two were appointed by the government and were called "professors royal or Regii." Besides the so-called "official teaching" the act permitted "free teaching" by the doctors associated with the university. Each day's teaching was divided among the professors as follows: (1) The duty of the first professor was to explain "the institutions of medicine taken from the first canon of Avicenna," from 3 to 4 P. M., and in summer from 4 to 5 P. M. (2) The second professor had charge of a course in the theory of medicine, embracing the Ars Parva of Galen, the aphorisms of Hippocrates, and the general methods of practice. He lectured also upon purgation, bleeding, the pulse, and urine. His course was to be given from 10 to 11 A. M. (3) The third professor was to give a course in the practice of medicine, daily from 8 to 9 A. M.; "to teach all the diseases that might occur in the body from the head to the feet, according to the writings of the Arabian physician Rhazes." (4) The fourth professor was to give a course in anatomy every day from 2 to 3 o'clock and to give anatomical demonstrations upon cadavers whenever he could obtain them. In summer he was

to teach surgery and "everything medical pertaining to the art of surgery." The course of medicine was to be three instead of four years.[1] These new statutes had a great influence upon medical teaching in Belgium, increasing the prestige of the medical faculty at Louvain and attracting a larger number of medical students there.

The most famous Belgian in medicine during this century was Henri Joseph Rega, born April 26, 1690, who, appointed professor when 22 years old, was instrumental in building the amphitheater for anatomy and founding the botanical gardens at Louvain.[2]

"The first half of the eighteenth century as well as a large part of the seventeenth fill sad pages in the history of Belgium. The increasing weakness of Spain, the increasing power of the United Netherlands, the war of the Succession, the occupation of the country by Louis XIV and Louis XV and other political conditions weakened or condemned to inaction all the vital forces of the nation. But in spite of the numerous obstacles arresting its development the university continued to fulfil its honcrable mission."[4]

By the treaty of Aix la Chapelle, October 18, 1748, the Empress Maria Theresa of Austria became ruler of Belgium. Under Austria's rule the teaching of medicine did not advance at Louvain, although the Empress attempted to raise the standard there because the new laws were made by strangers, Cobenzl and Kaunitz, who treated Belgium as if liberty had never existed there and because these laws emanated from a single source, which rarely consulted the interests of the professors or the civic authorities of Louvain, Broeckx, in commenting upon the failure of the reforms made in medical teaching at Louvain, says: "They could have accomplished these reforms easily if they had instituted, as things are done in our days (1865), a committee composed of one professor in each faculty, directed by an agent of the government, this committee to give account annually of the standard of teaching, the subjects taught, and the improvements which could be introduced. Then they would not have hurt the patriotic feelings of the professors, by appointing strangers who were sold body and soul to the courtiers whose rule was absolute."[2] But with all her reforms the Empress did not succeed in reducing the student's expense in obtaining his doctor's degree, as both faculty and students had desired for a long time. The cost at this time of obtaining the degree of theology was 1,220 florins 11 sous (Brabant) of the doctor in laws 1,777 florins 19 sous (Brabant), and of doctor of medicine 1,738 florins 11 sous (Brabant).[3]

In 1780, the medical faculty consisted of two primary professors, four professors royal, and two professors in ordinary. The teaching was so divided that the two primary professors and the two professors in ordinary taught pathology and therapeutics and the professors royal taught botany, chemistry, anatomy, and "the fundamental principles of healing."[5]

Joseph II succeeded his mother as Emperor of Austria and ruler of Belgium. This Emperor, whom Faidherbe calls the "Philosophic Emperor," and Broeckx the "Regulator par Excellence" through his enterprises, almost closed the doors of the University of Louvain. Inspired by the ideas of a theorist who would make general reforms, and instigated by Count von Trautmansdorf, Joseph II undertook to turn the University of Louvain upside down. From the first he encountered desperate resistance: the greater number of the professors and almost all of the students opposing his unjust and dangerous projects.

In this conflict in the university, the faculty of medicine was divided into two factions; one made up of Jacquelart, van Bochaute, and Willem van Leempoel, agreed with the Emperor's ideas, while the other faction, consisting of van der Belen, van Gobbelschroy, van Rossum, Vornuck, and Michaux, stood for the rights and privileges of their Alma Mater. Irritated by this opposition, Joseph sent to Austria for professors for the medical faculty, and in 1786 installed one Melly as dean of this faculty without, however, succeeding in crushing the opponents of his projects. The fight continued, and on February 29, 1788, he removed Clavers, the rector of the university, and put in his place Professor van Leempoel, a member of the medical faculty, who had taken sides with his majesty. Furious at this new alleged outrage and menaced by Austrian and Hungarian troops, the greater part of the students studying medicine and theology at Louvain, left the university to obtain their education elsewhere.[14]

In Joseph II's decree, September 30, 1788, the following subjects were ordered to be taught by the faculty of medicine: (1) Special Natural History, (2) Botany, (3) Chemistry, (4) Surgery, Theory, and Practice, (5) Obstetrics, (6) Anatomical Demonstrations upon the Cadaver, (7) Physiology and Experimental Physiology, (8) Materia Medica and the Methods of Prescribing, (9) Pathology, (10) Clinical Medicine.[2]

By a decree of July 17, 1789, Joseph II transferred the faculties of law, medicine, and philosophy from Louvain to Brussels, where he founded the "College Thérésien." He had hoped by breaking traditions to lead the students to an institution which was governed by his reformatory ideas. But he did not succeed.[5]

In 1790 the medical department was reinstated at Louvain. Then followed the French revolution, which was fatal to the university. The following is a translation of a decree of the Administration of the Department of the Dyle, October 25, 1797:

Equality—Liberty—Fraternity.

Brussels the 4th Brumaire, 6th year of the Republic.
The Central Administration of the Department of the Dyle to the Municipal Administration of Louvain.

Citizens,

The Minister of the Interior having ordered us, we decree that teaching cease at the University of Louvain. The Citizens Vauthier and de la Serna, who will present this decree to you, are charged by us not only to direct the operations relative to this important measure, but also to insure a proper guardianship for the mobile and immobile property of this establishment. With full confidence in your patriotism and devotedness, we hope you will concur in every way possible in the prompt and complete execution of our decree,

Greetings and Fraternity.

The Administration of the Department of the Dyle. Signed, President Le Hardy, Faubert, Fourmaux, J. de Bériot, F. E. Bataille, Mallarmé, Dellecroix.[2]

Notwithstanding the wars which devasted Belgium and the ruins produced, the great prosperity of the University of Louvain had continued for three and a half centuries without interruption, "because

at Louvain professors of the highest merit were found who, animated by the love of country and science, concurred with the authorities to attain a goal, the advancement of science and the exaltation of the honor and dignity of their university." The motto of Belgium is, "L'Union fait la Force"—"Eendracht maakt Macht."

A CASE OF THROMBO-ANGIITIS, WHOSE WASSERMANN WAS FOR A LONG TIME NEGATIVE, BUT IS NOW POSITIVE.

By WILLIAM C. LUSK, M.D.,

NEW YORK.

This case of thrombo-angiitis was shown by me on April 23, 1913, before the New York Surgical Society (*Annals of Surgery*, Nov., 1913, p. 671), as one whose symptoms had been relieved and whose function was becoming restored in conjunction with the use of the Schnee four-cell electric bath. The now important features in this case are, first, that with a history of luetic infection in 1895, his Wassermann taken six times (once of the spinal fluid) in the year 1913, was always negative or doubtful (five of the tests were made by Dr. John A. Fordyce), and that recently, a year later, two examinations of the blood, one made by the Health Board and the other by Dr. John A. Fordyce in his private laboratory, have both been strongly positive; second, the influence on the symptoms of the treatment, (a) that by the use of the Schnee four-cell electric bath, and (b) that by the use of the antispecific remedies.

Male, age 36, moderate smoker. Onset of the disease 1901. For the previous nine years he had operated a heavy sewing machine with his feet. The first symptom was a cramp in the left calf coming on during walking. In 1904 left foot amputated (Pirigoff) by Dr. Jos. D. Bryant, with complete relief of the pain. The patient later used an artificial leg. From 1905 to 1910 he operated the same heavy sewing machine, using his right foot. His right calf then began to cramp and the usual symptoms of pain followed. In the fall of 1912 the patient, then in St. Vincent's Hospital, was suffering from terrific burning and worse, freezing pain in the remaining foot. In an effort of despair recourse was had to the Schnee four-cell electric bath, and it was found that this treatment, unless the current was too strong (best strength 10 ma. for 10 minutes) would always either arrest completely or ease the pain for a number of hours. With the use of the electric bath daily, beginning Nov. 10, 1912, the pain finally got under practical control and the patient began to use his foot with comfort (April, 1913). Accompanying the use of the electric bath the toenails, after a period of indolent growth, began to grow normally again, and some hairs sprouted on the dorsum of the foot. Thus the bath had apparently exerted a favorable influence on the nutrition of the foot. The baths were continued with a few short interruptions until Aug. 12, 1913. In the late spring and summer of 1913, the patient regained considerable activity, walking comfortably from one-half to three-quarters of a mile. For 7 or 8 weeks previous to stopping the baths, with the exception of three or four days around the end of July, there was practically no pain. Soon after stopping the baths there began to be a little recurrence of the pain again. In the meantime a sinus in the little toe had grown more extensive, communicating with bone.

The antispecific treatment the patient had had up to this time in the course of his illness, had been with iodide of potassium and mercury only, given irregularly, which seemed never to have given him any relief. During the taking of the electric baths the patient was given mixed treatment only for one week in March and then not again until July. In testing for the Wassermann reaction, Dr. Fordyce, who kindly contributed the facilities of his private laboratory to aid my investigations, suggested the giving of a six weeks' course of mixed treatment to be followed by a provocative dose of salvarsan, which therapeusis was carried out. The first dose of Ehrlich's remedy, neosalvarsan 0,45, was given Aug. 16, 1913. A Wassermann taken a week later was negative, as well as another taken nine days following the second dose of salvarsan, which was given on Sept. 5. A Wassermann was next taken a year later, on Aug. 25, 1914, when it was found to be strongly positive, and again on Sept. 14, when it also gave a strongly positive reaction.

The effect on the patient of the second dose of salvarsan (0,2 of the old), given on Sept. 5, 1913, was quite remarkable. Within the next ten days following its administration the sinus in the little toe entirely healed up, and has remained healed, up to the present time (Oct., 1914). The foot became warmer, the patient's activity increased, and he became possessed of a sense of well-being not before entertained. Following a third dose of salvarsan (old, 0,2) the slight remaining irritation in the little toe entirely left, and the patient went home from the hospital.

This experience seemed to demonstrate that a proper use of the antispecific remedies was what this patient needed. The antispecific treatment administered since beginning the electric baths on Nov. 10, 1912, has been as follows:

March, 1913 ..... Mixed treatment (one week)
July and first half of August, 1913..Mixed treatment
August 16, 1913.....Neosalvarsan 0.45
Sept. 5, 1913.....Salvarsan (old) 0.2
Sept. 17 .....Salvarsan (old) 0.2
Sept. 26 .....Old Salvarsan 0.25
Dec. 19 .....Neosalvarsan 0.45
Jan. 16, 1914.....Neosalvarsan 0.45
Aug. 25 .....Neosalvarsan 0.45
Sept. 14 .....Neosalvarsan 0.45
Sept. 28 .....Neosalvarsan 0.45
Between Sept. 20, 1913, and March 27, 1914, he received 13 injections of salycilate of mercury, ¾ to 1 grain each. Also three mercurial injections of 1 grain each have been given since Sept. 20, 1914. For five weeks during July and August, 1914, he took one or two doses of mixed treatment per day, preparatory to getting salvarsan.

The recourse to salvarsan in December, 1913, and August, 1914, was made because of recurring symptoms. In December, 1913, he had a slight cramp in the front of the right leg above the ankle when the foot was at rest and dependent, and a "drawing" of the little toe, neither of which symptoms seriously bothered him. He could easily walk 15 blocks, and could have walked further except for the discomfort of his artificial limb. Two days after taking the neosalvarsan 0,45 on Dec. 17, 1913, these slight symptoms entirely disappeared.

From December, 1913, to June, 1914, his right leg felt normal and served him usefully. Early in June of the present year the right calf and back of thigh began to cramp or pull, and there was a drawing sensation across the front of the right ankle when he walked. In walking about ⅛ mile he had to stop five or six times because of the cramps. The nutrition of the right foot, however, has remained good, and there has been no recurrence of the pain in it. The cramps were not benefited by the five weeks' course of mixed treatment last summer, given preparatory to salvarsan.

Early last August, at a time when he was taking the mixed treatment, there was a recurrence of the disease in the stump of the left lower extremity. An ulcer about 1¼ inches long with bluish edges developed on the front of the stump and associated with it were the torturing, burning, and freezing pains. There had been no direct pressure of the artificial leg on the stump at the site of the ulcer. Also in this extremity there had been cramps in the thigh for a number of days in January, 1914, and in February incident to taking a long walk, using his artificial leg, he had had cramps in the calf.

Now, on the 25th of last August, with the patient's right lower extremity affected with cramps on walking, and the stump of his left lower extremity the seat of ulceration and excruciating pain, salvarsan dosage was begun again, followed by injections of mercury. Two or three days after the first dose of this last series of salvarsan, the cramps in the right lower extremity ceased entirely, at least for walking short distances (1 to 1½ blocks), which was all the patient was able to do on account of his difficulty in using his now painful left leg. The right lower extremity has, since then, again felt normal. As regards the present status of the acute condition in the left lower extremity, as possibly influenced by the salvarsan and mercury recently administered, it can but be stated that the pain is now less, but that five days ago the patient had an attack of very severe cramps in this leg and thigh while endeavoring to walk (using artificial leg) a few steps, which practically held him bound. (Later note, October 12, 1914: For a week following October 2, the pain was again severe, and then lessened.) Thus the present painful condition cannot as yet be regarded as having received positive benefit from the recent antispecific treatment, but it would nevertheless seem indicated in this case, with the Wassermann now established as positive, that the antispecific therapeusis should be pushed.

As a result of a somewhat limited experience with the treatment of tertiary syphilis in cases of thoracic aneurysm, I am very much impressed with the seemingly marked beneficial results of giving salvarsan, when this drug has been preceded by a long course of potassium iodide and mercury. The giving of salvarsan alone in repeated doses to cases of aneurysm has seemed to be followed by an increase in the severity of the symptoms. Lesser, of Berlin (*Berliner klin. Wochenschrift*, March 16, 1914, p. 494), states regarding the treatment of late tertiary lesions of syphilis, that "especially in the diseased conditions of the internal organs one should be warned against beginning at once with salvarsan, since a resulting active reaction can be attended with considerable danger. Preliminary treatment with mercury and iodide should therefore always precede the first dose of salvarsan."

THE NECESSITY FOR BROADER CONCEPTIONS IN GASTROENTEROLOGY.

By CHARLES SUMNER FISCHER, M.D., PH.D.,

NEW YORK.

It is a refreshing thought and encouraging sign that the gross mechanistic attitude toward digestive diseases, exhibited during the past decade, gives evidence of having reached its limit, and that it is beginning to be realized that behind and beyond the strictly organic features of these disturbances there may lie causative factors not directly connected with the alimentary tract—factors which determine and shape such disturbances, and which are apt to be obscured by the magnitude of the lesions for which they are responsible. The long accepted connection between chemicophysical insult and organic stomach diseases has become so petrified in lay and professional thought that the demand is made in advance for diagnoses that will satisfy these conditions. As a result of this tendency there has developed a revelry and debauch of ingenious mechanical and complicated physical procedure to determine certain concrete results of processes which at best are rarities compared to the great mass of our digestive troubles. Because certain surgical clinics upon which the material of a State or country is concentrated, can produce statistics of the frequency of such affections as duodenal ulcer, it is not at all demonstrated that the conditions are frequent when considered in comparison with the general nature of the cases encountered in office or clinic. Such statistics have oftentimes been misleading, and have done a positive harm, for they have aroused in the lay mind an unwarranted anxiety as to the possible outcome of the ordinary and common cases. This doubt, thus engendered, is occasionally so pernicious and so difficult to dispel, that it constitutes a certain argument for inadvisable surgical procedure. In other words, the end is supposed to justify the means. This constitutes a moral question, and must be decided by the moralists. It can be however remarked in passing that for those who have their ears to the ground and are willing to hear, there are certain vague echoings coming from the ranks of the general profession which would seem to indicate that all is not right in gastrology and that, if these tendencies

are not controlled or modified, there may result a certain disrepute.

It must be evident that the simple physico-chemical conception of gastric diseases is a limited one, and can be applied to but one phase of the subject, namely, to final results. This appears to be the tendency of the gastrological procedure of the day, whereas the whole spirit of modern medicine is one of prevention, to attack diseases at their source. This spirit is lacking in the average gastric clinic. Here every effort is made to determine the actual local conditions and the proficiency of the clinic is judged by the finesse of the operations employed. Very little attention is given to the broader aspects of the cases, involving as they do, a thorough investigation of the relations existing between the organic changes and the various sociological, neurological, and constitutional forces, at work perhaps for years, productive of those changes, for the great majority of our digestive diseases; those chronic conditions affecting the contentment and working capacity of the individual, are the result of causes which can never be ascertained by mechanical means. They lie far deeper than such measures can reach, and if gastrological science wishes to be far reaching in its usefulness, it must attack the problem from another quarter. A very respected authority recently made the remark that every successful gastrologist in the future would perforce have to be a surgeon, at least, a manipulator—which is tantamount to saying that the best method to correct an abnormality affecting a human primitive instinct, would be to amputate the instinct.

The secret of this whole situation in practical gastrology, lies in the bare fact that it is much simpler, requires less time, energy and knowledge, to analyze and manipulate than it does to investigate the real physiological, pathological, neurological, sociological, and psychological factors determining the production of the average run of cases. The work of the past has demonstrated that the great majority of the gastric diseases develop along pretty well defined lines, are permissible of fairly accurate grouping, and that the various final structural changes, attracting a momentary superabundance of attention, are but the results of certain universal tendencies prevalent in modern life. In most cases, very marked final changes are never reached, the processes stop midway, but from a simple occasional hyperchlorhydria to a fully developed hypersecretion with pyloric spasm and obstruction, from gastric hypermotility to possible duodenal ulcer, constitutes a slowly progressive development, the various stages of which have been construed into distinct entities, separate and apart from the underlying principles governing them all. As we are rapidly being emancipated from the hydrochloric acid idea in stomach diseases, so we are going to pass beyond these momentary fads and fancies to view these successive phases in the light of a critical survey of the whole subject. It will be the care of the comprehending gastrologist of the future to determine, if possible, the tendencies in each individual case, so that gross structural final changes shall never be attained.

It has been very noticeable during the development of the whole hydrochloric acid situation in the past that whatever may have been the nicety of distinction of this or that phase, emphasized into clinical entity by the enthusiastic conception of the individual investigator, that one and all, when it came to the question of causation, have been driven to the assumption that somewhere and somehow the primary results came from conditions affecting the organs indirectly. It has been tacitly recognized that whatever may have been the ingenuity of local treatment and manipulation, this could not be effective unless the general conditions were favorable, that oftentimes the local measures were beneficial only in so far as they exerted an influence beyond the local conditions. It is becoming more and more evident that a good proportion of our prevailing digestive troubles are not such in the strictest sense, that they, in the beginning at least, are but local manifestations of general conditions, and that the organs involved can best be served by no treatment whatever. "Truth is truth when it works." Nowhere is this happy pragmatism more apt than in its bearing upon some of the more recent gastrological manipulations, for there cannot be much of general value to procedures which require such a special setting as to be beyond the means of those who need them most, who are not blessed with abundant leisure and a well padded purse. Even where the latter are available, the difficulties of application are so great, their successful manipulation so problematical, the beneficial results obtained so fleeting, that in all probability their employment will in due course, as heretofore, become a matter of history. In this connection it would be well at times to remember the advice of Czerny, that no specialized procedure should be given to the public or the profession generally until it had been thoroughly tested for at least five years in hospital and clinic. Such conservatism is however not in harmony with the spirit of the times.

The pressing need of gastrology to-day is a greater harmonization of the subject itself with the general conditions of life of the individual. By this is not meant the relation between local organic states and the general organism, but rather that a greater regard should be held for the connection between the various functions of the digestive tract and the channels through which all such influences as instinct, tendency, acquired tastes, perverted views, and enforced environment operate. It will not be sufficient to indicate that such and such a local condition exists. It will rather be necessary to regard more closely the personal equation which renders these states possible, for most individuals are living under the same conditions, and are subjected to the same insults of life.

It would be refreshing then to be able to turn to some field of activity calculated to throw light upon these problems. For years liberal gastrologists have felt, and clinical experience has taught that in each individual case of chronic dyspepsia—using this term as a generalization—there have been certain nervous influences, certain tendencies, directing and shaping the local functional activities. These conceptions have always been more or less vague, but nevertheless have been insistent. Beyond determining, if possible, the priority of nervous phenomena or the functional phenomena, very little was done. The diagnosis of neurosis or organic disease depended upon this decision, but the conclusions drawn were in most cases uncertain and unsatisfactory. The natural bent of the investigator was many times the chief determining factor. We are in a position to-day to approach these problems with greater confidence. I refer

in this connection to the work done in the last decade by Langley, Eppinger and Hess, Petren and Thorling, Fulta, Newbergh, Nobel, Kahn, Bauer, Schiff and Ebstein, Polowsky, Hess and Konigstein, Herring, Lommel, Hamburger, Aschner, Westphal, Heyrovsky, Bergman, Rössle, Benecke, Stierlin, Kraus, Marburg, Schüller, Van Yzeren, Lichterbelt, Solis-Cohen, Hemmeter. So much of this literature which is widely scattered, is given here for those whose interest is broad enough to stimulate them to pursue the subject further. The investigations have not been especially directed to the digestive processes, but they deal with problems which have a very direct bearing upon the etiology of gastric and intestinal diseases, and thus should recommend themselves to the very serious consideration of gastroenterologists. The intense physicochemical attitude exhibited in recent years toward all alimentary diseases has developed anatomical conceptions which, important as they are, cannot explain the fundamental principles involved in the production of the organic changes. The functions have been more or less neglected, and it is in a redirection to these that the importance of the work cited above lies. It attacks the diseases at their source, and it renders it possible to follow their development as a result of tendencies inherent in the individual.

The criticism is made that the work done so far has been entirely experimental, that the results obtained are vague, that the whole subject is hypothetical. This may be true, but whatever of fundamental value has been obtained harmonizes so well with what observing clinicians have all along instinctively felt, that it is well worthy of serious consideration. In the conceptions of vagotonic and sympathicotonic dispositions we have something tangible, sign-posts which may lead to something definite. The real value of these conceptions lies in the fact that it is possible by them to trace and demonstrate the channels through which the various insults to the digestive tract of habit and environment operate. Knowing these in each individual case, it is obvious that we may be in a position to reduce the objectionable effects of such often unavoidable insults to a minimum. The days have passed when we may content ourselves with vague references to neurasthenia and hysteria. It has been fairly definitely established that an individual may possess a certain exaggerated reactional trend incorporated in his autonomous or sympathetic nervous systems. In the normal individual these two systems counteract each other. There exists a state of equilibrium. Should, however, the one system or the other be natively hypersensitive, there will result a certain disharmony which will reveal itself in functional disturbances of the organs supplied by these systems. In the case of the digestive tract, its secretory and motor functions are completely under their control, so that whatever may be the insults offered to the tract, the response or defense to these insults will depend in the last account upon the reactional trend of the controlling mechanisms. This is entirely confirmed by clinical observation, for we know that there is a fairly definite tendency toward the development of certain chemical and physical grouping of gastric diseases. There are a number of signs and symptoms by which the individual reactional trend can be recognized, and it should be determined in every case of secretory or motor anomaly, for without this knowledge no conception can be complete.

Functional change precedes and determines structural change in the course of normal evolution for purposes of adjustment to the environment. It may do the same in pathological development. Exaggerated secretory or motor gastric functions, if continued long enough, will result in the various abnormal structural conditions that we know. A large proportion of our chronic dyspepsias are not the result of conscious neglect, habit, or abuse. They are the result of conditions forced upon the individual by the exigencies of life. These can operate only through the channels mentioned. In these cases the ordinarily accepted local measures of treatment can only be palliative. Ultimate recovery will depend upon an adjustment between external influences and internal reactional weakness. Exaggerated local measures may do more harm than good, in that they concentrate the attention of the individual upon results and not upon the causative factors, and there can be no doubt that as this phase of gastrology becomes more and more incorporated in the broader conceptions of the subject, the various fanciful arrangements of diet and impressingly ingenious instrumentation will be largely eliminated.

The deleterious effects of hyperfunction have been sufficiently recognized for other organs. An overstimulated and palpitating heart will eventually succumb to structural changes. A continuous high blood pressure will result in arteriosclerosis. Excessive renal activity will end in anatomical lesions of the kidneys. In the same manner an organ so far removed from willful control as the liver, will respond to abuse in proportion to the strain placed upon the general organism. Cirrhosis will appear rapidly as a result of alcoholic excesses in those individuals whose nervous systems are subjected to exceptional tension. In all these conditions treatment is directed toward the channels through which the causes operate, to a reduction of the intensity of reaction to the environment. If this is so for organs which are absolutely autonomous in their functions, how much more so must it be true for the digestive tract, the activities of which are dependent upon individual tastes and desires.

The greatest need in gastroenterology at present is a return to the functions, not in the sense of finer discrimination of pathological variation, but in the broader conceptions of etiology. The gross anatomical has so occupied the professional mind during recent years, that this phase of the subject has been neglected. It has almost seemed a confession of ignorance to mention it. The time has passed however when reference to vague conditions, such as Stiller's universal asthenia, will suffice. In the more definite knowledge of the constitutional trends inducing visceral hypo- or hypertonicity, we possess potent methods of analysis which will have a very practical bearing, especially upon prognosis and treatment. It will probably not be possible to establish in each individual case the well marked signs of vegetative nerve stigmata, but it will be possible to determine the tendency to hypo- or hyperfunction dependent upon these systems. The vagotonia of Eppinger and Hess is the extreme form of inherent weaknesses present in many of the cases of so-called chronic dyspepsia. The dyspepsia is but the local manifestation of hypo- or hyperfunction which in turn can be traced to its ultimate cause. Here lies the possible solution for many vexed problems. Much light may be thrown upon such conditions as dyspeptic asthma,

pseudo-angina, cardiac spasm, pylorospasm, fatal acute indigestion, persistent anorexia, acute dilatation, gastric vertigo, nervous hypersecretion, nervous diarrhoea, and the whole gastric acidity question. In an indefinite way the hypothesis had already been practically accepted. The whole question of universal asthenia would depend upon these conceptions. What other interpretation can be given to the reflex theories of gastric diseases, due to chronic appendicitis, gallstones, etc.? Even the concrete problem of duodenal ulcer is involved, but as Rössle wisely remarks, no cause can be operative unless the primary favoring disposition is present in the individual. It is the determination of this disposition which is the all-important task, and the time has passed when reference to this phase of digestve diseases can be regarded with indifference.

In fifty per cent. of the gastric acid secretion is psychic secretion, then fifty per cent. of the causes of abnormal secretory disturbances of the stomach must lie beyond the organism. These causes can be operative only through the channels here mentioned. In the past this element has been regarded rather as an interesting phenomenon. In the words of Rosenheim, we knew "*herzlich wenig*" about it. In the light of the latest developments, it assumes an intensely practical interest, for it should be remembered that this part of the secretion may hold the balance of power in the determination of a given pathological condition, not only functional but organic as well. Should there be any doubt as to the value of these conceptions we have but to recur to experience gathered in any gastric clinic. A large proportion of the cases here encountered exhibit the common syndrome composing hyperacidity and hypermotility. It is the most frequent combination known in this vicinity. The majority of these cases will yield to a consistent course of bromides and hyoscyamus, frequent small meals, and alkalies. The alkalies here are merely palliative. The effective work is done by the drugs. The frequent feeding supplements the latter, not by hypernutrition as is usually supposed, but by enforcing upon the individual a certain relaxation at frequent intervals, thus relieving the tension under which he is existing.

The considerations here offered have passed beyond the stage of mere speculation. The results of the work cited above harmonize so well with the facts of clinical observation that a practical application of the same becomes imperative. It means that a most useful work of the gastrologist of the future will be to determine in each individual case the inherent weaknesses as evidenced in constitutional trends which render universal causes operative. In modern communities all are subjected to more or less the same insults. A certain proportion succumb to these insults—not because they have weak digestive organs (a stomach with hypersecretion and hypermotility can hardly be called weak), but because there is inherent in them a constitutional liability to react excessively to the ordinary irritations of life as induced by habit, accident, or environment.

It may be that further experiment and observation will modify the views now held in regard to the activity of the vegetative nervous system. Enough has been done, however, to stimulate interest and to demonstrate its value for gastroenterology. Nor is this limited to the neuroses. It explains, as no other theory does, the pathological development of many pronounced organic lesions, always excepting acute or chronic inflammatory ones. It shifts the attack upon the neuroses themselves from result to cause. It will eliminate the personality of the diagnostician from the differentiation between neurotic and organic lesion. If given stigmata are found, there can be no question as to diagnosis. Its value for prognosis and treatment will be far reaching, for it will enable us to foretell with a certain confidence, what the final stages of a given tendency will be, provided the causes are not removed. Treatment will be enlarged. It will be diverted from local meddling and machination to the broader conceptions of fundamental and unmotivated science.

The time has come for a division of labor in gastrology. There will be those whose personal bent will always compel them to immediacy and localism. It is a restricted field. There will be those also whose vision is more far reaching, whose interest in the subject forces them to a consideration of the causes of animal behavior from original tropisms, the development of the simple reflex arc, the establishment of habitual neural paths, down the line of evolutional progress to the final introduction of the psyche, this last not always to the advantage of the individual digestive comfort.

MISTAKES MADE IN TAKING AND INTERPRETING BLOOD-PRESSURE READINGS.*

By GEORGE RICHTER, M.D.,

ST. LOUIS.

PROFESSOR OF MEDICINE, NATIONAL UNIVERSITY; VISITING PHYSICIAN, CITY HOSPITAL, ST. LOUIS.

The taking of blood-pressures has become so universal and its merits have been discussed so widely that further reference to it may seem unnecessary. It has assumed the character of a fad in which the laity is getting much interested. As in all such cases there is a tendency to take everything for granted and to ignore limitations, to overlook essential points, and to overestimate the value of the method.

It is interesting to note that such an eminent authority as James Mackenzie, in the latest edition of his classical work on diseases of the heart, criticizes the applicability of the method and questions the results. Another author of equal prominence, Ludolf Krehl, says ("Erkrankungen des Herzmuskels," 1913): "We have estimated blood-pressures, maximal and minimal, amplitude (pulse-pressure), and the product of pulse-pressure and frequency. One discovers thereby some interesting facts, and possibly more yet of importance may be learned. But for practical purposes, it seems to me, we cannot learn more at present by this method than by simply counting and palpating the pulse, observing respiration, and, above all, studying the whole individual." It would be tedious to quote all the modern authors who insist upon the limitations of this method, though they all recognize its relative value if used with proper circumspection.

It is not my intention to discuss here the various theories involved or to tire you with a repetition of the various methods used, the mercury-, the spring-, the diaphragm-, and the self-registering instruments, the importance of the size and proper adjustment of the armlet, the tactile, oscillatory,

*Paper read before the St. Louis Medical Society, April 12, 1914.

sensory, acoustic, graphic methods of determination, the difficulties in estimating diastolic pressures in aortic regurgitation, the meaning of pulse-pressure as denoting the difference between systolic and diastolic pressures, the mean pressure placed by various investigators close either to the diastolic or to the systolic pressure, and also the difficulty of finding the respective pressure in congenital arterial anomalies, in irregular pulses, and in those rarer cases where no brachial pulsation is audible, or a radial is impalpable. But I wish to emphasize facts often repeated by many observers and persistently forgotten or ignored.

Determining factors in creating blood-pressure are: the condition and force of the heart, the condition of the arterial wall, the resistance of the periphery, to wit, the contraction of the arterioles, the width of the capillaries and veins distal to the armlet, due to the play of the vasomotor nerves and also influenced by the tension of the surrounding tissues (subject to temporary changes), the physical condition of the blood itself, its relative viscosity, and finally the total amount of blood circulating, in plethora and anemia. It should be understood that a change in any or several of these factors may alter findings under otherwise normal conditions.

Blood-pressure varies perceptibly in the physiologic state with age, sex, time of day, before and after meals, defecation, micturition, menstruation, posture of the body, lifting of limbs (not only active but also passive), and also with atmospheric pressure. The psychic interest of the individual is of remarkable importance, and so is the temperature of the room. An undressed person in a cool room shows a materially higher pressure. Physiological differences are observed again in relation to work, to training, to individual development, to activity of the brain.

Let us add to this the fact that the blood is not evenly distributed in the body in proportion to the extent of vascular territories, but that by a most changeable vascular tone the blood-supply to the various organs is regulated according to their functional and nutritive need, and we may picture to ourselves the possible variations in health, if we endeavor to be exact at all.

Now let us consider some pathological conditions. With an increased pulse-rate, pressure may either rise or fall, as seen in cases of tachycardia and of increased tone of the vagus nerve. The rule is, normally, that an average pulse-rate will show the highest pressure. Pathologically a very weak heart, just short of complete failure, may exhibit a very high pressure, where peripheral resistance is increased and the weakened heart adds with each contraction additional, if small, amounts of blood to overfilled and distended vessels. This is Sahli's "high pressure stasis."

A high pressure may be due to a permanent, "healthy," compensation. An apparently normal pressure may be due to an ominous break of such a compensation.

Mental excitement of any kind, stimulation of sensory nerves, great pain increase pressure, and the same is true in the case of mental worry, and of all colics. Pressure disappears again after the attack is over, as in lead colic. I have not encountered yet a single case of increased blood-pressure during the intervals of a lead colic, and I have seen a great many sufferers of this class.

It has been stated and denied that arteriosclerosis is accompanied by increased pressure.. Right here is a pitfall for the careless observer. A soft rubber tube with a thick wall is less easily compressed than one with a thin wall. And we know now that the muscular layer of the arteries of some healthy persons is thicker than that of others; this seems particularly so in young athletes.

But now in arteriosclerosis we observe a pathological thickening of the wall, eventually with deposits of lime salts, even bony substance. And if we consider the fact that arteriosclerosis rarely extends over the entire arterial tree, that it is regional and may be confined to the vessels of the limbs only, or to those of the mesentery, or of the brain, or of the kidneys, etc., the determination will become so much more difficult. A pipe-stem brachial (with a normal radial) may simulate an immense arterial pressure, while in fact it is very low. In such cases the taking of the pressure is a somewhat dangerous proceeding. Infraction of the arterial wall, thrombosis and gangrene, also permanent palsies have been observed following such violent compression.

It is a fact that some arterioscleroses exhibit a high, others a low, or at least a moderate, pressure. This has been referred to the condition of the kidneys and some have imagined that disease of the kidneys is associated with a high pressure. But it is certainly not always the case. Of late the old accepted teachings as to chronic affections of the kidneys are being reconsidered and revised. Pathological findings were misleading and did not correspond to clinical experience. Widal, Castaigne in France, Krehl, Romberg, Volkard, Jores in Germany and many others are discussing the matter. There are ailments due to retention of nitrogen, others due to retention of chlorides and perhaps sodium, none of which ordinarily shows a primary high pressure, and a group of hypertension nephritides accompanied by sclerosis not only of the arteries of the kidneys but of the larger part of the vascular system. There are, besides, a number of chronic cases with a persistent albuminuria which are often practically harmless. In the latter, tension is not increased. In the course of time these groups become complicated by various changes in the kidneys, implicating the parenchyma as well as the connective tissue. In acute nephritis, however, blood-pressure rises high. At autopsy we view the ultimate results and little that would explain the clinical picture. It is the battlefield, the scenery of the stage after the play is over and the actors are gone.

In hypertension nephritis hypertrophy of the heart and great arterial tension are observed, frequently with only slightly marked changes in the kidney-tissues, with little edema and albuminuria. Its anatomical type is the "contracted kidney." The other types, nitrogen and chloride retention, are not primary kidney diseases, it would seem, but the former due to a metabolic disturbance, the latter to disease of the vascular intima.

It must be insisted on again that disease means in the first place disturbance of function, disturbances which may escape the anatomist as well as the bacteriologist. And to recognize such disturbances the study of the pressure in one brachial artery aids but cannot decide very much.

In certain affections of the heart as well as of the kidneys there appears a more or less extended edema, which to some degree will interfere with a proper determination of pressure, while the constricting cuff presses away the water in the tissues. It should be remembered that such an edema may

be difficult to recognize, because it may be present without showing any pitting on pressure. Very large quantities of water may be stored in the muscles and fat without appearing in corresponding amount in the subcutaneous tissue. After intravenous infusion (in the dog) about 68 per cent. of the water infused is discovered in the muscles and 18 per cent. in the skin, while, on the other hand, after feeding chlorides an average of 75 per cent. of it is found in the skin against 7.5 per cent. in the muscles (R. Magnus). Such an "occult" edema is discovered by the great loss in weight under the influence of diuresis and becomes evident by weighing the patient from time to time.

How far the direct effect of mechanical compression of an artery will alter real pressure by vasomotor reflex remains to be determined. That mechanical irritation of a vessel is apt to produce a marked local effect is observed when making an intravenous injection. As soon as the vein has been punctured it collapses, and when one has the misfortune to have the needle glide from the vessel one finds it difficult to insert it again. The pressure within such a vessel is certainly reduced to a minimum—locally.

The exclusion of an amount of blood from circulation (by constricting a limb) alters the heart-beat and affects pressure perceptibly. We make use of it in the treatment of angina pectoris, where it lowers (sometimes elevates) pressure and usually slows the pulse-rate.

The Katzenstein method of testing the function of the heart is based on the observation that on digital compression of both femorals blood-pressure in the healthy will rise by 10 to 20 mm. Hg., while the pulse-rate remains the same. In a weak heart, however, pressure remains on the same level or is lowered, while the pulse-rate is apt to increase. Also the absorption of very large amounts of water (intravenous infusion, excessive drinking) lowers blood-pressure normally.

Elastic constriction of limbs, as in the Bier hyperemia and by the Esmarch bandage, stimulates the depressor nerves with an irradiation into the vagus. Now it is quite noteworthy, and not sufficiently considered, that such a reflex action appears also where there is no evidence of heart disease, more promptly in some persons than in others. And in not a few the change in pressure becomes so pronounced that it is impossible to arrive at a definite figure of pressure. People with such a pronounced reflex irritability are often endowed with a greater nervous irritability in many directions, their psychic excitability adds to misleading findings, generally in the sense of depression. The first case in whom I ever observed this was that of a young overworked lawyer, a junior partner in a big firm, whose pressure in the left arm was first 120, on second trial 100, then 60—all systolic, of course—and when I looked up at him I perceived that he was about to swoon. After recovery, a long rest, and a journey, his pressure was found unchanging, normal, 130.

In the study of a long series of cases I have attached a separate "Tycos" apparatus to each arm and taken the pressures on both sides in quick succession. Very many cases were controlled simultaneously by at least two physicians who had some experience in this line. We found a large number of cases with a marked difference between the two arms, in a few cases not less than 15 mm. Hg. Though the true cause of such differences in a healthy person is unknown, it certainly proves that the heart has nothing to do with it. There must be a potent determining factor somewhere in the periphery, probably influenced by vasomotor (constrictor and dilator) nerves. At any rate, in comparing notes from time to time of the same individual, pressure should be taken always of the same arm.

Still, when we find a material difference between the two arms, we should always be on the lookout for a certain pathological condition; in one case I was enabled to diagnose aneurysm of the aorta by this very sign, other symptoms being ambiguous, and the diagnosis was confirmed by the *x*-ray.

I may be permitted to assert in this connection that the apparent difference in time in the radial arteries, the sensation on palpation as if the pulse in the one radial appeared later than that in the other radial, is in the great majority of cases an illusion. Simultaneous sphygmograms of both radials in such cases prove it, and one will find in the special literature on such cases that what I assert was observed long ago. Most authors believe the illusion to be due to the peculiar shape of the wave on the side of the diseased vessel. Here one obtains a slow rise and a slow, uninterrupted fall of the wave. But it does not hold good in all cases. Within the last three years I have seen about 25 cases of aortic aneurysm. Of 17 I have taken pressures and sphygmograms (mostly bilateral). The tracings were in about one-half the cases normal with a somewhat lowered apex on the side of the aneurysm. It is assumed that the sounds heard in the cubital artery (auscultatory method of Korotkoff) during compression above, between systole and diastole, are due to vibrations of the arterial wall, caused by the quickening force of the pulse-wave. On the side of the aneurysm one listens often in vain for those sounds. Evidently the undulating wave fails to cause such a vibration. The origin of the undulation I believe to be a local paresis of the arterial wall.

In all cases of aneurysm but one there was a marked difference in pressure between the two sides. And this only exception proves again that a difference of pressure must not be taken here for a fixed rule. There is no such thing as a fixed rule in the symptoms of any disease.

But what is it that imparts to the touch the sensation as if one pulse was earlier than the other? It is the fact of lower pressure on one side, a less pronounced impact from the pulse-wave and, according to a well-known psychophysical law of relation between stimulation and sensation (namely, perception), a strong stimulus is perceived earlier than a weaker one. It is the same with the doctrine that in chronic lung disease of one side the respiratory movement of the diseased side appears to lag behind that of the healthier side. In a large majority of cases a bilateral pneumogram has proven to me that this is an optical illusion, due to the diminished and therefore less conspicuous expansion of the diseased side.

Unusual values of pressures in perfectly healthy people are not quite so frequent as normal pressures in sick people. They call, of course, for a specially careful examination. They are often found rather low in young trained athletes and elevated in old people. In the latter high pressure is not necessarily due to arteriosclerosis or to hypertension nephritis. In old people fat tissue with its large number of capillaries has disappeared, the glands of the skin are reduced in number, all, or nearly all

of the glandular functions have lessened, and there is also a decrease in lung-circulation due to old-age emphysema. This means again a reduced number of capillaries. The skin shrivels and is dry, so that a cut in the skin produces only little blood—shivering old age! The flow of blood from the arteries into the veins is impeded by such a deficit in capillaries, the blood wells up in the arteries which by development of connective tissue in the place of plain muscle-fibers have lost much of their elasticity and become firmer (except in atheroma); an "old-age anemia" does not sufficiently compensate the condition and blood-pressure rises. But that is not a disease, it is a condition!

The influence of the variable width of peripheral vessels, due to continuously changing stimuli, must not be overlooked. According to the law of Poiseuille, the dilatation of a small artery will increase the flow of blood at the ratio of the fourth power of the radius of a vessel, while pressure itself increases in simple arithmetical proportion.

I approach now a question which presents a perplexing feature: the so-called diastolic pressure which is generally stated to be of predominating importance. How far systolic pressure will affect diastolic pressure is quite obscure. Diastolic pressure is defined as the minimum pressure occurring during a revolution of the heart. Can it be referred to the pressure prevailing within the heart during its diastole? Impossible! For that is, at least in its beginning, practically negative. The minimum arterial pressure is always decidedly positive. It can be due only to conditions prevailing in the periphery, in one peripheral artery, for, as I have very often found, the diastolic pressure in one radial may differ from that in the other by ten or fifteen mm. Hg., or from that in the two femorals to a similar degree at the same time. It would seem as if diastolic pressure did, aside from peripheral conditions, rather indicate the pressure prevailing at the valves of the aorta at the instant of their closure and represent the condition of the root of the aorta, not of the heart itself. Therefore aortic disease exhibits pulse-amplitudes, similar to those of aortic regurgitation.

We determine "systolic pressure" during diastole, or dilatation of the artery, its expansion with the pulse, and "diastolic pressure" during the contraction of the artery, or the artery's systole. Such an opposite activity of elastic and muscular fibres in the arterial wall while the pulse-wave with the blood itself passes through it, is bound to exert an influence upon pressure-values to an unknown extent. Otherwise the "diastolic pressure" (aside from its mysterious character) betrays peripheral conditions in a most interesting way. It points to certain alterations in the blood-current more clearly than any other mechanical contrivance.

We employ the sphygmomanometer for diagnostic and prognostic purposes with greater benefit, when we base either on frequently repeated determinations in the course of days or weeks. The data obtained are not of any value at all if all sources of error are not carefully avoided and concomitant symptoms considered. We shall then, and only then, gain most useful information, not quite so readily gotten without it.

Mention has been made that the state of the nervous system may affect blood-pressure, thus it would serve diagnostic purposes also in this direction. Psychiatrics and the doctrine of internal secretions receive some help from the method. Willi Schmidt has observed that for instance in pre-senile dementia, in hebephrenia, and catatonia the injection of adrenalin, which in the healthy raises pressure, will not do so, and that when an improvement occurs adrenalin injection will again raise the pressure.

One has expected too much from the method and disappointment is bound to follow. Surely, a single blood-pressure reading gives a meaningless figure and may be quite misleading. Rules based upon such readings prove absolutely nothing. Averages established have no more bearing on a given case than statistics would have under the same condition. The fad of generalizing by deductions from ever so many isolated observations made in so complicated and still quite obscure a matter as the meaning of a single pressure discovered in one brachial artery is detrimental to clinical medicine. Only by most complete study of each and every single case can we hope to arrive at useful results. To this complete study belongs the estimation, under proper precautions, of blood-pressure, which with available methods gives valuable relative, but never absolutely correct and reliable data.

NEUROSIS AND PURPOSE.

By GEORGE MITCHELL PARKER, M.D.,

NEW YORK.

It is necessary to view the neurosis as a mode in life; to compare it with other expressions; to read its meaning in relation to those others and to life in general, but not to scrutinize it as a strange, isolated mental epiphenomenon; then to ascertain the direction of this, for no meaning is possible until a direction of the movement is defined and its termination fixed. Until this chiefest thing is seen, no real value can appear from an analysis. An American philosopher has advised thus: "Never break a thing open until one is sure of the terminal facilities." Unless there can be gained from the neurosis a view of its end or purpose, any breaking into it is inadvisable. The justifiability of this paper rests upon an attempt to isolate the neurosis as purpose.

For the moment drop purpose in relation to the neurosis and consider it in relation to life. The purpose of life is purpose; note the gap which strikes the mind, and the question, "Purpose for what or motive for what?" It seems impossible in an applied sense to define purpose or motive without an object. Even in an abstract way, some moral object stuff usually exudes at the attempt. If we substitute "striving" for "purpose," we again question "Striving for what?" Instantly material vestments hang before us, to be striven for. But that is not an answer. Back of the vestments must be something greater, for which they stand, something which they symbolize, a universal object, not a petty gewgaw of the moment but an everlasting and desired possession.

A definition of the conditions of purpose will make things more clear. No purpose exists individually; the social context is always given. No act, however apparently autonomous, which historically lacks the relation to others, which does not take into account the reality of the world as construed or having been construed by society. The ancient formula has no truth which gave life as an adaptation of the inner to the outer; just this it is not, nor has been. Growth has not come out of mere adjustment or adaptation. These words feebly ex-

press a result; they do not describe the real activity of the individual nor do they touch the purpose. Prehistoric man was seeking no adaptation when banging his hatchet against the durable framework of his animal contemporaries. A river channel as an erosion or the remains of water confluence from a subsidence of the earth's crust may show an adaptation; but this same river may urge no adaptability to those nations bordering it, for history has written the erasure by man of every material adaptative boundary. Had man's purpose been adaptation, he would now be embalmed in the deposits of ancient stratifications. Self-preservation—another hoary term—goes little further. It does recognize, implicitly, others. This the purpose of life, though fossilizing were avoided, the head measurements and culture of the Lake man would now present. Self-preservation is negative; it is defense, not attack, and attack alone means growth. It involves isolation, separation; it denies society. Civilization gives it the lie.

In both these interpretations of life something lacked. The term needed came not from biology but from the truest and most intuitive in his psychology of our philosophers in his expression of the basic purpose of life as "Will to Power." With this, man's relation to man instantly emerges; his attacking of reality, not adjustment to the reality; nor for overcoming reality in itself but out of the will to power, a power psychologically expressed in its relation to another man. Here is no formula of man versus reality but first as man versus man; not out of a self preservation but out of a striving for power which exceeds that of his fellow. Here is purpose as the first term and final term. Yet this can be read only in a social context. This is the sole disability affecting this equation; that it reads in the mass but not in the individual and this because we the readers are individuals and halt with a blurred vision when hurt. How we have built ornate systems of religion with ample moral assurances against just such self revelation is no part of this work to tell. Sufficient that some skulking depreciatory sense of wrong hangs at the heels of such an interpretation of life's purpose, something immoral, and the will to power, in morals as in armor, demands the best and most appreciative, which this is not. We are saved, as usual, by ourselves from a painful meeting with a naked purpose. Yet, whatever Peters we may be in our denials, the mark of this purpose is to be found and its sources discovered. In this field Adler of Vienna has been a pioneer and the fundamentals under question are those that have yielded to his examinations. Man conceives his personality largely as envisaged in an outer surface body. So valued is this that his Deities have been cast on the same mold. This is his last word of approval. Yet his life processes lie beneath. Latter years have seen these better translated. Single organs have been expressed, not in terms of a single function, but as composed of diversified and interlocking functions. Systems of organs have been defined bearing to one another clear relations. The rate of function has been found widely variable in the single organ and in the systems of organs. Follows the compensation theory which has shown in the absence or diminution of one function that a correlated part attempts to compensate for it. But back or this lies the work of Adler, who for the first time expressed the true picture of compensation in his "Organic Inferiorities," in which an organic inferiority pushes its rate of functioning above normal in a compensatory effort. The important factors in Adler's equation are the inferior function below the line and the compensation leading to function above the line or level of normal. This difference in level, then, is not merely compensation; it is more than the equivalency implied in this word. It is strictly an over-compensation, a going beyond. Adler's studies of function showed further, if the over-compensation failed in the organ directly involved or in the specific function of this organ, that the same movement was carried elsewhere in some correlated function. In all this a general biological mode in the presence of an organic inferiority, a general biological heritage. It remained within these limits organic, because the over-compensation in an organic way was efficient or reasonably efficient. Where the organic over-compensation failed, here Adler's theory carried out an admirable evolution. Into the background of consciousness given by the organic life, into this context of consciousness the uncompensated inferiority comes as a feeling differentiated in the general sematic sensory background. These sensations, long described by neurologists as feelings of insufficiency, incompleteness, yet never explained, adapt themselves to the framework of his hypothesis. Adler makes them the mental inferiority sublevel and constructs his superlevel of over-compensation in a corresponding range of mental attitudes. The organic pattern is used to construct his psychic model. Here is where the individual first touches society, for in society is afforded that matter without which he can not over-compensate, and this pattern is the parent. We know the range of the child's growth never keeps pace with the necessities of reality; each month brings a more difficult world and reveals more plainly the feeling of inferiority in this deficit. As parental care diminishes, this confrontation is more harsh. The parent stands at once as conqueror of this reality and as the most immanent of reality to the child. Overcoming or gaining the supremacy over the parent is then to overcome reality. The parent stands as the original object of the over-compensation, born of an inferiority sense but so far removed from its original organic substratum as to make its picture dim and not reasonable. Here is the strength out of weakness or Nietzsche's own formula "Good from Evil." Here is the core of Purpose, which is a pattern of life and upon this the psyche grows. This is teleology and without it structure is impossible.

Yet it is immediately apparent that such a purpose cannot find an abiding working out of reality. It is fictitious, viewed as a goal, a supremacy of this kind. Yet this fictitious goal is the goal of the child as it was the goal of man in the childhood of the race; nor in man or nations does it completely die unless they die, and in both a breath may blow it into life. Life, then, written in these terms of teleology varies as this purpose varies. At one stadium it fertilizes, at another it checks growth, and the differing lives must display these differing relations to this one purpose of supremacy; whether it persists as the goal, this fictitious supremacy, or whether it has been forced to make some working arrangement with reality, society. A closer psychological differentiation at this point, while to be desired, would not add to the exposition of the purpose.

It is then possible to arrive at a division by this teleological divisor. One group abandons the goal,

another pursues it. A simple separation of this type lacks in any fine distinctions. But it is worth while recalling that intricate classifications usually have rested upon superficial observations and rarely have touched the deeper generalizations which break groups into major not minor masses. However, a possible didactic tone must not blur the fact that the fictitious goal is never entirely abandoned. Vestiges of it constantly reappear, compromises are effected; only the needle in the one group swings toward the reality of society more constantly than it deviated in the direction of the fictitious supremacy of "Being All, Having All, Willing All." In the other group the goal remains supreme. Yet in this second group, with a like teleology, the course toward the fictitious supremacy varies in directness and in the degree of accommodation to society or reality. The more direct the course, the less is the accommodation; the more devious presents a closer approximation.

Although society cannot be credited with any understanding of this group, she has discriminated against them always and this because of their faulty accommodation to life. Possessed of differentiating criteria beyond this, we have in front of us a rapid distribution of this inchoate mass. Of these criteria the fictitious goal stands in front as first and now predicated as defining and dominating the group. The goal, the supremacy, is revealed only by the course leading to it, for it has, as a singular and distinguishing feature, a localizing beyond the consciousness of the individual; like the Covenanters it has sought the solitudes for worship; not of a God, however, but of itself as a God. To the individual, this purpose, this supremacy, this God is hidden. But to an Alexander, a Napoleon, a malefactor of great wealth, their goal, their ambition is cameo cut in consciousness. The object is in front of him and is not diffuse in its allness. Also at times Alexander sat at the feet of Aristotle, Napoleon lived keenly aware of Josephine, while our malefactors have each seen the limitation of their candle power. But the unconscious, fictitious goal knows no other than self; even self may be merged with God and Fate is their handmaid. With an unconscious goal, it is obvious that further knowledge has had to halt until some method of intrusion into the deepest part of the individual was attained. We have seen Adler's derivation of the psychic over-compensation out of an inferiority basis and this as universal. In his work in psychanalysis out of dream interpretations he arrived at a teleology, his own and not shared by Freud, in which the dream presented the unconscious formation as built out of the over-compensation and arranged in a movement toward the supremacy of the fictitious goal. The unsuspected ramifications about this goal, its intrusion into the center of psychic life, its domination of all activity were exposed. Out of its analysis the courses toward the goal so well submitted themselves to close analysis that marks were yielded which identified similar conscious courses and defined the variations of such paths covered in life and toward a goal revealed only by its approaches. In his admirable work "Uber die neurotische Charakter," Adler has given an ample and sound foundation for these concepts. These paths, discriminated against though not understood by society, become explicable as one follows them from the unconscious outward. Because they are the outer accommodations of the individual, because they are his "symptoms," it is now the moment for their scrutiny and a possible grouping on a basis differentiating their type of movement and their relative accommodation to society, using for this these criteria possessed of familiar marks out of their analyzed prototypes of the unconscious. All this that the purpose may be made recognizable, that the goal may be distinguished by the movement leading toward it.

Two groups go over the direct route to the supremacy, in which none or little accommodation is made to reality or society: the psychoses and the criminal mass. It would seem obvious that qualifications of both groups are in order at this point: yet there should be held in mind that here no denial is entered of determining etiological factors which appear, for instance, in general paresis, in psychoses associated with organic brain disease, in the infective-exhaustive group, or in the toxemias; nor that consideration has failed among the criminal mass, as in the feeble-minded delinquent, or the epileptic, or the alcohol group, or the "occasional offender," or the resultants of economic pressure so dear to the sociologists. The contention here is that whatever may be the etiology in this mass, it has served to exaggerate the movement toward the fictitious goal in a degree which has made their course direct and has annulled any accommodation to society.

A more definite objection will be made on the ground that the psychoses and the criminal mass are not related except in the popular mind. As modes they are as apart as the poles, but in this, as in other analogies, inner similarities are blurred by outer differences and, because the latter are to be seen and discriminated as visible attributes, separation rather than unification dominates. This is not to be overcome by insisting upon a common unseen goal, but by presenting both groups as exhibiting a like directness and a like maladjustment to society even though achieved by unlike methods.

The psychotic carries into his conscious life the reality of his unconscious. No other reality exists for him. His course is terribly direct; nothing stands in his way. He has no need of social verification; the data of experience do not encumber him. His fictitious goal of supremacy is a pillar of cloud by day, of flame by night. No trace is left of the conditioning inferiority on which his over-compensation was built. This may seem a possible interpretation of the paranoiac, or a maniac, or a precox subject, but where can it lie in the depressive phases? Here it lies concealed beneath the formidable expressions of sin or grief or deprivation, so formidable as to break all bonds, to destroy the deepest of obligations, to depreciate all others and isolate self with expressions of regret and accusation so false as to remove their possessor further from society. As Shaw says of the Christian martyrs, "pride is their besetting sin." Asceticism and vanity go together. The criminal has a like driving toward the supremacy, but in his unconsciousness there has been less elaboration; also it rises and falls. His urgency is the greater out of a better defined and more persistent inferiority feeling, yet one in which the over-compensation demands a social verification in acts, which, depreciative of property and person, appreciate and feed the supremacy. The firm construction of the psychotic supremacy fails, for it is characteristic of the criminal that a repetition of the act is demanded to maintain the supremacy. Only at the moment of the act does the reality of the supremacy erase the reality of society. Yet where the movement toward the goal is urgent, where no other mode of over-compensation can be equally effective,

this expression will repeat itself and one confronts the problems of recidivism. In single or multiple acts, however, his course has been direct, even though not sustained; his accommodation to reality, society, has been lost though only for the moment. Thus, with two divergent modes in the psychotic and in the criminal, based on differences in the unconscious formation, an outer course is made toward a common goal with a similar directness and a like maladjustment to society.

In the second group the course toward the fictitious goal is less direct, hence the accommodation to reality is more usual. Society does not discriminate against this group; yet they are marked off from the larger mass. To apply to them the term of Neuroses or psychoneuroses is an admittedly poor effort at description; yet it will have to stand, for here the group is not being considered in a nosological sense; it is in the aspect of purpose that the present formulation is attempted. The tolerance of society would indicate that the modes of this group are those of society, or like them, for to Society those not speaking her tongue are Barbarians. To define the situation further, it is recalled that society does discriminate against the psychotic because his supremacy has grown so massive and rigid as to carry his unconscious reality out into the reality of society; against the criminal, because open, urgent over-compensation of his inferiority, constantly required for his wavering supremacy, strikes monotonously at society as the object of his depreciation, his solitary mode of over-compensation. Hence, it is fair to assume in this second group a less rigid supremacy than the psychotic and a less massive inferiority than the criminal. A less rigid supremacy means, of course, a considerable and unsatisfied inferiority which constantly demands over-compensation in the movement toward the fictitious goal, yet with none of the terrific urgency of the criminal whose inferiority stands out as the greatest when read from his peculiar modes of over-compensation. With a less rigid supremacy than the psychotic, which cannot carry into consciousness, with a less urgent inferiority than the criminal driving relentlessly toward over-compensation, it is plain to see how this group have taken the easiest route of non-offense to society in developing modes which are not direct but devious, with methods not simple in their openness and immediacy, but complex because covered and disguised. So far as society is concerned, they seem to "pull through" in Mark Twain's words describing the Sabbath with Adam. They thus get by, because their methods are calculated to conceal the true movement toward the fictitious goal. These methods deserve a brief attention, for in them is lined the contour of the neurotic. They are, in the first place, archaic; they go back to childhood, infantile structure, when all were more supreme than since; and we dimly recognize them as they reappear in our neurotics and denominate them as childish, which, of course, they are. Only they are well fitted to carry supremacy under a cover, and the child, when a man, appears weak, timid, humble, anxious, or perhaps foolishly defiant and nasty and proud or critical; a nuisance in general, a martyr or a devil. A man, he may be as a woman; a woman, as a man. Adjectives die in such descriptions. Beneath or with these archaic unfitnesses some personal end is concealed, bound to appear if not too severely sought; it may again appear in garments of sober, mature gray, but the tinsel and color lie below always. And we tag them as selfish, a good word, but out of place here, where we have known the real fictitious goal as of a magnitude to make so simple a word as "selfish" blanch and tremble. On top or near the surface the neurotic carries a wonderful line of moral (sic) life insurance in the form of protections, otherwise called phobias, compulsions, etc. Usually these do not appear at first, although in one group of neuroses they give the dominant tone. Being the least social or the least fitted to society of all the contour marks, their necessary concealment leads to the most puzzling attitudes and reactions. Yet, all these marks only go to make up the contour and a bare part of that. But the relation of this contour to the body of the neurosis has been the immediate and important thing. The final relationship of the neurosis to life, to the social body has been defined in the terms of that purpose, supremacy, which never dies and is ever sacrificed to. In this setting the neurosis stands revealed as an unsuccessful endeavor to maintain the supremacy of the inividual in the midst of a harsh and resistant social body. The neurotic has failed where the psychotic has won and the criminal for the moment excelled.

The practical bearing of the neurosis, thus defined, is that a structure is placed before one in which the successive formative stadia are exposed. The final result is a complex reaction which presents for treatment. Holding to the line of purpose, the central object to be attained is the destruction of the fictitious goal by methods which shall bring it, with its material, into consciousness, and hence into adaptation to society where it cannot persist. To get the material requires intrusion into the unconscious. Psychanalysis is the method here, but not the psychanalysis of Freud. Their basic differences will be handled in a later paper. It is here sufficient to iterate in the final words, that no fairer chance is open for therapeusis than in a situation where the pathology is found to be identical with a false direction and restitution to normal is to be gained by erasing a false structure to permit a normal movement toward a goal which is adapted to society.

23 East Seventy-seventh Street.

PAINLESS PARTURITION.

By M. W. KAPP, M.D.,

SAN JOSE, CAL.

So much has been said recently regarding "twilight sleep" in parturition, its benefits and its dangers, that I feel it my duty to give to the medical profession my experience in the last three years with a method of producing a condition of shockless and painless parturition.

I have practised medicine, as a general practitioner, for twenty years. I have always had a good obstetrical practice. The dread and agony of the parturient mother has always worried me. Motherhood is such a sacred condition and it should be such a happy condition from its first moment through all its stages. With so many the dread of the hours of labor depresses them and without any question has its depressing effect upon the child. I feel that I have been able during the last three years to lighten the burdens of the mother very materially.

I use my method as freely in the most humble home as I would in the hospital. It requires no corps of trained assistants. The country doctor can use

it as readily as the city doctor who attends the "four hundred."

When I am called to a woman in labor and I am sure that the pains are real labor pains I wait until the expectant mother shows some signs of distress, if it is a first confinement. That is so she may know what labor pains really are. If it is a case of a mother who has had one or more children I do not wait for the pains to become even severe. I am presuming that the patient has been properly prepared for accouchement. I then give the patient (1/12) one-twelfth grain of heroin hydrochloride hypodermically. Within twenty minutes she will feel drowsy and no longer feel the sting of the pains.

At this time I sit down by the patient and explain to her the need of her bearing down when she feels the contractions. Between pains she will often fall into a light sleep. When I find she is progressing nicely I often go away and make a call or two, or at night I may lie down for an hour, leaving a nurse or someone with the patient who will call me if I am needed. If labor is getting well advanced I stay by the patient's side and watch every advance carefully.

The effect of one injection of one-twelfth grain heroin usually lasts about three hours. Some very severe cases need more heroin before the end of three hours. I simply watch my patient and if the pains are getting severe again I sometimes give another full dose. Again I may give only one-twenty-fourth or one-thirty-sixth of a grain. I aim never to have more than one-twelfth of a grain of heroin in action at one time. I have found that one-twelfth of a grain is the best average dose. I tried one-sixth of a grain several times and it spoiled my case by retarding the pains. One-twelfth grain inhibits the sensory nerves but does not affect the motor nerves. I have used as high as three and one-half doses in one case. I rarely need more than one or two.

I have used it in about one hundred cases all in general practice. I have no trouble with the babies being blue, at least no more than I ever have had. Any long case of labor may cause a child to be exhausted when born.

Heroin properly administered will hasten labor rather than retard it. It lightens pain so the mother if properly directed will aid in the expelling of the child. The use of morphine and scopolamine will retard labor almost every time. I have had no severe cases of hemorrhage while using heroin.

The mother usually rests very quietly after labor and has much less shock than by the old method. Many doctors seem not to appreciate the condition of shock after labor. I have sometimes used a little chloroform at the last part of labor, but that is not necessary if the heroin has been properly managed.

I have had a few cases of inertia of the uterine muscles in which heroin did not seem to do much good, but by using divided doses of pituitrin labor was properly completed.

I do not claim that my methods and my technique are the best or are correct. I write this so that others who have better facilities to develop the correct method may be urged to do so. It is by far the best method of lessening the fear and pain of the lying-in chamber that I have ever been able to find, and best of all I can use it in my general practice without fear.

The Freiburg method and the nitrous oxide and oxygen methods are good but they are only to be used in hospitals. I believe that if heroin were used with the same technique as the morphine and scopolamine treatment the results would be equal, and there would be no danger involved.

RECOVERY FROM BICHLORIDE OF MERCURY POISONING.

By F. F. DURRAH, M.D., and G. W. WHITE, M.D.,

WASHINGTON, D. C.

INTERNES, FREEDMAN'S HOSPITAL.

As recovery from poisoning by bichloride of mercury is infrequent, the following case seems worthy of record:

A. H., A Cuban woman twenty-two years old, was taken very ill on Friday, July 24, after having taken two 7½ gr. bichloride tablets intentionally while under the influence of whiskey. She was seen by a physician on the following day and was sent to Freedman's Hospital on Sunday night, July 26. She had been vomiting almost continuously since she took the poison. She had intense pain in the abdomen and a profuse diarrhea. She had not passed any urine since she took the poison. The patient was catheterized but no urine was obtained.

Examination showed a woman of dull face, very taciturn, sullen, mind clear, teeth loose, gums sore and bleeding. Examination of the heart and lungs were negative. There was tenderness on palpation over the abdomen. There was complete suppression of urine. Blood pressure: systolic, 105 mm. Hg., diastolic, 70 mm. Hg. Decapsulization of kidneys was considered by Dr. J. B. Nichols, the visiting physician to the ward, but was deferred.

The patient was given hot packs for twenty minutes three times a day. Lithium citrate gr. v dissolved in water, four times a day for two days; piperazine 15 gr. to 16 oz. of water given during the day for six days; pituitrin, ♏ xv, hypodermically every four hours for four days, then twice daily for three days; rectal irrigations of hot decinormal salt solution twice daily; potassium chlorate and hydrogen peroxide were used as a mouth wash.

On the second day in hospital, the fourth day after taking the poison, the patient voided 2½ oz. urine, which on examination showed albumin and a few granular casts. She continued vomiting and complained of severe pains in the abdomen. Mouth and gums continued to bleed. She slept very little during the night.

On the third day the patient did not void urine, but we obtained two drams per catheter. Condition poor. No uremic symptoms evident.

On the fourth day the patient voided six ounces of urine. Hot packs discontinued; hot water bottles placed over region of kidneys. On the fifth day the patient was much improved, vomited only a little during the day. Diarrhea had ceased. Bismuth subnitrate, in large doses, was given after the vomiting had ceased.

On the sixth day the patient was able to take liquids and soft foods and retain them. She continued to void urine. After the sixth day, she grew gradually better and all the gastrointestinal symptoms disappeared. On the twelfth day examination of urine showed a trace of albumin, no casts.

The patient was discharged on the eighteenth day fully recovered.

Polycythemia Rubra.—H. MacCormac reports the case of a male aged 64 years, in whose family history there was nothing of importance. His health had generally been excellent. No previous illness. The present condition began six years ago, when his friends told him his face looked flushed and blue. About this time he had his first attack of articular gout; since then he has had several other attacks. He has also had sciatica. The rubicund condition of his face and extremities had become more marked. The small blood vessels could be seen very distinctly on his face and there was a general reddish blue color which was also well marked on the mucous membranes. Apart from a feeling of lassitude his general condition was fairly good. The spleen was very considerably enlarged. Blood count: Red blod corpuscles, 8,500,000; white blood corpuscles, 9000; hemoglobin, 130 per cent.—*Proceedings of the Royal Society of Medicine.*

Medicolegal Notes.

License to Practice Special Branch of Medicine or Surgery.—California St., 1911, p. 1437, provides for the board of medical examiners issuing a certificate to anyone to practice a special branch of medicine and surgery, who shall have at the time of the act going into effect, practiced it 35 years, 15 of it within the states and shall pass a practical examination, consisting of a demonstration in such special branch, and thereafter qualify by effecting a cure. It was held that this provision is based upon a proper classification, viz., ability acquired by experience, and shown by an examination, notwithstanding the persons to whom it applies had violated the law by practicing without a certificate. The provision of the act was held to show a legislative intent to admit certain persons to practice a special branch of medicine and surgery who have previously violated the law, not, however, because they have violated the law, but because of an acquired experience in given branches of medicine or surgery. The provision was held constitutional. Whether cancers, tumors, malignant growths and cutaneous diseases are so correlated that they may be classed as such a special branch was a question of fact under competent evidence.—Bohannon v. State Board of Medical Examiners (Cal.) 140 Pac. 1089.

Evidence of Shock from Fright.—In an action for personal injuries from being knocked down by an automobile, the testimony of a physician that it is almost impossible for any physician to state just the extent of an injury from a shock, because it sometimes shows up 10 or 15 years afterwards, that one cannot tell the extent or duration of it in the future, and that there are cases of shock from fright where the condition has become permanent, was held to be admissible to show what suffering will accrue from the injuries in the future.—Rugenstein v. Ottenheimer, Oregon Supreme Court, 140 Pac. 747.

Qualification as Medicine Expert.—In an action for personal injuries it was held that the fact that an expert witness was not a physician regularly licensed to practice in the state did not militate against his competency as an expert. The only object of license is to prevent an unqualified person from practicing medicine and surgery; but a man may be ever so learned and well qualified to give an opinion, and yet not be engaged in practice. The fact that the witness had been licensed to practice medicine in another state, and had been so engaged since then, was competent evidence for the consideration of the court in determining as to the qualification of the witness.—Rugenstein v. Ottenheimer, Oregon Supreme Court, 140 Pac. 747.

Right to Compensation from County.—A large number of cases of "infantile paralysis" having broken out in a county, the state board of health ordered a duly licensed physician, who was a member of the board of health of the county, to quarantine the disease. He did so, attending to about 250 cases of the disease. It was held that he was entitled to recover from the county the actual expenses incurred by him and the reasonable value of his services.—Shidler v. York County, Nebraska Supreme Court, 146 N. W. 949.

Right to Compensation from County.—A regularly licensed physician was under contract with a county to give medical attendance to the inmates of the poor farm and the prisoners in the county jail, for which he was to receive the sum of $5 per month. Smallpox became prevalent in the county to such an extent that it soon became epidemic, and the physician was directed by the chairman of the county board and board of health to quarantine all those afflicted with that disease in the county, to fumigate their homes, and take all necessary measures to provide for its suppression. He treated 132 cases of smallpox. His actual expense in connection with this service was $260, and he charged the county $726 for his professional services. The board disallowed his claim. In an action against the county he was awarded $790.35. On appeal by the county, it contended that the plaintiff could not recover because he was a member of the board of health. "It is easy to understand," the court said, "why the members of the board of health should receive no compensation for serving thereon, but it would be difficult to understand why a physician should be called upon to serve the county in suppressing an epidemic and contagious disease without compensation. Many cases are cited by appellant to support the contention that an officer must perform all the duties of the office for the compensation provided by law; however, those cases are not decisive of this controversy. The better rule is announced in Spearman v. Texarkana, 58 Ark. 348, 24 S. W. 883, 22 L. R. A. 855, where it is said: 'A physician who is a member of a board of health may recover reasonable compensation for purely professional services which any other physician might render, rendered by him under direction of the board of health without any express agreement for compensation.' " The judgment for the plaintiff was therefore affirmed.—Plumb v. York County, Nebraska Supreme Court, 146 N. W. 938.

Evidence as to Result of Injuries.—In an action for personal injuries alleged to have been caused by the sudden starting of a street car, it appeared that the plaintiff suffered a miscarriage four days after the accident. The defendant argued that the evidence did not warrant the inference that the injury sustained on the car caused or contributed to the miscarriage. The argument was that the miscarriage might have been caused by lifting the child onto the car step, or by weakness following two previous miscarriages, the second of which was followed by curettement of the womb, and that there was no definite evidence pointing to the fact, or the inference, that the sudden and unusual starting of the car was the proximate cause of the miscarriage. One physician testified that the injury produced the miscarriage, and others testified to the contrary. The plaintiff testified that her health was good before the injury, and that immediately after the injury she began to suffer pain until the miscarriage occurred. It was held that the question whether the miscarriage was caused by the injury was properly submitted to the jury, which found for the plaintiff.—Atwood v. Washington Water Power Co., Washington Supreme Court, 140 Pac. 343.

Liability for Medical Services to Employee—Right to Terminate Contract.—A building contractor, one of whose employees had received a severe bodily injury, called his own regular physician and surgeon over the telephone and instructed him "to come and take care of the injured man." When he gave this instruction he knew that the employee's injuries were of such a character as to render it necessary to immediately remove him to a hospital. The doctor at once responded, and took the man to a hospital. For the purpose of inducing the hospital authorities to receive him the doctor stated to them that the principal for whom he was acting would be responsible for the payment of the hospital bill of the injured man. It was held that the master was bound by such acts and declarations on the part of his agent. Subsequently, and while the patient was yet incapable of being removed or discharged from the hospital without great danger to his life or health, the master gave notice that thereafter he would not be responsible for care and treatment "from now on." It was held that the master had no right to thus terminate his liability. Under the circumstances, it was an implied condition of the contract that the master could only terminate his liability to the hospital by removing the patient, or when he could be dismissed by the hospital without serious danger to his life or health, or by showing that the injured man had means out of which the hospital could and should have collected its pay.—Omaha General Hospital v. Strehlow, Nebraska Supreme Court, 147 N. W. 846.

Liability of County for Operation on Prisoner.—It is held that, where a physician, at the instance and at the request of the sheriff of a county, performs a surgical operation upon one who is a prisoner in the custody of the sheriff, an action cannot be maintained by the physician against the county to recover the value of such services, where there is no law authorizing the sheriff to bind the county under such circumstances.—Nolan v. Cobb County, Georgia Supreme Court, 81 S. E. 124.

Action for Services.—In an action for compensation for services rendered to one run down by one of the defendant's cars, an instruction to the jury improperly allowed the plaintiff to recover for services rendered some time after the accident as for those rendered in "first aid." As, however, the plaintiff had a verdict for $476.67, which was the total amount of his demand with interest, it was clear that he did not recover merely for the "first aid" given, but upon the ground that he rendered all his services upon the employment of the defendant and its undertaking made through its authorized agent to pay him therefor, and the error was therefore harmless.—Sylvester v. New York, N. H. & H. R. Co., Massachusetts Supreme Court, 104 N. E. 437.

INTRACAPSULAR RUPTURE OF THE LONG TENDON OF THE BICEPS BRACHII.

INTRACAPSULAR rupture of the long tendon of the biceps has been considered an unusual occurrence and has received but slight attention except in some of the newer and more recently revised surgeries; but Fièvez (*Arch. Gén. de Chir.*, February, 1914) contends that it is by no means so infrequent as has been supposed and contributes an extensive study of the subject, also touching upon the medico-legal side of the question. Now that we also have a Workmen's Compensation Law, cases of disability from this source will undoubtedly come up for adjudication, hence this work is especially worthy of notice at this time.

He finds that intracapsular rupture of the long tendon furnishes a triad of symptoms which consist of: (1) Tumor of the long head, (2) abnormal perceptibility of the long tendon below the anterior border of the deltoid, and (3) the putting of this tendon into more or less strong tension during contraction of the biceps. The tumor is situated in the anterior brachial region, along the course of the long tendon. Its volume varies with the muscular development of the subject, is enlarged transversely from the short head to the cephalic vein, which it lifts forward, is continuous below with the biceps muscle and above with the long tendon. If the muscle is in repose the tumor is soft, depressible, mobile, and without adherence to the skin or deep parts. In passive extension of the arm it does not disappear but is somewhat reduced, and remains soft. In active contraction it grows harder, increases in size, and becomes a little more prominent. When the contraction is opposed it becomes hard, increases still more in size, and becomes immobilized. From these clinical characteristics it is evident that the tumor is composed of healthy muscle, heaped upon itself. The abnormal perceptibility of the tendon below the deltoid is the capital element of the syndrome. Normally this tendon becomes fleshy at the point of emergence from under the deltoid, and appears to the exploring finger as a spindle progressively increasing in size. In intracapsular rupture, however, three or four centimeters of the tendon are appreciable to palpation, frequently to view also, below the deltoid border; the tendon has the form of a well-rounded cord, more or less tense in repose, but rigid in opposed flexion of the forearm. At the moment of the accident the patient ordinarily perceives a cracking accompanied by a sharp pain in the upper part of the arm; this latter being the principal cause of the functional impotence occurring immediately in the injured member. On the following days, although the pain and functional impotence may retrocede quite rapidly, there appears occasionally a more or less extensive ecchymosis occupying the anterior region of the arm. A considerable number of these cases have been operated upon and surgeons have found an intracapsular rupture of the long tendon.

Before taking up the cause of intracapsular rupture, Fièvez calls attention to the fact that anatomists have often noted anomalies in the insertion of the long head, such as into the bicipital groove, humeral tuberosities, or the articular capsule. Whether this is due to congenital malformations or to pathological modifications following intracapsular rupture of the tendon can be settled only by reviewing the published accounts to see if, in these dissections, the relations of the tendon to the anterior border of the deltoid were normal or not. According to the published accounts intracapsular rupture of the long tendon is rare; but Fièvez, in examining 450 patients in a hospital service, found his syndrome present on an average of 1 in 45 cases, with the maximum of frequence in the male and in the right arm. In the dissecting room he found it once out of ten subjects dissected. He explains this difference in percentage on the ground that there are two forms of the affection—acute and chronic; this latter sometimes with a début and evolution so silent that it is hardly noted by the patient.

The stages leading up to rupture within the capsule were well shown in some of the cases dissected. In one, the tendon was frayed; in another, there was rupture of some of the tendinous fibers and progressive infiltration and destruction of its mass; while in a third, the lesion was definitely constituted, the tendon being ruptured near its superior insertion and reinserted into the capsule of the joint. In one cadaver both stages were shown, before rupture of the tendon on the left side, and after rupture on the right. Arthritis sicca, with ecchondroses, osteophytes, and intra-articular villosities, was present in all the cases. In the late cases there was also periarthritis and inflammation of the bursæ. Thus he believes that there is first an arthritis, with the formation of ecchrondroses and osteophytes, together with infiltration of the main body of the tendon within the joint. In the process of contraction of the muscle and in the various movements of the arm—abduction, adduction, etc.—the edges of the tendon are rubbed and the tendon gradually weakened so that rupture may occur upon severe strain if the process is not very far advanced, and on slight strain if the destruction of the tendon has been considerable. The first constitute the acute, and the latter the chronic, or medical, cases. While the biceps tendon is being weakened, and perhaps finally ruptured, the arthritis continues its destructive action, opening the capsule, causing thickening and perhaps per-

forating the subacromial or subdeltoid bursa. It is thus easy to understand the production of the syndrome of this lesion: The long head of the biceps has been detached from the glenoid tubercle and glenoid ligament, and the part of the tendon normally concealed in the joint, of which it constitutes an active ligament, has escaped through the bicipital groove. Thus is explained the presence of some centimeters of tendon abnormally perceptible under the deltoid border. Since the tendon has slipped, the muscle, due to the slight tonic contraction of its fibers, forms the tumor felt and seen, and finally there is increased tension of the cord during contraction because the tendon has been held by its synovial sheath which has been devaginated to the maximum and has become hypertrophied. Later the tendon becomes reinserted upon some portion of the capsule, usually in or near the bicipital groove.

Coming to the medicolegal side of the subject, there are three types of cases: those in which (1) the traumatism is severe, and seems sufficient to have caused the rupture of even a healthy tendon; (2) the traumatism is insignificant, the arthritis being manifestly everything in the causation of the rupture; (3) the traumatism and the arthritis may be considered equal factors in the production of the rupture. The question then arises whether the antecedent condition of the tendon and of the tissues in and around the shoulder joint should be considered in deciding the amount of damages to be allowed in cases of intracapsular rupture. The compensation law in France was passed in 1898, and in 1902 the Court of Appeals rendered the following decision: "The determination of the indemnity depends upon the salary effective of the worker injured, and the ability for work which the accident leaves him. The inferior condition in which the victim was before the accident is of little importance from the point of view of the determination of his actual condition." Discussion has been keen in France upon this point.

ANISOTROPIC FAT AND ITS EXCRETION.

For a long time considerable interest has been aroused by the discovery in the various tissues of substances resembling fat but differing from the latter and from lipoid bodies by possessing anisotropic properties, and presenting the appearance under polarized light of glittering droplets enclosing a black cross. Kaiserling and Orgler found these bodies in the diseased wall of the aorta and in the kidneys, and regarded them as the product of a peculiar form of myelin degeneration. They also isolated these bodies from the urine.

A. Lawrynowitz (*Zeitschrift für klinische Medizin*, Vol. 80, Nos. 5 and 6) has studied the question of the excretion of anisotropic fat in relation to its deposition in the tissues. He regards the so-called myelinosis of the kidneys as an expression of the general tendency of the organism to store up the esters of cholesterin whenever the metabolism of this substance is disturbed. From the diagnostic viewpoint the presence of anisotropic fat in the urine indicates in all probability a chronic parenchymatous degeneration of the kidneys. It is particularly in amyloidosis of the kidney that anisotropic fat is excreted in the urine. It has been found that the experimental introduction of anisotropic fat into the tissues is accompanied by a destruction of the parenchyma and a degeneration of the connective tissue. The author regards the deposition of anisotropic fat in the kidneys as a complication of nephritis, which complication moreover creates a vicious circle by giving rise in turn to a further degeneration of the renal cells. These apparently cannot tolerate the presence of anisotropic fat deposited in them, and accordingly break down and set free the unwelcome guest. Of course this sequence makes the ultimate prognosis much more unpromising.

It appears that the source of the anisotropic fat is to be traced back to cholesterin which in turn is derived from the food ingested. By dietetic measures therefore one may restrict the amount of cholesterin that enters the organism and thus limit the accumulation of this substance in the blood, which sequence is the rule in chronic inflammations of the kidney. In order to attain this object there should be excluded from the diet eggs, brain, cream, and other fatty substances.

"HEALTHY" LEAD WORKERS.

That certain individuals not only resist the deleterious action of race poisons but actually appear to thrive upon them is an observation occasionally made, and one which has no bearing on acquired immunity which is excluded by the conditions at hand. Thus often for some months a beginner in opium eating may have his somatic and psychic functions quickened, may take on weight, may be in a state of continual euphoria and accomplish great quantities of work with no demand for increase of dose. In the midst of an active outdoor existence, and upon a full diet, such subjects may even appear to be free from any unusual evidence of excretory obstruction. A thorough study of such cases, however, would doubtless warrant the conclusion that while no intoxication is manifest, a condition of latent poisoning exists and is demonstrable by various tests.

In recent years something of this sort has attracted much attention in the case of lead workers who as a class have benefited greatly by protective enactments. In the various lead trades the proportion of men in apparently perfect health is considerable and this fact may lead to wrong interpretations and laxity. It is known that the first evidences of lead poisoning appear in the blood picture and that the previously healthy worker may suddenly exhibit hematoporphyrinuria. Last summer before the Giessen Medical Society (*Deutsche medizinische Wochenschrift*, September 17) Schmidt dwelt upon the necessity of periodically testing the blood of all lead workers who seemed in good health. The number of basophile granulated erythrocytes gives an unerring criterion of the presence of latent poisoning and only in this manner can we arrive at a clear conception of the actual health of apparently healthy workmen.

Brain Fever.

In former generations the expression "brain fever" was so often and vaguely used by laymen and even by physicians that it is not easy at this late date to determine its exact scope. Old text-books made it synonymous with active hyperemia of the brain, but it should also have comprised meningitis, encephalitis, sinus phlebitis, etc. It would seem proper now, perhaps, to limit the term to cases of cerebral hyperthermia induced by puncture or other lesion of the nucleus candatus; this phenomenon sometimes follows surgical intervention. Last summer at a session of the Medical Section of the Jena Society of Naturalists and Physicians (*Muenchener medizinische Wochenschrift*, September 22) Berger described a case of frontal lobe puncture for diagnostic purposes in a woman with symptoms suggestive of brain tumor. The borings showed absence of tumor tissue, but there was a considerable escape of fluid from the subarachnoid space, with the ventricular cavity apparently unchanged. Next morning the hitherto afebrile patient was found to have a high temperature (nearly 39° C. at times) which persisted for six days, when it fell suddenly to normal. In the interim the patient felt well and meningitis could in general be excluded. The puncture had been directed so as incidentally to estimate the width of the lateral ventricle, and the author explains the occurrence of fever by the entrance of the borer into the caudate nucleus. Some of the borings contained grey matter resembling that which characterizes this nucleus.

News of the Week.

Health of the Canal Zone.—During the month of July the total number of admissions to hospital of the employees in the Canal Zone was 1,424, an admission rate of 366.57 per thousand; the rate for June was 381.09, and for July of last year 513.87. The death rate from disease was 4.12 per thousand. During August the admission rate was 367.59; that for August, 1913, was 543.71. The death rate in August was 3.26; that for the same month last year was 4.31.

For Uniformity in Food and Drug Laws.—The Chamber of Commerce of the United States of America, a body composed of representatives from about 600 local boards of trade, chambers of commerce, and trade associations, widely distributed throughout the United States, has taken up the study of the subject of uniform food and drug regulation. For this purpose a special committee was appointed in July, and its first meeting was held at the headquarters of the Chamber in Washington, October 8. The committee is composed of Willoughby M. McCormick of Baltimore, A. J. Porter of Niagara Falls, John A. Green of Cleveland, B. L. Murray of New York, and Theodore F. Whitmarsh of New York.

Foot-and-Mouth Disease.—Fourteen States are under quarantine on account of the prevalence of foot and mouth disease in cattle, and interstate shipments of cattle, sheep, and swine are absolutely prohibited from the States now quarantined. Stock cannot even be sent from one infected State into another. The quarantine declared does not prevent shipment of stock from unaffected districts to slaughter houses within the quarantined area.

Killed in or by Automobiles and Other Vehicles.—Forty-three persons were killed in New York City during October by vehicular traffic, according to the report of the National Highways Protective Society, twenty-five being children under sixteen years. Automobiles killed twenty-eight, trolleys eight, and wagons seven. In the State, outside of this city, automobiles killed fifty-three, trolleys fourteen, and wagons three. In New Jersey automobiles killed twenty-two, trolleys three, and wagons three. Twenty-four were killed at grade crossings in New York, and nine in New Jersey.

Killed by Wood Alcohol.—Upward of twenty Vermont farmers died last week as the result of drinking whiskey purchased at a village drug store. The district is under prohibition regulation and the men of the neighborhood get their supply for the Sunday booze at the drug store. The supply at this particular store was simply flavored wood alcohol, and the result is many deaths and several cases of blindness.

Physical Defects of Students.—An examination of the male members of the freshman class of Indiana University, made by the physical director, Dr. F. P. Holland, has revealed the fact that about 17 per cent. of the students are physically defective, the chief faults being flat chests and pes varus. Of the female students less than 11 per cent. were defective.

American Red Cross Surgeons.—The American hospitals at Gleiwitz and Cassel are doing such satisfactory work that the German Government is about to request that three more American surgeons be sent to Germany. In case that is done the Government will turn over another large hospital in Gleiwitz to American supervision. Commissions in the Russian army were given to the surgeons of the American Red Cross units assigned to service in Russia. The commissions given to the two senior surgeons carry the rank of General, while the four junior surgeons received the rank of Colonel.

The Virginia State Medical Society held its forty-fifth annual meeting in Washington, D. C., on October 28 and 29. The following officers were elected: *President*, Dr. Samuel Lile of Lynchburg; *Vice-Presidents*, Dr. Samuel B. Moore of Alexandria, J. T. Buxton of Newport News, and J. W. Preston of Roanoke; *Secretary*, Dr. Paulus A. Irving of Farmville; *Treasurer*, Dr. M. W. Peyser of Richmond; *Delegate* to the A. M. A., Dr. Robert C. Bryan of Richmond; *Alternate*, Dr. S. S. Gale of Roanoke. The meeting in 1915 will be held in Richmond.

Society for the Advancement of Clinical Study.—The annual meeting of this society will be held at the Academy of Medicine on Wednesday afternoon, November 18, at 5 P.M. This society has been organized for the purpose of maintaining a bureau of information which will furnish to resident and visiting physicians definite information regarding the clinical facilities of the hospitals and laboratories of the city of New York. For this purpose a bulletin board has been installed at the Academy of Medicine in charge of a special clerk, and on this all hospital clinics, both medical and surgical, are posted daily. These facilities will afford physicians an opportunity to witness operations and clinical demonstrations without resorting to extended inquiries at the various hospitals.

Extension Work in Public Health Education.—The Weekly Bulletin of the Department of Health says that the Bureau of Public Health Education is cooperating with a number of teachers in the training schools and high schools of this city in giving

their students an insight into the work of the Department of Health. The students use one of the bureau's monographs as a text book in their work in hygiene and in municipal government, following their book studies by a visit to the health exhibit on the fifth floor of the department building, 139 Center street. In addition to this, the bureau has arranged for extension lectures to the students in their school similar to the lectures given in the courses arranged for the Health Department's employees. Work of this sort is bound to lay the foundation for sympathetic and effective cooperation between the Department of Health and the public at large.

The Alvarenga Prize.—The secretary of the College of Physicians of Philadelphia writes that in the notice sent last week of the award of this prize, the title of Dr. Sheffield's essay should have been: "Idiocy and Allied Mental Deficiencies in Infancy and Early Childhood."

Dr. William Seaman Bainbridge of this city has been elected an honorary member of the Cincinnati Academy of Medicine.

Hospital News.—Barnes Hospital, St. Louis, was dedicated with appropriate exercises on October 27, by Bishop E. R. Hendrix of Kansas City. Addresses were made by Dr. George Dock and others. During the exercises a bronze bust of the late Robert A. Barnes, donor of the Hospital, was unveiled.

Dr. Norman MacLeod has been appointed superintendent of the Newport (R. I.) Hospital. He is the first medical man to occupy this position.

Dr. John M. Peters, superintendent for twenty-five years of the Rhode Island Hospital, Providence, was the guest of honor at a complimentary dinner and reception at the Turk's Head Club on October 28. Two hundred medical men and lay friends of Dr. Peters were present.

The following physicians have been appointed on the medical board of the New Haven Hospital: *Consulting Physicians and Surgeons*, Drs. William H. Carmalt, Thomas H. Russell, Louis S. De Forest, Gould A. Shelton, Frank H. Whittemore, William H. Hawkes. *Attending Physicians*, Drs. Charles J. Foote, George H. Blumer, Charles J. Bartlett, Wilder Tileson. *Assistant Attending Physicians*, Drs. H. Merriman Steele and Charles W. Comfort. *Attending Surgeons*, Leonard C. Sanford, Joseph Marshall Flint, William F. Verdi, John W. Churchman. *Assistant Attending Surgeons*, Drs. E. Reed Whittemore and Raynham Townshend. *Neurologist*, Dr. Max Mallhouse. *Laryngologists*, Drs. Henry L. Swain and Eugene M. Beake. *Assistant Obstetrician*, Dr. Richard F. Rand. *Pathologist*, Dr. Charles J. Bartlett. *Assistant Pathologist*, Dr. Max. R. Smirnow. *Chemist*, Frank P. Underhill; *Radiographer*, Dr. A. G. Bergman. *Ophthalmologist*, Dr. Henry W. Ring. *Dermatologist*, Dr. Eugene M. Beake.

Professor August Weismann, the well known biologist and author of the theory of heredity called by his name, died on Friday in Freiburg. He was born in Frankfort in 1834.

The Late Dr. Marx.—At a meeting of the Metropolitan Medical Society of the City of New York, held on October 27, 1914, the following memorial was ordered spread on the minutes, a copy to be sent to the family of the late Dr. Simon Marx and one to the MEDICAL RECORD. We, the officers and members of the Metropolitan Medical Society of the City of New York, wish to record our deep sorrow in the death on June 16, 1914, of our beloved friend and fellow physician, Simon Marx. We who have been associated with him in the medical calling for many years can best appraise those fine qualities of mind and heart which marked him out among men. As a physician he was gifted, learned, and industrious, commanding the respect of his associates by reason of his high attainments in that branch of medical science to which he had devoted the best years of his life. We mourn, however, not only the passing of a distinguished member of the medical fraternity of our city, but we feel stricken in the loss of one, whom all of us, without exception, cherished and honored as a friend, one to whom all of us could turn for counsel. To Mrs. Marx and her children we venture to offer this expression of our deep-felt sympathy in the great sorrow that has come to them, asking them to find some comfort in the circumstance that their loss is shared by an innumerable company to whom their husband and father was dear, alike as physician and as friend. Save for those nearest to him in his family circle, none can mourn Simon Marx more truly and unfeignedly than do we, his sorrowing associates in the high calling which his gifts enriched and his life ennobled. For the Society by the Executive Committee: Seymour Basch, Charles H. May, Gustav G. Fischlowitz, Henry M. Koles, Leopold Marcus, Seymour Oppenheimer.

Obituary Notes.—Dr. GEORGE STANLEY LYNDE of New York, a graduate of the College of Physicians and Surgeons, New York, in 1887, a member of the New York State and County Medical Societies, the New York Pathological Society, and the New York Academy of Medicine, and for many years a medical officer of the Department of Health of New York, died suddenly at the New York Hospital, on November 5.

Dr. DANIEL M. SHEEDY of Poughkeepsie, N. Y., a graduate of the New York University Medical College in 1888, formerly attending surgeon to St. Francis Hospital, of which he was one of the organizers, died at his home suddenly, from heart disease, on October 31, aged 49 years.

Obituary.

JOHN SHRADY, M.D.,

NEW YORK.

Dr. JOHN SHRADY, who died at his home in Stamford, Conn., on Wednesday of this week, was before his retirement one of the best known and most beloved physicians of upper New York. He was born in this city eighty-five years ago and was a graduate of the College of Physicians and Surgeons of Columbia University in 1861. After graduation he entered the medical corps of the Union Army and at the close of the war began practice in Harlem, where he lived an active professional life for over forty years. Six years ago he retired and made his home in Stamford. Dr. Shrady was a prominent member of the New York County and State Medical Associations from their foundation until their amalgamation with the older County and State societies, and served a term as president of the County Association. He was for a number of years editor of the *Medical Register*. He was a brother of the late Dr. George F. Shrady, for nearly forty years editor of the MEDICAL RECORD. Two daughters and two sons, Drs. Arthur M. and John E. Shrady, survive him.

Correspondence.

OUR LONDON LETTER.

(From Our Regular Correspondent.)

COLLEGES AND SOCIETIES—HARVEIAN ORATION—BANKS MEMORIAL LECTURE—REPORT OF ASYLUMS BOARD—WOUNDED AND REFUGEES—ARMY SURGEONS IN FRONT—UNIVERSITY VICE-CHANCELLOR—BACTERIOLOGY AT ST. MARY'S HOSPITAL—MANSLAUGHTER WITH HYOSCINE GIVEN BY QUACK, JUDGE'S CONDEMNATION AND THREAT.

LONDON, October 23, 1914.

WE are now in full working order in our hospitals and societies, most of the latter having met and begun the new session. On Monday both the Royal Colleges transacted business and we have had various functions to attend on every day at the institutions in which each has his own interest, and there are more to follow. The College of Physicians has the Harveian Oration which this year was undertaken by Sir Douglas Powell and at its conclusion the Bissett-Hawkins Memorial Medal was presented to Sir Ronald Ross for his distinguished services in the promotion of sanitary science. The College of Surgeons opened the demonstrations for advanced students and practitioners in the Hunterian Museum where Mr. Shattock showed specimens illustrating carcinoma. Mr. Colyer and Professor Keith followed in due course. Another exhibition is that of clinical cases shown by the Harveian Society. The Society of Tropical Medicine had previously had a paper by Sir David Bruce on African trypanosomes pathogenic to man and domestic animals. Next month Sir W. Osler will open a discussion upon "Enteric in War," and the prevention of diseases prevailing among troops is expected to occupy much attention during the session. The Royal Medical Society carries on its work in sections, some of which have already met.

Sir D. Powell's oration was the two hundredth and fifty-eighth since Harvey's time, but this did not discourage the orator who opened with the remark that year by year some advance in medical knowledge had taken place well worth reporting from its freshness and interest and its more or less dependence on his great discovery. Harvey might be regarded as the founder of physiology for, as had been shown by a previous orator, upon the discovery of the circulation of the blood, as upon a new *primum mobile*, rested all our knowledge of this and of pathology and not a little of what we know about the action of medicines. Yet it cannot be said that the idea of the circulation of the blood originated solely with Harvey, for the idea was floating about in the sentient atmosphere of thought by which he was surrounded.

Sir Douglas passed under review the functions of the blood in the tissues of living animals and pointed out that the circulatory and pulmonary mechanism were dependent upon it themselves. They were, therefore, subordinate to the continuous circulation of the vital stream which, so consistent in all its physical respects, so infinite in all its attributes and adaptations, dominated all the functions of life. Harvey, if he were living to-day, might with still greater conviction quote Leviticus: "For the life of all flesh is the blood thereof."

Sir V. Horsley delivered the third Mitchell Banks memorial lecture in the University of Liverpool, in the course of which he did not hesitate to point out that surgeons have not profited by Banks' teaching as thoroughly as they ought to have done, although they generally profess to follow it. Thus to make the removal of cancer of the breast complete Banks insisted on the removal of the axillary glands—a practice now usually followed. But to fulfill all known requirements by antagonizing all avenues of entrance of the disease it is as necessary to remove the supraclavicular glands and other tissues. Sir Victor said every such operation should therefore include: 1. Very wide removal of skin, breast, and margin of subcutaneous fat and fascia outside the gland edge, the pectoralis major, and the whole axillary contents—fat, fascia, and glands up to the edge of the first rib—in one mass. 2. Free removal of the supraclavicular fat, fascia, and glands. Few surgeons do this entirely and explantions are offered by some to justify the omission of some parts. Every such omission, Horsley said, was to him not only a violation of surgical procedure, but a grievous wrong done to the memory of Mitchell Banks.

Sir V. Horsley then took up the subject of hernia and showed that the operation he has been performing and known as his, completely fulfills the Mitchell Banks requirements.

Should a doctor confine all his interests in his professional sphere or should he rather take a share in all movements for the benefit of the public? There are many who advocate exclusive devotion to medical science, which they hold is amply sufficient for the most energetic worker and will reward all his zeal. As many, perhaps more, regard it as desirable if not even a duty of every citizen to promote his country's and his neighbor's welfare. Liverpool is grateful for the work done for it by the late Sir Mitchell Banks, which in no way restricted that for his profession. Discretion as to the work taken up and discrimination in the manner of doing would seem to suffice to produce harmonious results. Banks declared we must be more than prescribers of physic or dressers of wounds. "In my youth," he said, "I had it strongly recommended to me to stick to my profession and leave everything else severely alone. The life of a doctor was to see patients, do operations, order drugs, and collect fees. I thank God that I entirely repudiated this idea of my profession."

The annual report of the Metropolitan Asylums Board for 1913 has appeared and shows further extension of its functions in relation to the institutional treatment of the sick. It is responsible for the sick, debilitated, or convalescent children under the Poor Law, and provision has been so freely made that others have taken advantage of it. The Board, therefore, intends to exercise a closer supervision restricting these children's hospitals to cases requiring operations, non-tuberculous joint and bone disease, lateral curvature, and so on.

Since the casual wards have been under the Board its policy has been to keep the poor out of them as far as possible and distribute them among voluntary institutions to help them to return to ordinary life. The committee remarks that the man who makes himself a burden on the public deserves to be restrained by different measures more than many minor offenders who are dealt with. The use of antitoxin in diphtheria has continued and the intramuscular method is preferred. Deep injections in the muscles of the thigh were more rapidly absorbed than those in the gluteal region.

With refugees and wounded our hospitals and other institutions have been overwhelmed. The Red Cross and St. Johns Ambulance Association have

been strained to meet the urgent needs of fresh arrivals to pass them on to posts, private or public. Some 1,500 a day reached here last week and from 150 to 200 parties were sent out of London to various towns. One day 4,000 refugees were fed in a waiting room and in the evening another thousand arrived. Hospitals and other emergency buildings had to be utilized. Some Belgian doctors and nurses too came and took part in helping their compatriots.

Some 328 wounded from the siege of Antwerp were admitted in a couple of days into the London Hospital. Of these most were suffering from shrapnel wounds, some serious, but the majority slight. At St. Bartholomew's Hospital there were fifty or sixty more. Dr. Howarth, medical health officer for the city, superintended the management of detraining and conveying to hospitals by the motor cars of the Red Cross Society. Among the casualties no small proportion of the medical officers are numbered, knowing that they are facing the dangers as much as any rank in order to carry their help to the wounded.

Sir Wilmot Herringham presiding on Thursday at the meeting of the Senate of the London University received leave of absence to serve as consulting physician to health medical forces at the war so long as may be necessary. Sir Alfred Gould was appointed to act as vice-chancellor during Sir Wilmot's absence. A number of provisions were also adopted to prevent students engaged in military duties from being unduly prejudiced.

The bacteriological department of St. Mary's Hospital—always very active—reports having supplied 1,476,374 doses of vaccine for inoculation since the beginning of the war—an amount reckoned as equal to 160 gallons of the fluid. Another calculation has appeared, viz., that the typhoid bacilli alone if they could be placed end to end would stretch over a straight line one million miles in length, *i.e.* the distance to the moon and back twice over.

A man who kept a "home of healing" has been found guilty of manslaughter of a young woman who died under his treatment. Some interesting points came out in the trial. Dr. Wilcox, analyst for the Home Office, said he found in the body traces of some mydriatic alkaloid; the cause of death was paralysis of the stomach and exhaustion caused by the treatment. Asked if he would have sanctioned such treatment in the case, he said "certainly not," and on the judge asking would he in anybody's case he used the same words. Hyoscine (there had been evidence that this was the alkaloid used) was the same as scopolomine, very poisonous, five or six times as strong as strychnine.

The accused gave evidence on his own behalf and said he was an American and began using scopolomine in 1898, used it in morphine, opium, and alcohol habitués, at one time had charge of delirium cases for the city of Chicago, and out of 1,700 cases only seventeen died in eighteen months. His treatment was recognized by many physicians in America. Scopolomine could be used safely in delirium cases up to a temperature of 100 or just over. Higher it would increase delirium. In the drug habit he had given repeated doses of one-fiftieth of a grain, had put the patient to sleep in three minutes, had always been associated with physicians, and when twenty-six years old had the biggest drug business in America. Death from hyoscine would show the most culpable negligence. He knew more about it than any one hundred physicians on earth. He had advertised cures for consumption which cured 80 per cent. From 1886 to 1898 he was advertising a cure for rupture without operation.

In passing sentence the judge said the conviction would show that when ignorant persons undertake to deal in dangerous poisons, in spite of all the rhetoric, all the tall talk of cures and the wonderful system of treatment, and the unity of the infinite, and all that sort of stuff, a British jury, when people had been subjected to deadly poisons by incompetent persons, would go straight to the mark and say it was manslaughter. He was not about to punish prisoner severely, because he hoped this conviction would check such doings, and any who thought of following in the same line of business had better take note, because as far as he (the judge) was concerned next time the sentence would be heavier.

The sentence passed on this occasion was extremely lenient—only three months.

OUR LETTER FROM THE PHILIPPINES.

(From Our Special Correspondent.)

CHOLERA IN BILIBID PRISON—A DISINFECTING AUTOMOBILE—CARE OF THE INSANE

MANILA, September 20, 1914.

A SHARP little cholera outbreak in Bilibid Prison is very interesting as a contribution to the subject of "Carriers." The walls of the prison completely separate its inmates from the outside world under ordinary conditions, and protect them from ordinary infections. That none shall be introduced, all prisoners are quarantined for five days, and in the meantime are examined as possible disease carriers. No cholera carrier, as far as known, has gained entrance. But Bilibid is on low ground and was seriously affected by the present flood. On September 3 the rising waters stopped its sewers, rose above the level of its water closets and seats, put out the fires, and filled the space inside its walls with dirty water carrying the filthy washings of the low class native districts in the vicinity of the prison. The prisoners were necessarily drenched from working in the flood waters, which stood a foot deep in the cell houses and deep enough to swim in throughout the yards. This dirty water penetrated to all parts of the prison, and evidently got into the mouths of prisoners through swimming, handling wet articles, etc. High water was on September 3. On the evening of September 5 one man was taken down with cholera and on September 6 three more. One of these was a murderer awaiting death in the complete isolation of the condemned cells, but to whom the infection was undoubtedly conveyed in the flood waters by which they were partly inundated. On the 7th there was one case, but none on the 8th or 9th. However, one of the cases of the 6th slept in the same prison room with the kitchen force, which was found on the 8th to contain no less than 22 "carriers." These were promptly isolated, but more cases were expected from them as a secondary source. On the 10th four cases appeared, on the 11th four more, and on the 12th one. Since then no more cases have appeared, and it is thought that the outbreak is practically over, as the entire 2,500 prisoners have now been bacteriologically examined and "carriers" isolated. In all, about 3 per cent. of all the inmates of this prison were found to be cholera "carriers," which proportion does not differ materially from that so far found

to exist for the population of Manila as a whole.

One noticeable feature of the present outbreak has been the exceptionally low mortality. Of the 13 Bilibid cases, but three died, and of 183 cases which reached the acute contagious disease wards at San Lazaro only about 25 per cent. has died. Usually outbreaks here have a case mortality of in excess of 50 per cent., and some have resulted in death in 85 to 90 per cent. of all cases. The very large number of persons who are harborers of the cholera germs without apparently being affected, and the small proportion of those who die after developing frank symptoms of the disease would indicate the presence of a strain of cholera vibrios which is relatively slightly virulent and seems to have become adapted to a Philippine environment. The spread of cholera in the provinces has been threatened through laxity in handling the infection on the part of local authorities. Hence it has been thought best to handle all provincial cholera direct from Manila in all cases where the infection was not at once eradicated by the local authorities. To this end a cholera squad of some 25 specially selected men has been organized and put under an energetic Filipino medical inspector, who has so far had excellent success in promptly controlling outbreaks and destroying infections in the provinces.

A much needed facility in the Bureau of Health has just been installed in the shape of a disinfecting automobile, which accommodates the entire disinfecting squad of eight men together with the necessary disinfecting materials and apparatus. A vast amount of time had previously been lost through the use of mule carts, which consumed much time in going to and from places to be disinfected. This has been particularly noticeable lately, when cholera cases have been widely scattered and have occurred largely in the suburbs at considerable distances from the disinfecting stations. Any part of the city can now be reached by the disinfectors within ten minutes, which under present conditions and needs increases the working efficiency of the disinfecting gang by 50 per cent. The new disinfecting automobile will replace the mule cart service south of the Pasig. If it proves as satisfactory as is anticipated, the mule cart disinfecting service north of the river will be similarly replaced. Under present conditions there is a vast amount of disinfecting work to be done, and it means much to be able to rush the disinfectors to the place where needed with all the celerity of a fire engine.

A well organized movement is under way for the establishment of an institution for the care of the insane, of whom there are probably not less than 3,500 in the islands. The three institutions which now receive these cases can accommodate altogether but about 650, and none are modern or up-to-date institutions. They are merely places for incarceration and safe keeping rather than establishments for mental therapeusis. It is proposed now to take over the highly developed 600 acre experinemtal farm of the Bureau of Agriculture at Alabaug, erect the necessary buildings, and turn it at once into a sanatorium. Alabaug is a beautiful place, high, well drained, and with many improvements in the form of roads, piped water supply, and numerous buildings. It is about 17 miles from Manila, on the railroad and close to Laguna de Bay. It is understood to be regarded as ideal by the authorities of the Bureau of Health.

THE INTERVERTEBRAL FORAMEN.

To the Editor of the Medical Record:

Sir:—My book, "The Intervertebral Foramen," was reviewed in the May 9 issue of the Medical Record. In this work I attempted to give an exhaustive description of the normal histology of an intervertebral foramen and its adjacent parts. However, the foramen described and photomicrographs shown were from the cat, as stated in the text.

I have been in receipt of many letters and inquiries asking if these findings could be relied upon to be identical with those of the human. In order to answer this question scientifically I undertook a microscopic study of several different foramina and adjacent parts in the human being. These investigations corroborate those described in the original work. While no two intervertebral foramina have been found identical, they all appear to have a general structure very similar to the one described. however, the nervous structures in the human being, as a rule, occupy a smaller area of the foramina than is the case in the one shown in the cat. Therefore it would appear they are even *better* protected from bony pressure than is the one from the cat.

2. The Relation of Insurance Companies to Industrial Diseases. F. L. Hoffman.
3. Occupational Diseases as a Public Health Problem. H. Linenthal.
4. Some Fatal Surgical Errors. J. S. Horsely.

1. **The Relation of Industry to General Medicine.**—D. L. Edsall states that a very large part of the bad effects of industry can be controlled only by the employer installing proper preventive apparatus and other measures, but a considerable part of the bad effects can in most cases be prevented by the working people following certain advice, differing with the industry, that can easily be given them when the dangers are known. Also in a great many instances the manufacturers are more or less ignorant of the dangers to which they are subjecting their working people, and when these are pointed out to them are often willing to do a great deal to prevent these dangers.

3. **Occupational Diseases as a Public Health Problem.**—H. Linenthal concludes that diseases due to occupation may be divided into two classes: (1) The specific occupational diseases in which the relation between the disease and the industrial process is a direct one, and (2) those conditions of ill health not specific in character which are brought about by conditions of employment. The latter need further investigation and study. Such studies should be carried on in close co-operation by the hospital clinic, where great numbers of working men and women apply for treatment, and by the governmental authorities who visit the industrial establishments and are familiar with the industrial processes and with the conditions prevailing in the various industries. The specific occupational diseases present no special problem in public health. The methods which have been tried out and found effective by health authorities in the control of infectious diseases are all equally applicable in the control of occupational diseases.

1. Nerve Block and Tuberculosis.—Sir James Grant states that the relationship between nerve tissue and tubercle has long been a subject of inquiry. Sherrington, of Cambridge, and McDonald, of Sheffield, defined the chief constituents of the axis cylinder of nerve tissue as the salts of sodium and potassium which contribute to reflex action and functional nervous activity as a whole. In the treatment of cases of nervous debility and cerebral overstrain, the author has frequently observed sections of the body, particularly the limbs, in which no feeling or sensation was experienced on application of the neurotone charged by a dry electric cell. Suddenly, after several tests by the instrument, sensation developed to a high degree. This abnormal insensibility aroused a suspicion of block in some direction, the sudden disappearance of which led the author to infer that a solution of continuity had taken place in the constituents of the axis cylinder. The problem then presented itself: What change in the axis cylinder constituents interrupted the normal transference of the electric current? Sir Walter Foster, of Cambridge, defined clefts in the axis cylinder but left them entirely unexplained. The most remarkable deduction is that the noxious gases in the alimentary canal, the outcome of imperfect assimilation of food products, not only produce a distended colon, but also result in a chemical change in the saline constituents of the axis cylinder. The author believes that in tuberculosis the chief center of nerve block is in the distended colon, developing slowly and gradually and sapping vitality through a defective blood supply. The author has found that the direct application of the electrical current and massage improve in the above cases the gastric and intestinal digestion, and produce an increased general vitality and a rapid reduction of colonic distention. These are the outcome of the liberation of blocked reflex action and normal nerve power is thus re-established. The object of the application of the neurotone current to the extremities is twofold: to remove all direct nerve block and to arouse increased reflex activity in the terminals of the sciatic and saphenous nerves, which are regarded by the author as accessories to the histogenetic abdominal ganglia and factors in the elaboration of blood, the pabulum of life. Electrical massage should be applied two hours before or after a meal and strictly avoided in all cases of paralysis, for when organic change in nerve structure is in progress electricity is contraindicated.

2. Diseased Conditions of the Cecum.—By G. R. Satterlee. (See MEDICAL RECORD, September 5, 1914, page 440.)

3. Some Features of Pneumococcus Meningitis.—A. Gordon reports a case of this condition in a laborer aged twenty-eight years. There was an absence of cerebral manifestations during life, in spite of the presence of pus; an absence of cranial nerve involvement, in spite of pus at the base of the brain. The development of a tooth abscess preceded the onset of the meningitis. The thinness and viscosity of the pus were highly suggestive in view of the absence of marked cerebral phenomena throughout the disease.

8. Normal Horse Serum in Hemorrhage from Nose and Throat Operations.—By C. F. Theisen and N. K. Fromm. (See MEDICAL RECORD, September 5, 1914, page 441.)

9. Treatment of Ringworm of the Scalp.—P. E. Bechet states that the most valuable local remedies in this condition are iodine (with genuine goose grease as a base it is very efficient particularly in the early cases), and mercury in the form of ammoniated mercury up to ten per cent. strength, or oleate of mercury in ten to twenty-five per cent. ointment. Chrysarobin, in saturated solution in chloroform, painted on, and after evaporation of the chloroform, covered with several layers of collodion, is particularly useful in the chronic cases. Sulphur in twenty per cent. ointment with ten per cent. naphthol, is very useful. An ointment which is frequently used at the New York Skin and Cancer Hospital with good results when the parents are sufficiently impressed with the necessity of vigorous application, consists of red oxide of mercury ointment, a dram and a half; sulphur ointment, three drams; cold cream, one ounce. Needling as recommended by Aldersmith should be reserved for the more stubborn cases, as it is rather a severe measure depending on an inflammatory reaction and the formation of a kerion for its success. In the absence of inflammation one cannot be too vigorous in the application of any of the parasiticide ointments. This really constitutes the key to a successful result, a fact easily understood when one considers the location of the fungus.

1. Pituitary Disorders.—Harvey Cushing reviews the disturbing symptoms produced by these disorders when accompanied by an extreme glandular enlargement or when the secretory activity of the gland is embarrassed. These are essentially of a mechanical nature. The constitutional symptoms may not correspond with the size of the growth. The subject is rendered still more complex when one attempts to differentiate between the two lobes of the gland which have quite different functions. Another cause of complexity is the polyglandular nature of every gland disorder which in some cases may cause doubt as to which of the endosecretory organs was first at fault. The view now prevalent is that any derangement of the correlated glands excites disturbances in the others but with the qualification that the primary

disorder of any individual gland, either of oversecretion or undersecretion, causes its own peculiar group of symptoms. The insufficiencies of adrenal, parathyroid, and pineal glands, of the islets of the pancreas and the cells of the sexual organs give rise to their peculiar syndromes, and while one knows little of the reverse conditions, except in the thyroid and anterior lobe of the pituitary, the recognition of primary overaction of the other glands will doubtless be forthcoming. It now appears that functional hyperplasia of the anterior lobe stimulates tissue growth, especially of the bones and integument, and at the same time excites the reproductive apparatus as shown by the secondary characters of sex. Little is known, however, of the functional hyperplasia of the posterior lobe, which seems to be more concerned with tissue metabolism, for when rendered inactive by disease or compression, metabolic processes are checked and the symptoms produced somewhat suggest the phenomena of hibernation. The tendency toward a relative glandular inactivity seems to occur in most cases of pituitary disease, and commonly symptoms of glandular insufficiency come in time to be superimposed on those of outspoken acromegaly. The term dyspituitarism is used to designate all types, though in some cases hypopituitarism appears from the start. Many obscure symptoms, such as certain forms of obesity and leanness, polyurias, etc., undue drowsiness, delayed or precocious puberty, have been shown to be due to disturbances of the pituitary secretion. Promising results have followed glandular therapy and surgical procedures, and have been indicated in some cases to relieve pressure symptoms, etc. The author presents an analysis of 148 cases, 101 of which presented definite tumor symptoms and skeletal changes, and forty-seven of which lacked these local signs of the disease. Cases of abnormal sellas with hypopituitary symptoms need only glandular and not surgical treatment. The author's experience has not been especially happy with the lateral subtemporal route of Horsley or the frontal approach advocated by Hartley, Krause, and McArthur, though he has had but few operations as yet in which either was employed in cases in which there was no great deformity of the sella. The operations for tumors distending the sellar fossa have been much more encouraging, and the procedure the author has come to employ is a modification of the Schloffer operation, suggested by Kauffman, Hirsch, and others, and adapted to the author's own requirements. The operation combines all the advantages of the endonasal precedure of Hirsch, and affords almost double the room that operating through the nostril affords. In many of the author's cases a simple decompression was employed; in four cases on both sides, and in a number multiple operations were performed, such as the transphenoidal operation or sellar or subtemporal decompression.

2. **Closure of the Pylorus for Pyloric and Duodenal Ulcer.**—A. A. Strauss states that in sixteen dogs operated on by the submucous transplant method, the pylorus was water-tight under hydrostatic pressure and as shown by fluoroscope and roentgenogram. The free fascial transplant became organized with the mucosa and muscularis in every instance, producing sufficient contraction to hold the pylorus closed without producing any necrosis of mucosa. This the author believes is due to the fact that the connective tissue used is placed under a tension similar to what it would be in the anterior sheath of the rectus. The free transplant placed between the mucosa and muscularis has the advantage of not having overcome the powerful peristaltic contractions of the pyloric musculature, and is not subject to the formation of adhesions and inflammatory changes, as a transplant placed around the musculature of the pylorus would be. The method of shelling out the mucosa is safe, in that there is no danger of hemorrhage from large vessels, and less danger from infection, as in the methods by which the mucosa has to be divided. The silk-ribbon method, while it is very simple and produces a perfect closure, and while the number of experiments seem to show it to be a fairly safe method, has the objection of having a large foreign body buried. Of the two methods the transplant method is by far the one of choice. The rubber method the author considers dangerous and a failure.

4. **Studies in Liver Function.**—By A. M. Chesney, E. K. Marshall, Jr., and L. G. Rowntree. (See MEDICAL RECORD, June 27, 1914, page 1190.)

5. **A Typhoid Carrier at a Public Dinner.**—W. A. Sawyer has traced the source of infection in ninety-three cases of typhoid fever in an epidemic at Hanford, Cal., to a typhoid carrier who prepared food served at a public dinner. The vehicle of infection was a large pan of Spanish spaghetti prepared by the carrier. This dish was baked after it had been infected, but this baking was shown by laboratory experiments to have incubated the bacteria instead of sterilizing the food. Certain customary methods of cooking are thus shown to be inadequate as a protection against infection. The incubation period in the majority of the cases in this epidemic of typhoid fever proved to be shorter than the time usually regarded as the minimum. The first case developed three days after infection. More cases showed their first definite symptoms six days after the infected food was eaten than on any other one day. The ways in which a carrier may transmit infection are so varied and so numerous that attempts at the control of mere channels of infection will not offer sufficient protection. Those who were suspicious of the raw salad at the dinner in Hanford and ate the freshly baked spaghetti turned from a safe dish to one which was heavily infected. The best protection against carriers will come through thorough investigation of the source of infection in every case of typhoid fever. When carriers are discovered they can be advised and controlled. The writer warns us that until we have a sufficiently large number of properly trained epidemiologists on a full-time basis among State and local health officials the danger from carriers will not be noticeably diminished, and the individual will find in antityphoid vaccination his best protection against infection from carriers.

6. **Blood Transfusion by the Syringe Cannula System.**—By E. Lindeman. (See MEDICAL RECORD, July 4, 1914, page 37.)

11. **Late Manifestations of Inherited Syphilis.**—By H. F. Stoll. (See MEDICAL RECORD, July 4, 1914, page 36.)

13. **A New Method of Reflex Elicitation.**—W. B. Swift concludes that the examination of over forty types of reflexes during and some after the passage of the electric current demonstrates that the general effect of electricity on the reflexes is that of a reinforcement which finds its special clinical value by elicitation of some of the absent reflexes unobtainable by any other method. The author therefore claims a new method of reflex reinforcement of sufficient value to be included among other routine and neurological examination methods in the following order: Pendulum leg, diversion of mental attention, constant movement during stimulus, the Jendrassik hand-grasp, and finally, when all other of the above-mentioned methods fail, the electrical reinforcement.

6. Epsom and Ewell War Hospital. E. Owen.

3. Pyloric Obstruction in Infants.—C. H. Miller notes that this condition is more common in males. The symptoms commonly begin in the second month, and consist of forcible vomiting, visible gastric peristalsis, wasting, and constipation. As to the presence of a palpable pyloric tumor the author is rather sceptical. He has felt a hard cylindrical tumor in certain cases, especially during gastric peristalsis. But it is impossible to palpate deeply in many cases, and in some cases of wasting with a lax abdominal wall the author has felt a similar tumor. He regards the palpability of the pylorus rather as a sign of wasting than of pyloric hypertrophy. The medical treatment consists in (1) keeping the patient warm; (2) washing out the stomach, and (3) feeding with predigested milk. Drugs are occasionally useful. When there are much colicky writhing and abdominal tenderness the author gives tincture of opium, ¼ minim three times a day for two or three days. He has tried belladonna, but found it useless in this disease. The bowels must be kept open: an occasional dose of castor oil followed by gray powder will often be sufficient. Phenolphthalein is perhaps the most satisfactory drug to use regularly. In the very bad cases medical treatment only can be recommended. When such patients begin to improve and are strong enough to stand an operation a surgeon might give his opinion once more. If the condition remains stationary for long or begins to decline after an initial improvement a surgeon should be called in.

4. Prognosis in Cancer of the Tongue.—W. Trotter states that operations undertaken for epithelioma in which the diffuse stage has begun are particularly apt to be followed by early, rapidly growing, and diffuse recurrence even when the type of disease has been recognized, the growth is quite small, and the excision has been very extensive. It cannot be doubted, therefore, that in these cases there is a diffusion of cancer cells throughout the tissues around the growth to a distance far beyond the palpable induration and extending into regions which do not display the least abnormality to the naked eye. When, therefore, operations are undertaken for this type of the disease there is no chance of cure unless an extremely drastic procedure is adopted. A radicle extirpation of the tongue muscles down to and perhaps including the great cornu and body of the hyoid bone at the least on the affected side is essential, and there is a good deal to be said for total extirpation of the tongue and hyoid bone. The only serious dangers of even the most extensive operations are those due to sepsis, which takes two forms—infection of the lungs and infections of the wound. The former if at all severe leads to abscess formation and gangrene with an almost necessarily fatal result; the latter may lead to acute septicemia or to a cellulitis extending diffusely in the neck, with the risk of mediastinitis and of secondary hemorrhage. The best precaution, therefore, against lung infection is the abolition of the possibility of aspiration. Local infection can usually be prevented by adequate suture of the wound. Patients with clean mouths and who are habitually careful with them are little if at all less liable to serious complications than those who are careless and whose mouths are obviously septic. Edentulous patients give rise to no serious anxiety on the score of sepsis.

1. Enforced Dogmatism in Medicine.—Sir Frederick Treves shows how a great deal of the science of medicine of the past was founded upon pure nonsense, or rather upon the fables evolved to satisfy the demand of the public for dogmatism in all that related to ill health. In this extraordinary product the physician himself believed. The tale had come to be accepted as true; it was a matter of sober study; it formed the basis of the education of every medical man, while its ridiculous gibberish became the speech of the cultured physician. The true science of medicine, the science based upon assured facts, was proceeding side by side with this phantasm, but its influence was slight and its movement almost imperceptible. The course of medical progress had been diverted from the firm road into a shaking quagmire, where men stumbled to and fro, talking, so far as the ears of truth were concerned, in unknown tongues. The people insisted upon a complete, infallible system of medicine where there was neither doubt nor wavering, and they obtained in response to their impossible demand a fabric of fiction which is unique in history by reason of its magnitude, its detail, its audacity, and the completeness with which it satisfied the demand that called it into existence. This vast work of invention had no more concern with the living science of medicine than has the cocoon with the living butterfly. It was the people who were the leaders of early medicine. That they led it utterly astray does not alter the fact that they led. The physician had to adapt what little he knew or professed to know to the attitude of mind they displayed. The channels available for the expansion of medicine were channels directed by the people's needs and expectations, while the very details of the art had to conform to the popular understanding. The whole of this spurious science has long been swept away. Medicine is now an exact science founded upon well-tested facts; its speculations are directed by reasons and justified by experience. While its confines have been enormously extended, while its ramifications have become almost bewildering and its potentialities amazing to contemplate, its principles have been consolidated, simplified, and reduced to a few great propositions.

3. The Soldiers' Footgear.—C. Webb-Johnson insists upon the following details in fitting a soldier with boots: (1) Fit the boot after a march, when the foot is fatigued and swollen. (2) Fit the boot over the thickest sock. (3) Have both boots properly laced, to see that the quarters are not too high and that the ankle-joint is free. (4) Fit each boot separately. (5) Make the soldier stand and walk in his boots before deciding which pair to give him. (6) If no ready-made pair fit, insist upon a special pair being made. (7) Give full instructions about the preparation and subsequent care of the boots. (8) Give a boot that is too large rather than one that is too small, for leather when wet shrinks.

On handing a recruit a new pair of boots he should be told to soften them before wearing them, and this is best done by well soaking them inside and outside with crude castor oil. It is important to keep the uppers supple by the constant use of oil or dubbing, and this is especially necessary when the boot is thoroughly wet. If this is not done regularly the leather becomes hard and brittle, and one of the commonest mistakes a soldier makes is to place his wet boots near a fire. It is on record that during the first winter in the Crimean war the British soldiers suffered from their boots getting soaked through and many were in the trenches without either boots or socks, as the leather of the boots shrank so much from the constant wetting that when once they were taken off it was impossible to get them on again. In the Balkan war the result of men being in the wet trenches for from twelve to twenty-four hours was seen in various forms. Many suffered from cholera and dysentery, but it is also stated that gangrene of the foot was not an uncommon occurrence, beginning in a painless way with mere discolored blistering over one or two toes, to death en masse of the leg as high as the knee. Depage considers that many of these cases were caused by the pressure of damp boots and putties shrinking as they dried. It is probable that a vasomotor disturbance very similar to this occurred in the Crimean war and was classified in the statistics as frostbite.

Berliner klinische Wochenschrift.

September 28, 1914.

Military Sanitary Service in Berlin.—Under this general heading Brettner begins a series of articles which had their counterpart during the Franco-Prussian war in the columns of the *Wochenschrift*. The activities of a single improvised military reserve hospital of 149 beds are given. On August 24 the wounded began to arrive, apparently from a garrison hospital, to the number of 128, the wounds having been received three days earlier. The nurses were untrained artisans who had been rejected for military service, and these received daily instruction at the bedside. The physicians in charge of reserve hospitals are chiefly civil practitioners who receive a stipend of 15 marke daily, and each must assume charge of from 60 to 80 beds. In most patients treated the wounds, whether from bullets or shells, were slight, healing in some ten days, and the recovered were at once sent back to the front. Wound infection was practically non-existent. The men were from the first able to talk over their experiences in the trenches, and when leaving the latter—during which period no shelter was too insignificant to be utilized. If wounded at night they hid in cellars or elsewhere until they could come forth in safety. Since these wounded were able to enjoy life they were well supplied with games and reading matter. They were furnished with baths, cigars, wines, delicacies—even caviare—and fruits, and regaled with music. From this article it readily appears that, contrary to the popular impression, reserve hospitals are designed largely for the slightly wounded, for these alone could stand the protracted transportation, and here also convalescence can be accelerated.

Present Status of Bloodvessel Surgery.—Jeger completes a serial article on this subject and after the discussion of vascular anastomoses of all kinds and the transplantation of organs which depend on proper vascular suture technique, he proceeds to discuss some of the more striking forms of surgical intervention in this province. Under the head of arteriotomy for the removal of emboli he cites the remarkable case of Bauer, who successfully removed one from the abdominal aorta. In regard to removal of emboli from the pulmonary artery (Trendelenburg) there has been one technical success, death having been due to an independent cause. Various improvements in technique will doubtless tend to make the prognosis of this intervention more favorable—for example, compression of the vena cava to render the artery empty. Under the head of aneurysm Halsted's operation of incomplete arterial constriction is mentioned. German surgeons are using a clamp to produce the same result. The work of American surgeons on suture of the thoracic duct is mentioned. A form of intrinsic transfusion is mentioned in which the blood stream in a smaller artery is infused into a larger vessel by means of a catheter. Bleichroder and Unger, the pioneers in this province, have diverted the femoral circulation back into the aorta, and thus have secured anemia of the limb concerned. Another intervention still in its infancy is the establishment of an Eck's fistula in man in cases of portal obstruction. While the typical operation has not thus far proved much of a success the outlook is better when two smaller vessels are concerned, as the splenic vein representing the portal and the renal vein the systemic circulation, and venous anastomosis between the superior mesenteric and ovarian vessels. In the surgery of aneurysms of the sacculated type the ideal is ablation of the sac and restoration of continuity in the blood vessel, if necessary by plastic substitution. Many surgeons are engaged on this problem and much experimental work has been done. The author, Matas, and others have obtained encouraging results, and since in aortic aneurysms it is not necessary either to sacrifice wholly the sac or to restore the exact caliber of the vessel, the principles which underlie Matas' successful operation for fusiform aneurysm may come eventually to prevail in the sacculated type.

Münchener medizinische Wochenschrift.

September ??, 1914.

Resorption Fever or Retention Fever.—Hamm claims that the old doctrines of sapremia and putrid intoxication are founded on the belief that the germs in the genital passages do not themselves enter the blood and cause metastases. As soon as this occurs we have to do not with simple intoxication but with superadded infection. In so-called states of intoxication there may be free drainage of the decomposed material from the genitals, which naturally complicates the situation. The source of the toxemia may in theory be the cleavage products of the putrefying debris of the fetal appendages or the secretions of the saprophytes which cause or at least hasten the decomposition. Many recent observers and experimenters have shown that the saprophytes can enter the blood and even cause pyemic abscesses. They are therefore not confined to dead tissue for nutriment. In other words, no absolute distinction can be made between saprophytes and pathogenics, nor between sapremia and sepsis. The pathogenic may behave as a saprophyte and *vice versa*, although as a rule the rôles are not interchangeable. All of this more recent teaching is itself old to-day because it has not been tested by the developments of the past ten years. For example, until recently anaphylaxis has not been investigated in connection with this problem. It is now claimed that the saprophyte can cause anaphylaxis and that in all probability the normal lochia may contain an anaphylatoxin in great quantities, in which case the latter would certainly occur in infected lochia, decomposed embryonal residues, etc. This leaves unconsidered the bacterial endotoxins which are not the same as the anaphylatoxins, but the author believes that the evi-

dence is against the occurrence of endotoxin absorption, and even of its formation—for from all we know at present bacterial endotoxins do not form save in living tissues. To demonstrate absorption of anaphylatoxin is a difficult matter and experiment makes it seem probable that when this phenomenon does occur the puerperal vagina may be the site of absorption. Leaving this aspect of the problem as unsolved the author returns to the old subject of putrid intoxication and claims that since it cannot occur when puerperal drainage is perfect any fever in childbirth not necessarily septic should simply be termed retention fever; for this word at once supplies us with an indication for treatment.

Pathology of Paratyphus Abdominalis.—Glaser shows as a result of carefully conducted autopsies on cases of typhoid sufficiently controlled bacteriologically and serologically during life that the distinction between fully developed typhoid and fully developed paratyphoid is academic. The parallelism is complete in all but the counts just mentioned. In one case of paratyphus the number of intestinal ulcers was strikingly large and involved not only the lower small bowel but the entire colon. The paratyphoid stools had all the appearance and odor of typical typhoid dejections, while a typical roseola was present. The diazoreaction was positive. Although the author controlled but two cases of paratyphus the relatively mild character of the latter as a clinical phenomenon and the comparative infrequency of autopsy material should not obscure the fact that there is a form of the disease every whit as deadly as true typhoid, from which it cannot be distinguished save by blood and bacteriological finds. The choleriform type of paratyphoid disease may also be very deadly.

Treatment of Intestinal Prolapse in the Field.—Riedinger states that the present European war should determine finally to what extent if any primary laparotomy should be undertaken in the dressing stations. After mentioning the circumstances under which the intestines protrude through abdominal wounds the author states that in the great majority of cases reposition is readily effected. When, however, this is very difficult or impossible the opening must be enlarged so that virtually laparotomy is performed. By using retractors and perhaps ablating some of the prolapsed omentum, the patient being in Trendelenburg's position, reposition may be effected without enlarging the wound. Naturally, injured intestines must be treated before reposition can take place. At the moment when the wound is dilated with retractors the peritoneal cavity should be inspected. If the prolapsed intestine is crushed at any point the afferent and efferent gut is ligated and fastened and the patient sent to the field hospital for immediate operation. All abdominal wounds must be dressed with a compress of gauze fastened with plaster and a roller for transportation.

September 24, 1914.

Psychiatry and War.—Bonhoeffer states that psychoses appear among troops, who are naturally believed to be picked men, and that the presence of these subjects in the ranks tends to disturb discipline. During the few weeks of warfare in Germany psychic disorders have been manifested in the field. A debile who had become disoriented in battle began to fire upon his comrades from a church. A vice sergeant major repeatedly disobeyed orders and finally lost his command. At court martial it was found that he was a paretic. A third officer, clearly in the twilight state, left his command and started home. Other cases are to be expected among the personnel of the medical service, for in the case of the wounded the attendants may become excited and some of them develop acute psychoses. Such men should be weeded out in advance, or as soon as they become excited. Much may be done while organizing commands and during musters in eliminating all subjects of psychopathic constitution; for these are likely to give way under severe discipline, forced march, etc., to say nothing of actual fighting. These men may pass successfully the ordinary physical examination, and there should be ways of isolating suspects. Any history of a psychosis should reject unqualifiedly, despite the present state. "War affects" are naturally the most powerful known, and the soundest minds are not proof against them. "Persistent affect tension" is combined with overexertion in campaigns; crazes like "spy fear" and fear inspired by rumors exist. It is not surprising that the psychopathic constitution is not proof against the strain and that the non-combatant suffers as much as the soldier. In regard to the nature of the psychotic outbreaks none of the latter are actually peculiar to soldiers. We see chiefly hysterical seizures, fainting fits, functional abasia—these follow a glimpse of the transport of wounded, etc.—phobias, hysterical vomiting, insomnia, twilight states. In the debile and epileptic we see affect and impulsive behavior. At a later period we see phenomena suggestive of exhaustion—apathy, prostration, depression, insomnia and hallucinations, especially of the senses, and worse at night. The subject hears imaginary shells burst, smells imaginary carrion. Quite striking is the hyperesthesia of many soldiers who jump at the slightest touch. Alcoholic abstinence delirium is seen chiefly among the older troops whom the first mobilization has deprived of the daily spirits. War probably inaugurates and certainly accelerates the development of paresis and dementia precox, while its relationship, if any, to manic depressive insanity has not been determined. The psychotic in war must first be isolated from his fellows and quieted with morphine-scopolamine preparatory to removal to some special destination. The affection may in the meantime be shown to be transitory, but under no condition is the subject to rejoin his company.

War Ophthalmology.—Axenfeld of Freiburg discusses the subject of the wounded who were foredoomed to arrive from the Alsatian battlefields so near at hand. The eye may be injured in a great variety of ways, direct traumatism counting as but one. Bullets which strike the throat, for example, may find lodgment in the orbit. The question of preventing sympathetic ophthalmia is all important, as is also in case of extirpation the securing of a proper stump for an artificial eye. In destruction of the eyeball, with hopeless blinding, the bulbus must be exenterated with the curette, while the eyelids are temporarily sutured until at some future time blepharoplasty becomes possible. Certain wounds of the bulb when seen at an early period may be successfully closed by ophthalmic surgeons of great technical skill, some plastic work often being involved. Small foreign bodies in the globules, as well as various injuries received in hand to hand fighting, help to make up the quota of ocular traumatisms. The enormous air pressure following explosion of shells has been known to cause intraocular hemorrhages with blindness. In any suspicion of foreign bodies an expert examination must be made with the *x*-ray and magnet needle. The author closes by hoping that in the future ophthalmic surgeons will be supplied for the field hospitals, for when the injured reach the reserve hospitals it is often too late to save sight.

Insurance Medicine.

Causes Influencing Mortality.—Weyth E. Ray, Medical Director Germania Life Insurance Company, says that insurance mortality results are of necessity primarily affected by medical selection. The personnel of the insurance force is largely a controlling factor. No better medical examiner was ever found than an honest agent; he makes a better examiner than a dishonest medical examiner. Ray considers that medical examiners should be appointed by the medical department, absolutely without any recommendation on the part of the agents. Honesty and integrity, with a fitness for the position, should be the greatest requirements. Then the force below should be backed up and thoroughly supported by the medical director. On the other hand, too critical a staff only embarrasses business. These conditions satisfied, it would seem an important matter to have the company decide what it wants to do. Some companies want a very low mortality, others do not, there being one feature of life insurance that is at times overlooked, namely, the philanthropic side. Too low a mortality is often a criticism on the medical selection, and puts the company in the position of business for profit rather than the protection of human life. What is to be desired is a mortality that is not too high, but high enough to furnish the business moderate protection. It does not do to select nothing but first-class risks. The result is the applicant who is denied becomes angry, also his friends, the premium is lost, together with the interest on it, the agent may resign and new business be lost, and the ratio of mortality goes up rather than down. It is wiser to select as carefully as possible and still maintain the ordinary mortality. In considering the question of new business it is certain that the larger volume of new business the lower will be the mortality, independent of selection. The section of the country from which business is received must be considered. Certain sections have a higher mortality than others. About four years ago it was noted that a very peculiar factor was at work in this country. If taken by states over the United States and a graphic table made indicating the lowest tax state on up to the highest tax state, it was found that where the state tax was the lowest there was the lowest mortality, and where the highest mortality was found the tax was the highest. In other words, the state was being paid for the honor of losing money. The type of policy is to be considered. If a company has the right type of policy, the lower the premium average the higher the mortality, ordinarily. Thus the company which has a large amount of term insurance, a large percentage of ordinary life, will have a higher mortality. In certain sections there exists a greater preponderance of these last-named policies as compared with twenty-payment life and endowment; there it will be found that the mortality will be higher ordinarily than in other sections. A higher average premium is needed. Not the size of the policy: the greater the size the higher the mortality, dependent upon self-selection against the company. The influence of age is very important. The company showing acceptance of risks beyond the average age will have a higher mortality. At forty-eight the mortality is lower than we have built our premiums upon, while after fifty it is considerably higher. After forty-five or fifty, selections must be made more carefully. The lapse ratio will also affect the mortality. The manner of acceptance of new business has great weight. Cases must be divided into two classes—decreasing and increasing hazard. Every single policy in use to-day, whether single premium, ten-year life, twenty-year endowment, is built upon one factor—100 per cent. mortality. That is the basis, and how is it possible to make it cover 125 or 150 per cent. each year? It has been pointed out by different men that twenty-year endowment and ordinary life is a terminable feature worth 12½ per cent., from the standpoint of mortality. Ray believes that no matter what the form of insurance, there must be extra premium if you are going to charge premium enough, that this extra premium must be charged on ordinary life, not endowment. However, as far as the medical man is concerned, it should make no difference what the policy desired by the applicant, but "what shall this man's mortality be?" It is not the medical man's affair to recommend to the company the type of policy to be issued to any certain applicant, but to simply write "125 per cent," or whatever it may be.—American Life Convention, March, 1914.

Medical Life Insurance.—Last spring the executive body of the State Medical Association of Texas established the Section on Medical Life Insurance. Dr. J. H. Florence, Houston, Texas, Chairman of the Section, in his inaugural address held that large benefits will accrue to the medical profession as a result of its cooperation with life insurance companies, judging from the fact that last year the insurance companies of the United States paid to the profession approximately six million dollars for services rendered. To-day there are twenty-four Texas companies with insurance in force representing the huge sum of one hundred and seventy million dollars, and it is estimated that not over 10 per cent. of the insurable people in that State carry policies. Such a combination of forces tends to promote public welfare.

Life insurance companies are more and more studying the conditions promoting public health. Many companies have established at their own expense bureaus or departments of public health for the benefit of their policyholders. The idea that this is from purely selfish motives will probably intrude itself upon our minds; whatever the motive we must admit the results will be eminently beneficial and far reaching. The profit to a company must accrue greatly from the saving in mortality. Realizing that the greatest efforts to guard the lives of the insured will be to our interest, every effort should be made to protect these lives from disease and death. In the East, the "Life Extension Institute" was established in December, 1913. Its efforts are directed not only to the benefit of life insurance companies, but still more so to the welfare of mankind in general, by the lengthening of human life through the application of modern science. While the death rate of preventable diseases is on the wane, diseases of the kidneys and of the circulatory and nervous systems are on the increase. These facts offer more reasons why any successful cooperation should be viewed with favor and bring lasting results.—*Texas State Journal of Medicine*, July, 1914.

Book Reviews.

ABDOMINAL SURGERY. CLINICAL LECTURES FOR STUDENTS AND PHYSICIANS. By THORKILD ROVSING, Professor of Clinical Surgery at the University of Copenhagen. Edited by PAUL MONROE PILCHER, A.M., M.D., Brooklyn, N. Y. With 136 illustrations and 9 plates. Price, $5.00. Philadelphia and London: J. B. Lippincott Company, 1914.

IT is with mingled feelings of pleasure and disappointment that we comment upon this book. We feel grateful to the editor who has enabled us to appreciate the charm of a personal visit to Rovsing's clinics; for the translation is so perfect, the style so easy and graceful, that one can readily imagine one's self actually in the presence of this eminent surgeon and teacher. These are clinical lectures, but there is nothing stilted, nothing pedantic about them. One criticism, however, seems apropos at this point. One is unconsciously annoyed by the habitual use of Latin terms and phrases—quite correctly, it is true—without the definite or indefinite article: *e.g.* "holds colon transversum," for holds the transverse colon. Nothing is gained by retaining certain Latin terms and phrases when all the rest is translated.

The first real disappointment came with the realization that none of the lectures is devoted to the subject of renal surgery, a field in which Rovsing has done such magnificent work; but that instead the first quarter of the book is devoted to elementary subjects, including the history and development of antisepsis and anesthesia. Our next disappointment came when we found that but a very limited portion of abdominal surgery is covered by the lectures. What we expected in a book such as this purports to be, according to the title, was Rovsing's ideas as to the interpretation of symptoms, methods of diagnosis, including differential diagnosis, the indications for and methods of operating in a series of conditions affecting all, or at least most, of the various abdominal organs; but we find merely incidental references to diseases of the intestines, appendix, gall-bladder, kidney, pancreas, and other organs except the esophagus, stomach, duodenum, and liver, the lectures in the latter case being limited to a discussion of echinococcus cyst and abscess of the liver, with a short lecture on jaundice. About one-half of the book is concerned with gastroptosis and ulcer of the stomach and duodenum. These subjects are considered from every angle. The lectures are usually based upon actual clinical cases and the steps in the diagnosis and differential diagnosis are brought out in a most interesting and instructive way.

It is interesting to note that Rovsing finds an unusually large field for surgery in gastroptosis and seems to have had remarkable success in the treatment of this condition; that he is a rabid partisan of the anterior method of performing gastroenterostomy; that he believes that most cases of hour-glass stomach are the result of sagging of its central portion with subsequent adhesion of the opposed peritoneal surfaces, and that ulcer forms secondarily upon the exposed ridge projecting into the lumen of the stomach; that in cases of gastric ulcer excision, when possible, is the best method; and that gastroenterostomy is disappointing, as a rule, except where there is obstruction.

The book is full of practical suggestions, many distinctly original, and cannot fail to interest the internist as well as the operating surgeon. We may be permitted to express the hope that another series of lectures devoted to the other abdominal organs may soon be made available through the cooperation of Rovsing and the editor who has done his work so well in the present instance.

A REFERENCE HANDBOOK OF THE MEDICAL SCIENCES, Embracing the Entire Range of Scientific and Practical Medicine and Allied Science. By various writers. Third edition completely revised and rewritten. Edited by THOMAS LATHROP STEDMAN, A.M., M.D. Complete in eight volumes. Volume Four. Illustrated by numerous chromolithographs and 977 halftone and wood engravings. Price, $9.00 net; half-morocco. New York: William Wood and Company. 1914.

SOCIAL medicine, medical biography, and the newer developments of biological study in relation to human problems all come in for a goodly share of attention in this volume, not to mention the topics that concern the everyday work of the practitioner. Among the longer articles may be mentioned those on epilepsy, enteroclysis, esophagoscopy and gastroscopy, the surgery of the esophagus, medical ethics, medical ethnology, eugenics, euthenics, evolution, excisions, the anatomy of the eye, the dioptries of the eye, injuries of the eye, tumors of the eye, enucleation and evisceration of the eyeball, eyestrain, medical fees, development of the fetus, food and drug control laws, food poisons, foods for the sick, disabilities of the foot, distortions of the foot, fractures, fungi, diseases of the gall-bladder and gall-ducts, the genital organs, gestation, ectopic gestation, gigantism, exophthalmic goiter, growth, gunshot wounds, gynecological examinations, the hand, diseases and deformities of the hands and fingers, and hay fever. The bibliographical references include works and articles published during the present year. The article on Evolution presents this subject in the light of the most recent researches, particularly as to the inheritance of acquired characters, the application of the principles of Mendelian heredity, and the statistical studies of Pearson and others. There is an interesting exposition of Eugenics by Charles B. Davenport. The distinction is made between "hygienic" and "eugenic" marriages, and a program for the state control of marriages is outlined. It is proposed that for those who violate governmental prohibition by bringing a child into the world the penalty should be sterilization of the male. But why penalize the male alone? This one-sided provision would at any rate have no biological justification if the female is insane or is capable of transmitting insanity and if her male partner is not only normal but belongs to an untainted stock. Medical ethics are discussed in a witty and unconventional manner by Abraham Jacobi, who shows that the "gentleman" in medicine has little need of ethical precepts which, however, may guide the inexperienced in an era of close competition. A large number of interesting data appear in the article on Medical Ethnology by Colonel Charles E. Woodruff. Individuals of the brunette "persuasion" may possibly derive comfort from the fact that in New York "the blondes furnish an undue number of paupers, insane, and chronic offenders against property." The articles on the eye comprise a series of 80 pages, that on Excisions takes up 47 pages, and that on Fractures is fully covered within the limits of 44 pages. Royal Whitman contributes eminently practical articles on the disabilities and distortions of the foot. Another series of regional topics which seem to be a conspicuous feature of the Reference Handbook, are the articles on the Hand. Frank Baker deals with the hand in folklore and superstition, paleontology, embryology, anatomy, and physical expression (the so-called "physiognomy of the hand") and discusses the various theories as to the origin of right-handedness. The articles on the Diseases and Deformities of the Hands and Fingers, originally written by J. B. Nicholls, has been revised and enlarged by Leonard W. Ely. Among the different types of hand illustrated in the numerous drawings may be mentioned the "preacher's hand" of hypertrophic cervical pachymeningitis, the "ape hand" of progressive muscular atrophy, and the "claw hand" of ulnar paralysis or of progressive muscular atrophy. The hand of the baseball player typifies an occupational deformity. An interesting diversion for the medical reader would be afforded by the systematic perusal of the large number of short biographical sketches which are scattered throughout this volume, and which in many instances are embellished with portraits. Of particularly timely importance is the article of 47 pages on Gunshot Injuries by Colonel Louis A. La Garde. The short articles on health resorts contain information which the physician is wont to seek, namely mode of access, climate, analysis of springs, and therapeutic properties. The volume is superbly illustrated with halftone and wood engravings, including colored plates on esophagoscopic views, mushrooms, and gangrene.

LES ANOMALIES DE L'URINE; leur Recherche simplifiée et leur Signification. Par A. ESCAICH, Pharmacien de 1re Classe. Price, 3 francs. Paris: Vigot Fréres, 1914.

THE principal characteristic of this book is the simplicity of the qualitative and quantitative researches given in it. It contains all that refers to the chemistry, physiology, and pathology of urine in a condensed form. An alphabetic index will facilitate the diagnostic difficulties of physicians and pharmacists.

Section on Surgery.

Stated Meeting, Held October 2, 1914.

Dr. C. A. McWilliams in the Chair.

A Case of Thromboangiitis, Whose Wassermann Was for a Long Time Negative but Is Now Positive.—Dr. William C. Lusk reported this case. (See page 833.)

Thromboangiitis Obliterans, Ulcer of Toe.—Dr. Frederick Theodore van Beuren, Jr., presented this patient, a Russian Jew, 30 years of age. He was admitted on July 7, 1914, to the service of Dr. Hotchkiss, Roosevelt Hospital. Some time during the past winter he froze his left great toe, but thought nothing of it at the time. Three months before admission he noticed a little crack on this great toe which he picked open with his finger nail. Since that time he had had pain in the toe and the crack had become a large sore. The pain had been continuous, worse at night, aggravated by raising the leg horizontally, and slightly alleviated by hanging it down. When he lay down and straightened out his legs, he felt throbbing behind the knees. For the previous three months, he said, he had been able to sleep only with his left leg over the edge of the bed. He had to quit work because he could not stand for any length of time without pain and he could not walk more than a block or two without severe pain in the calf. He denied any venereal infection; he drank a little beer; he never smoked more than ten cigarettes a day. His family history was negative. He appeared well nourished and in good physical condition, but he walked with a limp and his face showed an expression of pain and anxiety. His gums exhibited marked pyorrhea alveolaris. His superficial inguinal glands were readily palpable. The left leg was slightly edematous from the knee downwards. All the toes and adjacent metacarpal region were a purplish red color, but not cold and tender except for the great toe which was moderately swollen and extremely tender in the region of the superficial indolent ulcer, 1.5 cm. in diameter; this had a sloughy base and rather calloused margin and occupied the mesial aspect of the base of the proximal phalanx. Pulsation could be felt in the posterior tibial artery at the ankle joint, but not in the dorsalis pedis artery. His urine was normal. The Wassermann reaction was negative. During the first six days in the hospital he was kept in bed and his leg and foot baked one hour every day. He had so much pain, however, that he begged to be allowed to sit in a chair. His discomfort was so great and other treatment had proven so unavailing that it seemed justifiable to try femoral ligation for impeding the return circulation, a method suggested by Hesse and Oppel and as carried out by Lilienthal; the latter had reported last winter four cases with marked alleviation of the pain in three. On July 14 a 3½ inch vertical incision in the left groin gave easy access to the vessels and the femoral vein was occluded by chromic gut sutures. On removing the covering of the leg at the end of the operation moderate duskiness of the extremity below the knee was noted. One and a half hours later the edema and duskiness of the toes were slightly accentuated. The next day he had moderate pain in the toe and there was a bleb, 1 cm. by 3 cm., noted on the dorsum of the foot (possibly due to the external heat), but the duskiness of the leg had nearly disappeared and the circulation of the toes which was still pretty red returned fairly rapidly when pressed out. For the next ten days progress was favorable and he had no further pain; the edema of the leg and foot almost entirely disappeared and the toes were much less red. Tenderness around the ulcer disappeared, but the ulcer did not heal. On the twelfth day after the operation pain in the foot returned. July 30 he left the hospital; the swelling of the foot had returned; the ulcer of the toe had slightly lessened in size, and the bleb on the dorsum of the foot had broken, leaving thin epithelium exposed. The patient said that he felt better than before the operation. During August he was treated by baking and massage; at first he suffered considerable pain, but after a couple of weeks he began to notice a slight but distinct lessening of the pain. This improvement had continued and during the past few weeks he had again been able to sleep with the leg in the horizontal position and he could walk more than one-quarter of a mile without pain and his outlook upon life had become more cheerful. Inasmuch as his treatment before operation was the same as after it was perhaps fair to believe that some of the improvement was referable to the operation itself.

Cases of Thromboangiitis Obliterans.—Dr. Buerger showed four cases of thromboangiitis obliterans in which he pointed out some of the clinical manifestations and diagnostic signs of this disease. He called attention to the fact that in 1908 he had proposed the name thromboangiitis for a condition which had for many years been regarded as an endarteritic process (endarteritis obliterans). The patients demonstrated some of the remarkable features, such as the intense redness of the affected foot in the pendent position, to which the name of erythromelia might be applied. Dr. Buerger believed that this red condition was due to the chronic dilatation of the capillaries, a compensatory phenomenon indicating an attempt to make up for the impaired circulation. This manifestation was characteristic of the disease, although it might be present to a less degree in cases of atherosclerosis and diabetic gangrene. In one of the cases shown the rubor had persisted for many months, after the active symptoms of the disease had abated. Another of the symptoms was the marked ischemia in the elevated position, due to the fact that the blood was not able to reach the peripheral parts through the occluded vessels. Intermittent claudication was noted in the history of all of the cases presented. Indeed, it was found in a large percentage of the 200 cases observed. One of the patients gave the history of migrating phlebitis, which occurred in about 20 per cent. of the cases at some time or other of the disease. This migrating phlebitis might involve the superficial veins of the upper or lower extremities, might be one of the prodromal signs of the disease, might occur simultaneously with the affection of the deep vessels (arteries and veins) of the leg, and afforded the most excellent opportunity for studying the pathology of the disease. The superficial veins were accessible, could be excised, and histological studies could be made. In every case of migrating phlebitis it was wise, therefore, to excise a portion for pathological examination. Inasmuch as Dr. Buerger had demonstrated that a specific type of lesion occurred both in the deep vessels and in those affected with migrating phlebitis, and that the lesion was characteristic of the disease, a search for lesion in the affected veins was indicated in every case of migrating phlebitis. If present, it would signify that thromboangiitis was either already present, or might at any time affect the arteries of the lower extremity. Two of the patients demonstrated the fact that although ligation of the femoral vein might cause temporary improvement, the symptoms rapidly returned, so that they could not hope to obtain any definite result by such means. So far as the symptomatology and the diagnosis were concerned, the following was a brief summary of the important features upon which diagnosis might be based: (1) A history of intermittent claudication or pain in the calf of the leg or elsewhere in the foot upon walking in a Russian, Polish, or Galician Hebrew, practically always of the male sex. (2) The appearance of trophic disturbances in the form of ulcers. (3) The development of gangrene, usually dry gangrene of small extent, in most cases progressive; in other cases, leading simply to the loss of a phalanx or toe. (4) The development of vasomotor and circulatory disturbances, dependent upon the closure of peripheral vessels. (5) The presence of migrating phlebitis of the superficial veins of the upper or lower extremities. (6) The presence of certain objective signs, to wit: ischemia in the elevated position, marked rubor, or hyperemia, or erythromyelia in the pendent position; and the absence of the pulsation in the dorsalis pedis, sometimes the posterior tibial, popliteal, femoral, or even iliac arteries.

Transfusion and Splenectomy for Pernicious Anemia. Dr. Buerger reported the case of a young woman, 36 years of age, upon whom five transfusions had been done and the operation of splenectomy for pernicious anemia, the patient being to-day, five months after the splenectomy, in excellent condition considering herself perfectly well. The symptoms dated back to August, 1910, when she began to run down, symptoms of an intense anemia gradually developing. In January, 1912, the diagnosis of pernicious anemia was made and because of her wretched condition, in February, 1912, transfusion of blood was absolutely indicated. Her hemoglobin was 18 per cent., red blood count 800,000, white blood count 4,000. At that time she was

dyspneic, had generalized edema, her abdomen was distended with fluid, the liver was enlarged, palpable three fingers below the umbilicus. At the first transfusion her hemoglobin was raised to 36 per cent., and after this it rapidly rose, so that on May 6, 1912, two and one-half months after the first transfusion, her hemoglobin was 81 per cent., the red count 4,300,000. Her condition was excellent and she considered herself perfectly well. In September of the same year she still remained in excellent state, and in October her red blood count was almost five million (4,800,000), hemoglobin 81 per cent., and she said she had never felt better in her life. From this point on she remained in excellent health for about twenty months, after which she gradually began to decline, so that in January, 1914, it again became necessary to transfuse. During January, February, March, and April, 1914, it became necessary to transfuse four times in order to prepare the patient for splenectomy, which was done on May 1, 1914. Since that time her improvement had been so rapid that within two months after the operation she felt perfectly well again, and now, October 2, 1914, said she thought she was cured. Dr. Buerger said he did not wish to give the impression that the case presented was "cured," but desired to call attention to the fact that on two occasions it was possible to save the life of a patient suffering with pernicious anemia, once by means of transfusion alone, and then again, by two procedures, preliminary transfusions followed by splenectomy.

Tenoplasty for Ischemic Contracture.—Dr. BUERGER presented a case of ischemic contracture involving the right forearm of a boy, eight years of age, treated by means of plastic operation on the flexor tendons. The patient had sustained a fracture of both the radius and ulna eleven months before admission to the hospital, and, when the cast was removed five weeks later, inability to move the fingers and atrophy of the muscles of the forearm were noted. On admission to the hospital, July 10, 1914, the appearance of the hand was that of the typical claw hand or *main en griffe*, the fingers immobile, tightly clasped in the palm, the thumb adducted, the wrist atrophic, the muscles of the forearm wasted away. There was practically no active motion in any of the fingers. By means of a typical plastic operation done on the 15th of July, the eight tendons of the flexor sublimus and the flexor profundus group were each lengthened about 1½ to 2 inches, the tendons being split longitudinally in the classical manner. The palmaris longus was also treated in the same way. Cargyle membrane was placed between the tendons, and the wound closed without drainage. On the 9th of September a similar operation was performed in order to lengthen the deep flexor of the thumb and to overcome the adducted position brought about by the scar tissue. Dr. Buerger showed the case because an excellent result, both as regards cosmetic effect and the function of the fingers had been obtained. The hand could be held practically straight, the fingers could be completely extended and excellent motion in every one of them was present. In view of the fact that most operations for this condition were reported as unsuccessful, the case was of particular value in showing how valuable the procedure of tendon lengthening might be.

Dr. REGINALD H. SAYRE said that the result of the operation had been very satisfactory except that sufficient length had not been secured in the tendons to allow free motion of the fingers and the wrist. The operation of shortening the bones of the forearm did not seem, in the majority of cases, to give good results as a sufficient amount of bone was not removed to give play to the tendons, and if enough was removed to give this result marked shortening of the forearm was the result. Robert Jones had suggested a method of dealing with these cases which Dr. Sayre believed to be better than either of these open operations or intermittent massage. In almost all of these cases the chief damage was to the long flexors, the hand being in the *main en griffe* position. If the wrist was sharply flexed the fingers could be drawn slightly from the palm and retained in this position by a small splint. The patient's efforts to move the hand would in the course of a few days so stretch the flexor muscles that a straighter splint could be applied taking in not only the fingers, but the palm as well. After a short time a splint could be applied consisting of a palm piece and an arm piece joined by a strip of malleable iron which could be bent every few days forcing the hand further and further into a position of hyperextension. In this way, by putting into operation the principle of constant instead of intermittent stretching, remarkably fine results could be secured, exactly as was done in cases of congenital club foot. Dr. Sayre showed pictures demonstrating that cases could be treated in this way in a very satisfactory manner. He insisted upon the necessity of seeing fractured cases, and cases where a snug bandage had been applied, not later than five or six hours after the application of the bandage, and if there was any evidence of pain or swelling, that the bandage should be loosened until these symptoms were absolutely relieved. In experimental ischemia in animals it was found that if the pressure was relieved by the removal of the bandage not later than five hours after its application, recovery was perfect, but if the bandage was only slightly loosened, that ischemic paralysis resulted.

Purpura Hemorrhagica Treated by Blood Transfusion.—Dr. EDWARD W. PETERSON presented this patient, a boy two and a half years of age, who was admitted to the hospital on April 16, 1914. On April 12 he began to bleed from both ears, with some bleeding from the nose but not from the gums, mouth, or throat. A petechial rash appeared on his feet, legs, hands, and arms. Later large ecchymoses appeared on the forehead, under the eyes, and on the thighs and legs. The stools showed microscopical blood. The temperature and pulse were only slightly elevated; the boy was restless and irritable, and cried constantly. In the hemorrhagic diseases of the newborn, human blood serum and whole blood, injected subcutaneously, and blood given by transfusion had specific action in correcting the dyscrasia. In the purpuric diseases it would seem that this same line of treatment would prove beneficial. As yet it had not been tried in a sufficient number of cases to enable one to draw any definite conclusions as to its value. Other methods of treatment, however, being uncertain and unsatisfactory, it was determined in this case to do a blood transfusion. The seventeen year old brother acted as the donor. While waiting for the hemolysis and agglutination tests, which proved satisfactory, about 20 c.c. of whole blood was given subcutaneously. This transfusion was performed by the indirect "syringe-cannula" method of Linderman and proved most satisfactory and successful. The boy's appearance and disposition underwent an immediate change. The bleeding tendency ended abruptly and up to the present time had shown no disposition to recur.

Hemophilia Treated by Blood Transfusion.—Dr. PETERSON also reported the case of a girl, five years of age, with hemophilia; blood transfusion was tried, the mother being the donor, but with no success; a foreign donor was then tried. The patient did well for ten days and then she began to bleed from the gums and the nose. She became more and more anemic and three transfusions were given. Following this there were no further bleedings and she was discharged from the hospital two weeks later. She had since had a slight nose bleed.

Dr. WILLY MEYER said that his personal experience in the treatment of hemophilia by blood transfusion was not large. He reported the case of a patient with fibrosarcoma of the abdominal wall which was extirpated at the German Hospital. Recurrences occurred and, at this time, he did not know much regarding hemophilia. Several tumors were removed, the first from the suprapubic region. The parts were divided and he thought that he was going to get primary union. He left the dressings on for one week and then he found that the wound had suppurated. A coagulum was found in the wound. Upon investigation he found that this had been the experience of other surgeons. This was a true case of hemophilia. He then employed blood serum hypodermically and got good results. From three to five ounces of blood serum were injected hypodermically. After three or four weeks he did the major operation, a plastic operation with the silver filagree. No trouble whatever ensued and there was primary union. This proved to him what could be accomplished by this method.

Diaphragmatic Hernia Due to Stab Wound in the Chest.—Dr. MOSES S. KAKELS presented a man, twenty-three years of age, who on the night of admission to Lebanon Hospital, July 5, while in an altercation, suddenly felt a sharp sting over the left side of his chest and who almost immediately noticed his shirt full of blood. He did not experience much pain nor did he cough or expectorate any blood. He had no difficulty on deep inspiration, neither did he vomit at the time.

On admission he did not look acutely ill, though he vomited once, with no blood in the vomitus, shortly after he was admitted. There was a normal expansion of the chest; there was no pain on deep inspiration, no cough and the respiration was not accelerated. There was normal pulmonary resonance throughout with normal breathing and no râles were heard anywhere. The heart was normal and not displaced. The abdomen, however, was slightly distended, but there was no pain, tenderness or rigidity at any point. On his left side about two fingers breadth above the costal border in the linea mamillaris there was a small incised wound with clean cut edges about 1 cm. in length. This wound was surrounded by a firm mass which could be felt situated deeply under the skin. This proved at operation to be infiltrated blood. The wound was not probed but a sterile dressing was applied. The pulse and temperature were normal. The next morning his temperature rose to 101° F. and his pulse varied between 80 and 120. Rigidity below the free costal border was felt. This rigidity with the rise of temperature and pulse impelled the speaker to explore the abdominal cavity for some viscus injury. An incision was made over the left rectus muscle from the free costal border extending downward for a distance of about 12 cm. When the peritoneum was opened free and clotted blood escaped. On further exploration a part of the omentum about the size of a large hen's egg was found prolapsed into the opening in the left dome of the diaphragm close to the costochrondral articulation. The perforation in the diaphragm easily admitted the tips of three fingers. On further exploration no perforation of any of the abdominal viscera was found. At this stage of the operation the original stab wound was laid open by a transverse incision almost at right angles to the upper end of the primary incision. The cartilage of the ninth rib was found to be cut through the middle portion in a direction parallel to its long axis to the extent of about 3 cm. The muscles of the anterior thoracic wall were then stripped from the ribs and the eighth and ninth were cut through at the costochondral junction, the ribs elevated by traction of the diaphragm reflected back from the inner surface of the ribs. This gave a good exposure of the opening in the diaphragm which was about 3 cm. in length and was found to communicate between the abdominal and thoracic cavities. The opening was closed from above with interrupted chronic gut sutures. The ribs were then brought back into their original position and sutured in place with heavy chromic gut and the muscles also brought back in approximation. A cigarette drain was inserted at the upper edge of the primary incision down to the region of the kidney and a small rubber tissue drain at the lower angle of the skin incision. The skin was then sutured. The drains were removed after forty-eight hours. The wounds promptly healed without untoward symptoms and the patient was discharged on the fourteenth day after the operation perfectly well. From the situation of the wound of entrance and the opening in the diaphragm, the blade of the knife must have been thrust in an inward and backward direction and entered the space in the thoracic cavity between the reflection of the pleura and the origin of the diaphragm from the inner surface of the frame of the thorax without injuring the pleura or lung and then further penetrated the diaphragm, escaping a lesion of the abdominal viscera. As was well known the pleura never approached closely the lower border of the chest; at the sides, in fact, in the axillary line below the reflection of the pleura and the origin of the diaphragm, the space was about 5 cm. on the right and 4 cm. on the left. Had any of the organs of the thoracic or abdominal cavities been injured the outcome might not have been so favorable. It was a good rule in stab or bullet wounds of the chest or abdomen to immediately explore upon the slightest suspicion of hemorrhage or injury to underlying organs.

Bronchial Fistula.—Dr. WALTON MARTIN presented this paper. He said that by broncho-cutaneous fistula he meant a persistent passage between the lung (one of the air spaces or bronchi) and the surface of the body. In such a condition air might pass with the respiratory movements through the fistulous tract and colored solutions injected into the fistula were immediately expectorated. In using the term pulmonary fistula, the implication was that the tract had existed for some time, and its walls were well organized and the condition was persistent. These fistulæ might be caused by tuberculosis, actinomycosis, echinococcus cysts, gangrene of the lung, or carcinoma of the chest wall. A few cases had been reported of fistulæ resulting from abscesses having their origin in the mediastinal lymph glands, or the vertebral column. The decision whether or not a persistent cutaneous fistula communicated with a bronchus might be comparatively easy if the tract was short and straight; if, however, it was narrow and tortuous it was more difficult to diagnose. A small amount of aqueous solution of methylene blue injected into the sinus produced violent coughing and blue stained sputum was immediately expectorated if the tract communicated with a bronchus. In long standing fistulæ with much thickening of the tract this method was not harmful unless large quantities of the methelene blue solution were injected. By this means the diagnosis of a tortuous fistula was not difficult, but it was very difficult to recognize the extent of the fistula and the nature of its communication with the lung and the pleura. The *x*-ray examination of these patients was unsatisfactory owing to the thickening of the pleura and the changes in the lung. In a general way the fistulæ might be grouped into four classes: (1) Those showing a straight fistulous tract from the skin to the bronchus. A case reported by Walther before the Surgical Society of Paris, 1904, showed this condition. (2) Those fistulæ in which the tract was bulbous at the end, that was, flask-shaped with the belly of the flask in the lung substance, and the neck opening on the skin. This was the condition after the opening of an abscess in the lung when the pulmonary and parietal pleuræ were adherent. (3) Those fistulæ in which the tract was spindle-shaped, there being a small opening into the lung and a small cutaneous opening while the intervening portion was of considerable size. (4) Those in which the fistulous tract was dumb-bell shaped with the portion in the lung and near the surface being dilated with a narrow intervening portion. The fourth case in Dr. Martin's series was of this kind. The fistulous tract was partly made up of granulation tissue or was covered over by epithelium. A certain number of simple straight fistulæ closed of themselves or after cauterizing the fistulous tract. If, however, the fistula persisted, it was fair to assume that there was little chance to close the tract without an operation. If there was a bulbous enlargement in the lung substance, the sinus had a tendency to persist on account of the insufficient drainage; here the indication was to keep the widened fistulous tract well opened until the pulmonary portion contracted down and to keep the entire tract as clean as possible. In these cases the writer had found gentle irrigation with methylene blue of benefit. The violent coughing made it necessary to use it with caution. The drainage tube in these cases must be very gradually shortened. In the cases in which there was a considerable intrapleural enlargement of the sinus, it was necessary to do an extensive operation, usually a Shede-Delorme.

Dr. Martin reported the following cases:

CASE I.—This patient was 38 years of age and gave a history of metapneumonic empyema, thoracotomy, and persistent thoracic sinus for seven years. For the past three years the expectoration had been profuse and foul smelling. The sputum showed no tubercle bacilli. At operation a large cavity was found in the pleura and communicated with the lung. Methylene blue injected into the sinus was immediately expectorated. A Shede-Delorme operation was performed which was followed by a partial recovery, the patient being able to resume his work as a hod-carrier. He died four years later of pneumococcus meningitis.

CASE II.—This patient, 17 years of age, gave a history of empyema, probably intralobular with rupture into a bronchus, thoracotomy and persistent thoracic sinus. The injection of methylene blue was followed immediately by expectoration. At operation the seventh and eighth ribs were removed. A purulent cavity was found in the pleura and obliterated. The sinus then closed after about two months.

CASE III.—This patient was 47 years of age and gave a history of metapneumonic empyema, thoracotomy, and persistent thoracic sinus for six months. Under daily irrigations with methylene blue and two injections of Mostig filling the patient recovered.

CASE IV.—This patient, 27 years of age, also gave a history of metapneumonic empyema 16 months previously, of thoracotomy, and persistent cough with foul smelling expectoration. A culture from the pus gave a Gram-positive diplococcus. The eighth rib was resected. An abscess, probably pleural, was opened, but a sinus persisted. A second operation was performed four months later, a portion of the chest wall being resected together with a portion of the lung forming

the outer wall of the sinus. The patient succumbed about six hours after the operation from inhalation of pus and blood into the sound lung.

CASE V.—This patient was 44 years of age and had had an operation five months previous for empyema. Although the sinus nearly closed the patient had an elevation of temperature in the afternoon and felt ill. About four weeks later a persistent cough developed with mucopurulent expectoration. The thoracic sinus closed and then reopened. At operation, portions of the fifth, sixth, seventh ribs, and parietal pleura were removed, exposing a fairly large cavity with an opening into the lung at one point. The improvement after the operation was marked. The cough had entirely stopped. This patient was still under treatment.

Dr. DEXTER DAVID ASHLEY reported the case of a boy, twelve or thirteen years of age, who had a tuberculous process of the spine. After a seeming recovery from the disease he became quite an athlete. Last summer while canoeing he had some expectoration, became much reduced in flesh and complained of pain in his back. On examination a well developed psoas abscess was found. In about two weeks an abscess broke through the lung and then the psoas abscess entirely disappeared. A few weeks later a rise in temperature appeared, about 100° F., but the patient seemed to be well. The patient became much emaciated and discharged large amounts of pus through the mouth. Two weeks later he developed meningeal symptoms and died.

Dr. EDWIN BEER recalled an instance in which the empyemic sinus was swabbed with a solution of nitrate of silver; irritation was set up, with collapse, and death following.

Dr. DEWITT STETTEN reported a case seen at the German Hospital a few years ago. This was a case of pulmonary abscess and all therapeutic measures had failed. The patient died after operation. This case was reported by Dr. Kammerer at a meeting of the New York Surgical Society.

Is Thromboangiitis Obliterans an Infectious Disease?—Dr. LEO BUERGER presented this paper which was the result of a collection of clinical data and pathological material which he had been collecting since 1904. He stated that during the past eight years some 200 cases of presenile gangrene, a condition which the Germans described under the term *endarteritis obliterans* and for which he had proposed the term *thromboangiitis obliterans*, had come under his observation. The disease was one which, curiously enough, seemed to afflict almost exclusively the immigrant Jewish population, particularly the immigrants and their children from Poland, Galicia, and Russia. The speaker said it would be superfluous to present a record of all the facts and observations that he had gathered from this large amount of material but that he wished to present the conclusions which he regarded as significant from the standpoint of pathology and etiology. He believed they were warranted in thoroughly supporting the proposition that *thromboangiitis obliterans* was an infectious disease in which a specific type of organism was at work, and that although it had not been possible to demonstrate either bacteriologically or morphologically the presence of the offending agent, the pathological findings clearly indicated whether future studies should be directed in order that the causative factor might be discovered. The finding of a peculiar type of histological picture in certain of the veins and arteries led the writer to believe that the same determining cause which led to the thrombosis also evoked the changes in the media, adventitia, and perivascular connective tissue; and furthermore that although the mechanical conditions that obtained in the lower extremities and the arteriosclerotic changes might be factors, some additional agent, toxic or otherwise, was at the same time responsible for the production of the periarteritis and the thrombosis. From a report of eleven cases in 1909 Dr. Buerger believed the following conclusions were warranted: 1. The disease thromboangiitis obliterans was often associated with thrombophlebitis of superficial veins of the arms and legs. 2. Certain peculiar cutaneous nodosities were characteristic manifestations in many of the cases. 3. The disease of the superficial veins might be subsidiary, or it might dominate the clinical picture. Objective signs referable to these vessels should be regarded as extremely suspicious marks of the synchronous development of thromboangiitis obliterans. In the presence of migrating phlebitis or cutaneous nodosities one should carefully search for evidence of thromboangiitis obliterans, in the form of pulseless vessels, erythromelia, blanching of the leg in the elevated posture, cold and blue toes, pain in the calf of the leg brought on by walking, and other physical phenomena. 4. Migrating thrombophlebitis might give no symptoms, the signs referable to the deep vessels being of most importance. 5. Patients might suffer at one time from the migrating thrombophlebitis, at another from the progress of occlusive change in the deeper vessels. 6. Certain cases suggested the possibility that attacks of trouble in the surface veins might occur simultaneously with similar exacerbations of disease in deep vessels of another limb. 7. The morbid process resulting in the production of cutaneous nodosities and throbosed superficial veins was independent of varicosities, of infections, or of trophic disorders in the territory which they drained. 8. The vessels of the upper extremity might be affected by the lesion thromboangiitis obliterans. 9. Thrombophlebitis in the arm and forearm should arouse one's suspicions as regards involvement of the deep vessels of the legs. 10. Further studies should be directed towards solving the relationship between the two thrombotic lesions that have been described. Since 1909 the author had been able to gather data on twelve additional cases in which the superficial veins were involved and had brought the number of exsected veins to twenty-five. In these both the acute and the healed stage of the disease were found. From a consideration of the pathological picture the conclusion was reached that a specific characteristic lesion of thromboangiitis obliterans might affect the deep as well as the superficial vessels, and that it was from the lesions in the veins that they should be able to gain access to material for investigation of the causative agent. For the purpose of demonstrating the sequence of the various stages of the pathological process, from its earliest obtainable stage up to the "healed" or obliterated connective tissue stage and to make clear the argument in favor of his theory, the writer presented a series of selected histological pictures, pointing out the general appearance of the old lesions in the deep vessels, the acute type of the lesion in the deep vessels and arteries, the lesions as seen in the veins under the skin and how these latter were identical with the lesion of thromboangiitis obliterans, and finally why the findings pointed so suggestively to the presence of some microbial agent although none had yet been revealed. Although there were still many mooted points for investigation he believed that the correctness of the following points had been demonstrated: First, that thrombo-angiitis obliterans was a disease in which the acute inflammatory lesion and occlusive thrombosis of arteries and veins were the characteristic lesions. Second, that from the mechanical point of view and from the standpoint of symptomatology, the thrombotic occlusion was the most important phenomenon. Third, that the thrombosis was probably preceded, and certainly accompanied, by an acute inflammatory or exudative stage. Fourth, that the lesion involved deep veins in about 40 per cent. of the cases, the superficial veins of the upper and lower extremity in 20 per cent. of the cases. Fifth, that recent investigations of the veins showed that the acute lesions in the superficial vessels and in the deep vessels were identical. Sixth, that the histological changes in the veins pointed to the existence of an infectious process. Seventh, that they believed that future studies should be directed towards the discovery of the causative agent in the specimens cut out from the superficial veins when they were the seat of acute thrombophlebitis. In this way it was to be hoped that the etiology of the disease might soon be revealed.

Dr. CHARLES GOODMAN said that during the past twenty years he had had experience with about seventeen cases, cases that had been observed for various lengths of time, two over eighteen years. In almost all cases there was a history of cigarette smoking. The Wassermann reaction, with but two exceptions, was negative. Dr. Goodman was led to believe that the process as far as the arteries were concerned, was an ascending one. He had seen an obliteration of pulsation in the dorsal artery of the foot, a few weeks later that of the tibial, and finally in the femoral as far as the iliac. Many of these cases showed a retention of the calcium salts. Examination of blood serum seemed to indicate a disturbance of the efficiency of the suprarenal glands which suggested a form of treatment. Koge of Professor Ito's clinic attempted to reduce the viscosity of the blood by means of Ringer's solution. They tried the treatment at the Beth Israel Hospital

and obtained temporary amelioration of the symptoms in two patients and with no results in a third case. In 1902 the Spanish surgeon Satrustegui suggested substituting part of the venous system for the occluded arteries. Dr. Goodman's personal experience covered seventeen attempts. In three instances an exposure of the femoral artery showed that it was occluded and felt like a whipcord. In fourteen patients he performed an arteriovenous anastomosis followed by strong presumptive evidence that a reversal of the circulation in the limb was accomplished. There was an increased warmth of the limb in all the cases; also an improvement in color; pain was relieved; the superficial veins became filled, and pulsation was present below the anastomosis. The operation of course did not perform a cure in all cases, but Dr. Goodman believed that in carefully selected cases performed before gangrene set in, the condition could be averted and the life of the limb prolonged.

State Medical Licensing Boards.

STATE BOARD EXAMINATION QUESTIONS.

TENNESSEE STATE BOARD OF MEDICAL EXAMINERS.

May 4 and 5, 1914.

ANATOMY.

1. Give the formation of brachial plexus and the principal branches of same.
2. Name the branches of the femoral artery and give its anatomical relations in Scarpa's triangle.
3. Describe the shoulder joint and give its blood and nerve supply.
4. What is origin, point of escape, and distribution of the seventh cranial nerve.
5. Describe the temporal bone and give its articulations.
6. Name the superficial and deep groups of the flexor muscles of the forearm.
7. Give the boundaries of the inguinal canal.
8. Describe the colon.

PHYSIOLOGY.

1. Give relations of chemical changes in muscular contraction to fatigue and give the chemical theory of fatigue.
2. Give briefly the theories of muscular contraction.
3. Give the neuron doctrine.
4. Give the general properties of the blood and its histological structure.
5. Give the neurogenic and myogenic theories of the heart-beat and describe the automaticity of the heart.
6. Define dyspnea, giving its physiological causes; hyperpnea, and apnea, giving their physiological causes.
7. Describe dichromatic vision and give the tests for it, also describe achromatic vision.
8. Briefly define diffusion, dialysis, and osmosis and describe osmotic pressure.

ANSWERS.

ANATOMY.

1. The *brachial plexus* is formed by the union and subsequent division of the anterior divisions of the fifth, sixth, seventh, and eighth cervical and the first dorsal nerves. The union of the fifth and sixth makes the upper trunk; the seventh forms the middle trunk, and the eighth cervical and first dorsal make the lower trunk. Each of these trunks is divided into an anterior and a posterior branch. The anterior branches, from the upper and middle trunks, make the upper or outer cord of the plexus; the anterior branch of the lower trunk becomes the lower or inner cord; the three posterior branches unite to form the posterior or middle cord. The plexus lies between the Scalenus anticus and medius. The *branches* are: (1) Above the clavicle; communicating, muscular, posterior thoracic, and suprascapular. (2) *From outer cord:* External anterior thoracic, musculocutaneous, and outer head of median. (3) *From inner cord:* Internal anterior thoracic, lesser internal cutaneous, ulnar, and inner head of median. (4) *From posterior cord:* Subscapular, circumflex, and musculospiral.

2. The *branches of the femoral artery*, are: Superficial epigastric, superficial circumflex iliac, superficial external pudic, deep external pudic, muscular, anastomotica magna, and profunda femoris (with branches: external circumflex, internal circumflex, and three perforating). The artery passes from the base to the apex of Scarpa's triangle, it has the femoral vein on its inner side, and the anterior crural nerve on its outer side; it is covered by the skin and superficial fascia.

3. The *shoulder-joint* is an enarthrodial joint formed above by the glenoid cavity of the scapula and below by the head of the humerus. Its ligaments are glenoid, coraco-humeral, and capsular. The glenoid surrounds the edge, deepens the glenoid cavity, and is continuous above with the long head of the biceps tendon. The capsular ligament, extensive and loose, arises above it from circumference of glenoid cavity behind the ligament, is attached below to the anatomical neck of humerus, and is pierced by tendons of two or three muscles. The coraco-humeral, or accessory, is a fibrous band which extends obliquely downward and outward from the coracoid process to the anterior part of great tuberosity, strengthening the capsular ligament. A *synovial membrane* lines the joint, and forms the bursa under the subscapularis. It is reflected round the tendon of the biceps, and lines the bicipital groove. The *nerve supply* is from the circumflex and suprascapular nerves. The *arteries* are branches of the anterior and posterior circumflex, and the suprascapular.

4. The seventh cranial nerve has its superficial origin in the medulla oblongata, in the groove between the olivary and restiform bodies; it leaves the skull through the stylomastoid foramen; it is distributed to the muscles of expression of the face, the muscles of the external ear, the Platysma, Buccinator, Stylohyoid, and the posterior belly of the Digastric.

5. The *temporal bone* consists of three parts—the squamous, the mastoid and the petrous parts. The *squamous* portion is the anterior and upper part of the bone, and presents an external and internal surface, and a superior and inferior border; the chief points on it are the zygoma, temporal ridge, eminentia articularis and glenoid fossa. The *mastoid* portion consists of an outer and inner surface, and presents mastoid foramen, mastoid process, digastric fossa, sigmoid fossa, mastoid cells and mastoid antrum. The *petrous* portion presents an apex; superior, anterior, posterior and inferior surfaces, and three borders; on it are the canal of Huguier, internal auditory meatus, aqueduct of Fallopius, jugular fossa, stylomastoid foramen, carotid canal, and styloid process. It gives attachment to the following muscles: Temporal, masseter, occipitofrontalis, sternomastoid, splenius capitis, trachelomastoid, digastric, posterior, auricular, stylohyoid, stylopharyngeus, styloglossus, levator palati, tensor tympani, tensor palati, and stapedius. It *articulates with:* Occipital, parietal, sphenoid, malar, and inferior maxillary bones.

6. FLEXOR MUSCLES OF FOREARM. *Superficial group:* Pronator radii teres, flexor carpi ulnaris, flexor carpi radialis, palmaris longus, and flexor sublimis digitorum. *Deep group:* Flexor profundus digitorum, flexor longus pollicis, and pronator quadratus.

7. BOUNDARIES OF THE INGUINAL CANAL. *In front:* the skin, superficial fascia, aponeurosis of the external oblique, and (for its outer third) the internal oblique. *Behind:* the conjoined tendon, the triangular fascia, the transversalis fascia, subperitoneal fat, and peritoneum. *Above:* the fibers of the internal oblique and transversalis. *Below:* Poupart's ligament and the transversalis fascia.

8. The colon is divided into ascending, transverse descending, iliac, and pelvic.

The *ascending colon* extends from the cecum to the under surface of the liver to the right of the gall-bladder, where it turns to the left, forming the *hepatic flexure*. It lies in the right iliac and right hypochrondriac regions. The peritoneum covers the anterior and lateral surfaces. Length, 8 inches. *Relations.—In front:* The convolutions of the ileum; *behind:* Iliacus, quadratus lumborum, outer side of right kidney.

The *transverse colon* passes from right to left, from the gall-bladder to the spleen. It forms an arch, convex anteriorly and below: the *transverse arch of the colon*. It is entirely surrounded by peritoneum, which is attached posteriorly to the spine, forming the mesocolon. Length, 20 inches. *Relations.—Above:* Liver, gall-bladder, large curvature of stomach, lower end of spleen; *below:* small intestines; *anteriorly:* anterior layers of great omentum, anterior abdominal wall; *posteriorly:* right kidney, second part of duodenum, transverse mesocolon, pancreas, and small intestines.

The *descending colon* passes from the end of the transverse colon by a bend, *the splenic flexure*. Between

the splenic flexure and the diaphragm, opposite the tenth left rib, is a fold of the peritoneum, the *costocolic ligament*, which slings up the spleen. The gut then passes downward to the iliac crest, ending in the iliac colon. The peritoneum invests its anterior and lateral surfaces. Length, 4 to 6 inches. *Relations.—Behind:* left crus, left kidney, quadratus lumborum, and psoas; *in front:* small intestines; *inner side:* outer border of left kidney.

The *iliac colon* is continuous with the descending colon at the left iliac crest, and ends at the inner border of the left psoas. Peritoneum invests its anterior and lateral surfaces; it has no mesentery. Length, 5 to 6 inches. *Relations.—In front:* Small intestines; when distended, the anterior abdominal wall; *behind:* left iliopsoas.

The *pelvic colon* extends from the inner border of the psoas to the level of the third sacral vertebra. Length, 16 or 17 inches; very variable. It has an extensive mesentery. *Relations.*—Passing over left brim of pelvis, it crosses the left external iliac vessels and left ureter, and passes to right margin of pelvis, resting on bladder in male and uterus in female; above lie coils of small intestine. It then turns back to midline on posterior wall of pelvis, and, forming a second bend, descends to end in the rectum.—(From *Aids to Anatomy.*)

PHYSIOLOGY

1. *Fatigue.* "If several successive stimuli are sent into a nerve of a nerve-muscle preparation, each succeeding one not taking effect, however, until the influence of the preceding one has passed off, after a time the contracting muscle becomes fatigued.....In fatigue thus produced, the structures present are the nerve, motor end organs, and the muscle; the nerve was excited by repeated single induction shocks. Fatigue in this case is due: (i) to the consumption of those substances, especially carbohydrates, which normally exist in muscle, and which are available for the supply of muscle energy, and (ii) to the accumulation of the waste product of contraction, such as CO_2 and sarcolactic acid. These seem to be the chief source of fatigue, for if the muscle is allowed to rest and is then washed with 0.9 per cent. NaCl solution which contains a little alkali, fatigue gradually passes off. Moreover, fatigue may be artificially produced in muscle by feeding it with a weak solution of sarco-lactic acid.....In conclusion, it may be stated that the chief seat of fatigue is in the nerve cells of the brain and spinal cord, but that it also occurs in the motor end organs; that, in ordinary circumstances, fatigue cannot be demonstrated as occurring either in medullated or in non-medullated nerves. The fatigue, which occurs in the muscular fibers themselves, is due to the using up of those substances present in the tissue which, when oxidized, give rise to heat and energy. As in normal circumstances these substances are readily replaced by means of the blood and the lymph, it may be concluded that, under normal conditions of nutrition, fatigue does not occur in the muscle fibres themselves."—(Lyle's *Physiology.*)

2. The *modes of action of muscle.* "We know the probable structure of cross-striated muscle, substantially, so far, at least, as appearances go. We know that it consists of two sorts of substances, one (anisotropic) doubly refracting polarized light, the other (isotropic) refracting it singly. We know that when the contraction occurs in cross-striated muscle the latter kind of material changes its place somewhat, while the former kind does not do so. We are sure that the metabolism of all sorts of muscle is, in part, the oxidation of carbohydrates and of protein, sarcolactic acid being a way-product, and carbon dioxide and water among the end-products. The more active the contraction of the muscle the more oxygen it consumes and the more carbon dioxide is liberated from it. We know that, as often happens in protoplasm, the chemism of metabolism gives rise to at least three sorts of kinetic energy: movement, heat, and electricity, for these may be measured and variously studied. If we start out with the fact that it is chemism undoubtedly which liberates these energies, we have the basis of the chief various theories of muscle-action. To one (Engelmann) it seems clear enough that the chemism gives rise to heat, which, by causing imbibition of sarcoplasm, brings about the contraction. Another "school" (Pflüger, Bernstein, Verworn, Fick) supposes that the chemism directly, i. e., without the intervention of heat, alters the two differing substances in such a way that the isotropic one swells into the anisotropic. A recent group of thinkers (Müller, Loeb) supposes that electricity is involved in causing the contraction. To others (e. g., Weber), the chemism seems to alter the natural elasticity of the myoids or fibrils, making them shorten and then lengthen. Numerous other hypotheses still less probable have been published at various times."—(Dearborn's *Physiology.*) Other theories are the thermodynamic theory and the surface tension theory.

3. The *neurone doctrine* teaches that the nervous system is composed of neurones; these neurones consist of a nerve cell and various processes; the peripheral nerves are the long processes. The neurones connect with each other by contact only, and are not continuous. The axon of the neurones is in contact with the dendrites or cell body of another neurone. The nerve conduction in the dendrites is away from the nerve cell, that in the axons is towards the cell body.

4. The *physical properties of blood:* Fluid, somewhat viscid, red; specific gravity, from 1055 to 1062; alkaline reaction; saltish taste; characteristic odor; variable temperature (average, about 100° F.).

The *constituents of the blood* are plasma and corpuscles. The *plasma* consists of water and solids (proteids, extractives, and inorganic salts). The *red corpuscles* consist of water and solids (hemoglobin, proteids, fat, and inorganic salts). The *white corpuscles* consist of water and solids (proteid, leuconuclein, lecithin, histon, etc.).

The *red blood corpuscles* are biconcave discs, about 1-3200 of an inch in diameter; they are non-nucleated, and there are about 4,500,000 or 5,000,000 of them in each cubic millimeter of blood. They are elastic and soft, and their shape is changed by pressure, but is promptly regained on the removal of the pressure. Their color is yellowish. They contain hemoglobin.

Their *function* is to carry oxygen from the lungs to the tissues.

The white blood cells are spheroidal masses, varying in size, having no cell wall, and containing one or more nuclei; there are about 7,000 to 10,000 of them in each cubic millimeter of blood. They differ much in appearance, and are divided into (1) small mononuclear leucocytes, or lymphocytes, (2) large mononuclear, (3) transitional, (4) polynuclear, or polymorphonuclear, or neutrophile, and (5) eosinophile. They are all more or less granular, particularly the last two varieties named. They are probably formed in the spleen, lymphatic glands, and lymphoid tissues. Their fate is uncertain; it has been asserted that they are converted into red blood cells; they play a part in the formation of fibrin ferment; they are sometimes converted into pus cells. Their functions are (1) to serve as a protection to the body from the incursions of pathogenic microrganisms; (2) they take some part in the process of the coagulation of the blood; (3) they aid in the absorption of fats and peptones from the intestine, and (4) they help to maintain the proper proteid content of the blood plasma.

There are also *platelets*, which are very small, colorless, irregular shaped bodies; they are about one-fourth the diameter of a red corpuscle. Their function is not determined; it is possible that they take some part in the coagulation of the blood. In number they vary from about 200,000 to more than 500,000 in each cubic millimeter of blood.

Plasma conveys nutriment to the tissue; it holds in solution the carbon dioxide and water which it receives from the tissues, and takes them to be eliminated by the lungs, kidneys, and skin; it also holds in solution urea and other nitrogenous substances that are taken to and excreted by the liver or kidneys.

5. "The *neurogenic theory of heart beat* supposes that the internal stimulus to the heart beat arises within the nerve cells which are present at the venous end of the heart, and that the excitatory wave is conducted by nerves."

"The *myogenic theory* supposes that the heart muscle itself possesses the property of automatic rhythmicality, and that this property is most marked at the venous end of the heart, and at the sinu-auricular and auriculo-ventricular junctions. The contraction wave is generated at the venous end of the heart in the muscle, and, in virtue of the conductivity of cardiac muscle, spreads over the muscle tissue of the auricles, and thence over the ventricles. In other words, the contraction wave commences in muscle and is conducted by muscle. The muscular continuity of the auricles and ventricles is brought about by the auriculo-ventricular bundle of His."—(Lyle's *Physiology.*)

"*Automaticity.*—Inasmuch as the heart continues to

contract in a perfectly rhythmic manner after removal from the body and apparently without the aid of an external stimulus, it is said that the heart-muscle is automatic or spontaneous in action. Strictly speaking, however, this is not the case, for the reason that all movement, that of the heart included, is the resultant of the action of natural causes though their true nature may be beyond the reach of present methods of investigation."—(Brubaker's *Physiology.*)

6. *Dyspnea* means difficult breathing, and denotes any increase in the force or rate of the respiratory movements.

Dyspnea may be caused by: Stimulation of sensory nerves, increase of carbon dioxide or diminution of oxygen in the blood.

Hyperpnea means exaggerated respiratory action.

Apnea means cessation of respiratory action; it is often used for the term asphyxiation. It is due to prolonged and rapid ventilation of the lung. Asphyxia is suffocation, due to depriving the lungs of oxygen. It is caused by preventing oxygen from reaching the lungs; by obstruction of the respiratory passages; by inhaling a gas without oxygen, or one which strongly tends to displace oxygen from the hemoglobin, as carbon monoxide; or by interfering with the change of gases which should take place between the air and the blood.

7. In the *dichromatic*, color vision is represented by two fundamental colors and their combinations with white or black; the *achromatic* are totally color blind, and only see the white-gray-black lines.

The most common form of *dichromatic vision* is red or red-green blindness.

Tests are made by means of Holmgren's skeins of wool. "A number of skeins of wool are used and three test colors are chosen, namely, (1) a pale pure green skein, which must not incline toward yellow green; (2) a medium purple (magenta) skein; and (3) a vivid red skein. The person under investigation is given skein 1 and is asked to select from the pile of assorted colored skeins those that have a similar color value. He is not to make an exact match, but to select those that appear to have the same color. Those who are red or green blind will see the test skein as a gray with some yellow or blue shade and will select, therefore, not only the green skeins, but the grays or grayish yellow and blue skeins. To ascertain whether the individual is red or green blind tests 2 and 3 may then be employed. With test 2, medium purple, the red blind will select, in addition to other purples, only blues or violets; the green blind will select as "confusion colors" only greens and grays. With test 3, red, the red blind will select as confusion colors greens, grays, or browns less luminous than the test color, while the green blind will select greens, grays, or browns or a greater brightness than the test."—(Howell's *Physiology.*)

8. "The term *diffusion* has long been applied to the regular mixing of the molecules of two gases when brought into contact in a confined space. More recently it has been applied to the mixing of the molecules of two solutions when brought into contact. If, however, the two solutions are separated by a membrane, permeable to the solutions, diffusion will still occur. To this form of diffusion the term *Osmosis* has been applied in the case of water, and *Dialysis* in the case of diffusible substances. All bodies can be divided into two groups, *crystalloids* and *colloids*. To the former group belong bodies having a crystalline form, which readily go into solution in water. All such bodies are diffusible (dialyzable), their power of dialysis, however, varying considerably. To the second group belong such bodies as have no crystalline form (amorphous). These are generally bodies with a large molecule, which form colloidal suspensions in water, and are only slightly or not at all diffusible. An exception to this second group is hemoglobin, which has a very large molecule but is crystalline and is diffusible."—Kirkes' *Physiology.*)

"*Osmotic* pressure may be defined as the pressure exerted by the molecules of the substance in solution against an enclosing wall, in consequence of which there is an osmosis of the surrounding solvent towards it. The reason for this pressure lies in the fact that, when the molecules of a substance are separated a certain distance, as they are when in solution, they repulse one another as do the molecules of a gas and in their flight strike against the outer layer of the solvent. The pressure of the molecules of a substance in solution is therefore comparable to the pressure of the molecules of a gas. Three methods may be employed for measuring the force of the osmotic pressure of different substances, viz.: 1. Physical. 2. The determination of the freezing point. 3. By calculation."—(Brubaker's *Physiology.*)

†Applicants should in every case write to the secretary for all the details regarding the examination in any particular State.

Extradural Hemorrhage Causing Aphasia.—V. Z. Cope reports the case of a male, aged 29, who was struck over the left temple on August 4, 1913. He was unconscious for a time and had not regained full consciousness when he came under the author's care on August 5. On admission his pulse was 50 and respiration 20 and he was drowsy but could be roused. The knee-jerks were slightly exaggerated and the pupils were equal and reacted normally. There was slight swelling and bruising over the site of injury. In the absence of localizing symptoms no operation was considered advisable. For some days the condition improved, so that he could answer questions sensibly, but it was noticeable that after giving a sensible answer his speech would tail off into a jumble of disconnected nonsense. Nine days after admission his right pupil became larger than the left and early optic neuritis was found. The pulse still remained 50 to the minute. Operation was undertaken on August 15. The skull was trephined over the anterior branch of the left middle meningeal artery. An ounce or more of old-blood-clot was found outside the dura, extending down to the skull base, and two depressed pieces of bone were removed. The dura was not opened. No drainage. Recovery was very rapid after operation. Speech was soon quite perfect and pulse normal. The patient was discharged from hospital just a fortnight after operation.—*Proceedings of the Royal Society of Medicine.*

THE PUBLIC AND THE PROFESSION: A CRITICISM.*

BY D'ORSAY HECHT, M.D.,

CHICAGO, ILLINOIS.

IN the vast scheme of the eternal unfitness of things, audiences for whatsoever purposes foregathered have these many years been put under the painful necessity of listening to addresses characterized by the length and doubtful strength that beget lassitude. That we have them with us still—I mean the audiences—is cause for not a little wonderment and satisfaction. Coming down through the ages of speeches and speakers, their survival must be owing to qualities of inherent graciousness and acquired toughness, both of which I think I perceive in my audience of this evening, and behind which I shall need to take refuge.

It should not be outside the scope of my remarks at this point to reiterate how deeply I feel the honor at being permitted to preside over the deliberations of an association which, in an ever enlarging sphere of activity, has these forty years exercised an influence for good probably beyond the fondest forecast of its founders. Apart from its rôle in the diffusion of scientific knowledge, its participation in human welfare movements, its endorsement of higher educational standards, its interest from time to time in setting ethics right side up—apart from these, I say, this association has been at great pains to facilitate and foster those social contacts of which Lowell somewhere has said: "They are as wholesome for the character as solicitude is needful for the imagination." Whatever else social contacts may achieve, they have provided us with an *esprit de corps* which is not the least enviable of our possessions.

In this connection some words of respectful appreciation seem due my fellow officers and fellow members for their innumerable expressions and acts of friendliness and loyalty during the term of my incumbency. It is because I lack so many of the qualifications which my predecessors in this agreeable office enjoyed that I am especially beholden to them for their help. The gentlemen of the profession of Cincinnati have placed us much in their debt, for they have made possible this occasion and surrounded it with all those genuine and wholehearted measures of hospitality that should make this meeting memorable to us all.

It is well-nigh a truism that as a people we here in America work intensively, breathlessly, in our solicitude for success, for the most part quick material success. Now, if such success were contingent upon mere work, or even overwork, meaning energy well-timed, well-measured and reasonably confined to the task at hand, it would bring with it no penalty. For I am quite firmly of the opinion that the modern business man, for instance, does not collapse because of the kind of work he has to do, nor the amount of it. The nervous bankrupts who crowd our consulting rooms or find a more agreeable retreat in sanatoria are not properly objects of pity, as disciples of work. Their type has come about in part from not knowing how to work, but in much greater part from a perverse attitude of mind engendered by the artificialities of our social institutions. Curiously enough, our countrymen delight in the convulsive efforts of their daily lives. These seem to them particularly illuminating and satisfying, and they point with unfailing pride at the over-tension now so much a part of human activity as a redeeming physiological quality rather than the bad habit it really is. Even in our leisure, as in our labor, a "bottled lightning quality," to which James has alluded, is constantly with us. Captains of industry dine in rooms—designated as clubs—adjoining their offices; women make frenzied shopping tours the order of the day; railroad officials offer eighteen hour speed trains, with rebates for delays; motor cars are housed behind mortgaged dwellings; golf is reenforced by a single sandwich and timed hole for hole by a wrist watch; the dinner coat is donned down town to save time. Whatsoever the end, it is consummated in a hurry, and if you ask the most bustling of women and hustling of men how well they keep up with their schedule, they confess to never being quite caught up.

Now, if we are to believe the psychologists, and I think we may, who have shown that "invention and imitation taken together form the entire warp and woof of human life in so far as it is social," then clearly it is the emulative spirit in the masses, the pervading influence of "everybody's doing it," to use a vulgarism, that is robbing us of so much of our inner and outer serenity. The advantage of this somewhat incidental reference to an ample fault in our American makeup is the opportunity it affords to gently remind an unsuspecting profession that on many sides it, too, is beset with those tricks of tension that create the illusion of energy, and for which we pay in the end with inefficiency. There is no blinking the fact that some of these tricks have their origin in the anxiety of the physician for the future, his concern for an income that shall in the declining years suffice for his own real needs and perchance those of his family. To insist, however, that more than a small share of our excesses on the side of hurry, breathlessness, impulse and enthusiasm have to do with mere money-getting is to miss the root of the matter. No doubt some of our display of tension is traceable to a failure of complete adjustment in the face of the rapid and radical transformations that have characterized

*President's address, Mississippi Valley Medical Association, Cincinnati, October 27-29, 1914.

the course of American medicine in the past decades. But for the real reason of our style of work and play as a profession we shall have to go to social psychology and find with Royce and James and Baldwin that it lies with us as individuals, with our bad habits, "bred of custom and example, born of the imitation of bad models and the cultivation of false personal ideals." That these may have added something to our stock of versatility, but nothing to our thoroughness or the sum-total of our real achievements, seems quite certain. The quiet habits of study, the methods of examination, the experiences that ripen into clinical wisdom and the broad conceptions of certain fundamental scientific truths so indispensable to the working program of the conscientious clinicians of yesterday are rejected, put into the discard, by the great mass of physicians of to-day. They seem to feel that they must master the discoveries in the science of medicine made in their own time, in their own way. And so the days find them wading up to their knees in the problems of the laboratory and up to their necks in the mysteries of research. The evenings are spent in dutiful attendance at the meetings of the medical society, and the nights under an avalanche of medical journals. There is nothing wholly disadvantageous in a schedule so comprehensive as this, but it carries its own penalties, and they are not few.

On the side of our everyday personal use of the microscope and test tube, for example, there is a lamentable show of indifference, due quite as much to our habit of haste as our slothfulness. In either instance it has brought, together with the growing burden and complexity of clinical diagnosis, increasing popularity to the organized clinical laboratory. This sort of institution, now come to stay, is entrusted with the most elementary analyses and encouraged, nay urged, to suggest the final diagnosis of disease on the slender evidence of a single positive or negative finding. Especially has this fault grown to dignified proportions in serologic work, where the temptation is always great to confine the clinical diagnosis to the test tube. A not dissimilar tendency is shown in the scant personal study of radiograms. I am sure that much unreliable radiologic opinion is vouchsafed on the strength of the hurried reading of a single Roentgen plate, often to the embarrassment of the radiologist and clinician, and to the detriment of the patient. In fact, it is to the discredit of our teachings in recent years that clinical medicine has availed itself of so much help from the methods of the laboratory. I would not be misunderstood as to the position and function of the approved general clinical laboratory, with a clearly defined policy of its limits in matters of interpretation. For whosoever has knowledge of the very great technical difficulties encountered in modern tests, to say nothing of their hidden philosophy, is sure to give to the dependable laboratory both material and moral support. But I fear for the general practitioner whose innocent lapses have led to the establishment of highly commercialized laboratories, and whose alliances in this direction are not always happy ones. At least, one's confidence in these institutions is not particularly strengthened by their announcements that for a reasonable fee one gets the best messenger service, the neatest specimen containers, the most perfect syringes, all loaded and ready for action, in rooms set aside especially for treatment purposes. Nor is it particularly gratifying to know that there are urinalysis mills that grind out monthly reports on urine on the theory that the albumin discovered in time, and always indicative, to them, of Bright's disease, will increase the life expectancy of every individual so afflicted.

As an instance of over-tension of very doubtful value, I would cite the bread and butter physician's restless pursuit of research. Now, research, I take it, is an organic part of medical science, a field open to workers with a capacity to create and discover. It is, and should be, the lifework of students, a few of whom may become attached to university clinics or clinical research hospitals, whose fitness is determined by a certain cast of mind, reinforced with the years of special training. In the truest sense of the term it is a non-clinical department of medicine in which the observational faculty, the chief asset of the physician, plays a subordinate rôle. To its votaries it may bring fame, seldom fortune. Obviously, then, the motive for the many physicians apprenticed to pseudo-research is not to be apprehended in any pecuniary gain. Aside from the genuine fascination which the creative faculty is sure to have for some men of academic type, there comes to my mind the thought that the many amateurs in research recruited from the heterogeneous mass of clinicians are attracted to it by the glamour of the name. Dilettantism is the inevitable result, to be deplored if not despised. And if proof of its prevalence were needed, I might quote a brilliant worker in the field of internal secretions who recently told me that in one year some twenty-four hundred contributions had been made to the literaure of the polyglandular disorders, but he discreetly refrained from any comment, even bordering on their real value. Conceding that most of the work done in the name of research is corroborative rather than creative, the regret lies not so much in that plain fact as in the reflection that it diverts physicians from the paths of the clinic, paths quite as congenial, and, in respect of their talents and equipment, infinitely more promising.

Of the medical society as a nocturnal outlet for our intensity, as a forum in which the practitioner at the end of a busy day may imbibe and impart knowledge, I would say a word. The founders of every medical society who build "for that unity and friendship which is essential to the dignity and usefulness of the profession" have our unbounded respect and admiration. But I ask myself how many societies are necessary to the growth of such an ideal? The theory of the humanizing, socializing value of medical gatherings stands approved, but how many such gatherings does it take to make one human and social? The educational value of the special society is conceded, but I am interested to know how many special societies are essential to keep us well educated? The cultural advantage of the academy is apparent, yet how many academies will it take to keep us cultured? The society "that is a clearing-house in which every physician of the district is to receive his intellectual rating, and in which he finds out his professional assets and liabilities," has a perfectly good claim to existence, but does it require more than one good society to take a stock inventory of any physician? The society conceived in the spirit of fraternity but nursed in an atmosphere of politics is not without merit, but I cogitate on the number it will take to transform me from one kind of a genuine friend into another kind, perhaps not so genuine. Finally, not knowing the answer in all cases, the decision is made to join them all. I be-

come a meeting fan. Nightly attendance gets me brainfagged and befuddled, puts me in a state of mental disequilibrium. All mixed up together in my mind are the men I have seen and the things I have heard. Under the conditions nervous tension is accelerated, but vision impaired and comprehension dulled. One may be likened to the motor with an engine racing at top speed and the clutch thrown out; the power is there to make us vibrate, but not to let us move. This medical society madness instead of manifesting itself as a phase of the theory of relaxation, as indeed, it should, presents itself as a symptom of the gospel of intensive work, which it should not. There probably will be no escape from it until a new type of physician shall arise, whose function it will be to give us by night, as well as by day, refreshing rather than exhausting exercise for the mind, and at all times more ease.

Bearing on our habits of stress, witness, in conclusion, the making of our ephemeral literature and our anything but ephemeral manner of cultivating it. As the designation would tend to imply, I have not in mind the truly great books that we turn to in pleasant leisure; nor the medical classics we cherish for their inspiration; nor even the monographs that have value for their solid contents and the systems for their completeness. I think of the stuff that Osler once aptly called "bastard literature," put out in tons to advertise the nostrums of commercial houses, and never entirely failing of its purpose to impress a credulous profession and victimize a gullible public. When we have read as much of that as comes to our notice, we reach for the textbooks announced by even respectable publishers as authoritative, to find them too often perpetrated by medical scribes not yet dry behind the ears in clinical experience, to say nothing of their erudition. Next we turn to the increasing bulk of journals in all departments of medicine, written in all languages and coming from all quarters of the earth. Particularly delectable are the many abstract journals, *Ergebnisse, Centralblätter*, and the like. They aim to make us genuinely cosmopolitan, and would succeed admirably but for the unfortunate way we have of seldom consulting the abstracted matter in its original form. And just before the hour of retiring we take up Archives, Bulletins, Transactions, Reports, that deal with problems so entirely beyond our understanding that we can only look wise or bored and appease our vanity by cutting the pages, but not necessarily turning them. Of course, there are men with nimble minds who read avidly and without harm to their poise and perspective, but these aside, I find it rather difficult to determine which readers as a class are deserving of the more pity, the ones deeply submerged in the world's best medical thought, with minds so overtaxed and demoralized as to incapacitate them for independent thinking, or those remaining much on the cover page, with a fickle taste for the pabulum underneath, and their minds never even given to contemplation. It may prove difficult to estimate how much or how little a man can read with comfort or profit to himself, but Professor Minot expressed a wholesome point of view when he remarked, "Let us never forget that in contemporary education the moribund ideal is slavery to books; the nascent ideal mastery of facts!" One step in our emancipation from such slavery may be realized if we maintain a healthy skepticism toward every advertised book and periodical that comes from the medical press. Another, when we ourselves possess some higher wisdom in a branch of medicine, and learn to distinguish between the creators and compilers, the producers and popularizers. Still another, when our book reviewers turn honest and give us their real version of a work instead of testimonials of affection and esteem for the writer, with a few platitudes and stereotyped phrases thrown in for good measure. Such are a few of the points expressive of over-tension which it has seemed worth while for me on this occasion to bring to your attention. In doing so I have sought to avoid the critical spirit that craves expression in either the carping censure of the Philistine or the drastic tone of the Reformer. If I have not succeeded, it is because the task requires more scholarship and a more academic mood than it is my privilege to own.

If, however, we are agreed as to the main facts, we may occupy ourselves for a moment with the remedy. It has been suggested that the gravitation of the big problems of disease toward the large scientifically conducted hospitals, and the concentration of new discoveries to the "institutes" will relieve the medical body politic of this annoying degree of ataxia; that the better cooperation between the scientific investigator and practitioner will reduce the sum of misguided efforts and consequent stress. I am sanguine enough to think it may, but only in small part. Our clinician will still have his rightful and busy place. If there are any who think of the practitioner and the clinic as figures of the past, I commend the address by Mackenzie on "The Teaching of Clinical Medicine." In speaking of advances in our knowledge of diseases of the heart, he says: "The inception of all this work, the carrying out of the principal investigation and the great bulk of the discoveries were due to general practitioners, unhelped by any of the hospital and laboratory contrivances which are considered essential to research." Far from having his usefulness curtailed, far from becoming the "vestigeal remnant of a past state of things," the practitioner will return to the halls of the clinic, to the examination of the man. There the tasks, however, must be met with a new working ideal, disburthened of hurry, anxiety, and unrest. Just as the money ideal in our profession is undergoing change, and it is no longer the size of the income, but the academic rank of the physician that will give prestige, so will the working ideal have to change. Calm methods will set a new fashion for calm, and even though the number of practitioners so disposed will at first be few, their example will encourage imitation of the habits that in the end will rank as good. There must be a show of far greater nonchalance toward the "cult of the passing hour," and a larger regard for fixed and abiding truths. The argument gathers force when put in the words of the essayist who said, "Not discovery, but rediscovery, is the key; make the comparison in what field you please; contrast the kaleidoscopic glimpses of travel with the reperusal day by day of a familiar landscape, the fluttering from one new book to another, with the life-probing problem of some mighty classic, the patter of shifting acquaintance with the slow, calm pace of proved friendships, the caprices of unfixed passion with the loves that embrace a lifetime: The attestation to the worth of permanence is universal." In a better inward self-adjustment—the secret lies.

In the time remaining the part of my theme relating to the public can only be touched upon in its very minor aspects, and not without some misgiving.

It is as a healing art that medicine has always

enjoyed the confidence, such as it is, of mankind. Its noble ancestry, its honorable lineage, its rôle in Egyptian and Greek culture; its prestige under Hippocrates, and five hundred years later under Galen; its position during the dreary, benighted centuries that faded into the dawn that gave us Vesalius and Paré, may have occupied the attention of scholars and historians, but had no interest for the mass of the people. Not until we scan the events and activities of the eighteenth and nineteenth centuries do we find the lay mind much concerned about our achievements, and then only in respect to our triumphs over human suffering. The possibilities of alleviating physical pain have always appealed to the imagination of man, and in more recent years those indispensable accessories to the surgeon's craft, the anesthetic, the anodyne, and the principles of asepsis, have won both his approval and admiration. Of that great blessing rained upon humanity by the control of epidemic disease little need be said. With smallpox bridled, yellow fever practically extinct, typhoid fever reduced, diphtheria robbed of its terrors, meningitis and malaria controlled, tuberculosis better understood, bubonic plague and tropical diseases intelligently combated and cancer intensively studied—the world has indeed become a better place to live in. And yet—as the scope of our science has enlarged, as its spirit has deepened, as our gifts to humanity have been more numerous and far-reaching, we observe the curious and ofttimes painful phenomena that our efforts are not always less hampered by the public and the judgment passed upon us not always less malign. There are thoughtful persons who seem reverently disposed toward the memories of Carroll and Lazear, whose acts of heroism in the form of self-inoculation with the parasite of yellow fever were performed all for humanity's sake. Then there are others—I shall not call them unthinking persons, delusional would be more to the point, who, in larger social groups, under the guise of sanity, capitalize themselves as antivaccinationists and antivivisectionists. The latter especially are even now spasmodically engaged in pseudo-formidable campaigns against the very types of animal experimentation that have resulted in the greatest benefactions to man. Except for the genuine regret we feel at having to take our perfectly good and valuable time in refuting their statements, these coddlers of dogs and other household pets are undeserving of serious attention from the self-respecting gentlemen of the profession. If it be argued that the righteousness of their cause is to be seen in their increasing numbers, the fact should not be lost sight of that here, as in all similar anti-movements, the factor of sheer social imitation is responsible for the gain.

Moreover, I think we need concern ourselves but little when the great and more often the near-great of other walks of life take issue with us over problems, the nature of which they cannot know, but presume to attack on a theory of common-sense. I have in mind the recent utterances of a "great personality" in American life on the question of eugenics. He grows either exasperated or melancholy when he sees good able men devoting their time to fighting shadows. Contrasted with this remark I quote a sentence from a distinguished scholar in genetic science. In an address on heredity, delivered at the Seventeenth International Congress of Medicine, Professor Bateson said: "It is this knowledge which has given to genetic science a position paramount among the branches of physiology, showing that in accurate genetic analysis a means is given out not merely of elucidating the interrelations of parent and offspring—the immediate subject of our investigation—but of contributing also to a right interpretation of various special problems of pathology and authropology, perhaps, also, to a true understanding of the course of human history and certainly to the direction and control of the destinies of mankind."

The harm done by the ill-advised meddling of dilettantes in questions of the kind and importance of genetics is best illustrated by the eugenic marriage laws now on the legislative books of some of our States as the direct result of a campaign of poularized eugenics. More eloquently and conservatively than anything I could say in regret of such previousness, has been said by Bateson in reference to the so-called "Mental Deficiency Bill." He remarks: "This bill we recognize as, in principle, a wise beginning of reform, but, on the other hand, we cannot hear without disquietude of the violent measures that are being adopted in certain parts of the United States with similar objects. It is one thing to check the reproduction of hopeless defectives, but another to organize a wholesome tampering with the structure of the population, such as will follow if any marriage not regarded by officials as eugenic is liable to prohibition. This measure, we are told, is actually proposed in certain States. Nothing yet ascertained by genetic science justifies such a course, and we may well wonder how genius and the arts will fare in a community constructed according to the ideals of State Legislatures." In the light of this commentary, may we not with much justice ask a well-meaning yet too eager public to restrain itself from efforts at the consummation of principles that at present give nothing more than promise? If its enthusiasm for the work of our profession must find an outlet, may it not be more profitably directed at the education of the commonwealth, still so far behind our great philanthropists in initiative, and generosity? Let its energies be directed toward the suppression of organized opposition to the advancement of science; let them learn the significance of the labors of our Carrolls and Reeds, and Gorgases. Let our public feel the impulse not alone to give these men and others of their kind honorable mention and medals, but ample pensions for themselves and their posterity; and, finally, let it give to all the truly great of earth not only pedestals in a National Hall of Fame but abiding places in our national consciousness.

104 South Michigan Avenue.

A PLEA FOR A RESEARCH INTO THE POSSIBILITY OF THE CURE OF DEMENTIA PRECOX BY THE USE OF SERUM CONTAINING THE DEFENSIVE FERMENT.

By BAYARD HOLMES, M.D.,

CHICAGO.

Immunity is a result of a defensive ferment reaction on the part of the organism. It is brought about in some manner by the blood in its effort to excrete the toxic albumin by the production of a catabolizing ferment which acts upon the toxic albumin to produce an excretable peptone, polypeptone, and aminoacid out of each individual molecule of albumin. Each toxic albumin is molecularly

individual and unlike any other albumin in its molecular construction and arrangement. The formula of albumin is ordinarily written $C_{720}H_{1134}N_{218}S_5O_{248}$ and its molecular weight is given as anywhere from 15,000 to 16,750. It is at once obvious that the possible combinations of so many elements into a single molecule gives abundant room for an almost infinite number of distinct and separate albumins that differ in structure, form, and function from every other of the albumin molecules. Even with only twenty atoms the possible combinations as shown by Abderhalden require nineteen figures for their expression, namely, 2,432,902,008,176,640,000.

The ferment which arises in the body as the result of poisoning with a toxic albumin is perfectly adapted to the catabolizing or wrecking of that albumin molecule and that alone, just as the key of a Yale lock is adapted to throw the bolt of its own lock and no other. In another respect also the ferment resembles the key of a lock in that the key is not used up by the process of unlocking and is perfectly good for the unlocking of any number of identical locks. So is the ferment adapted to catabolize or wreck any number of identical albumin molecules without producing any change or loss of energy in itself. This catabolizing process is necessary to the solution, destruction, and excretion of the toxic albumin and it is nature's primeval remedy. It began in the lowest forms of unicellular life. All albumin molecules are large and colloid, that is to say, they are unable to pass through a dializing membrane or escape from the blood through the secreting and excreting apparatuses of the body. The wrecking of the toxic albumin molecule is the prime function of the ferment; such ferments, however, which have been called defensive ferments by Abderhalden, remain for a long time in the body of the organism in which they are once produced. The end products of this catabolizing process of the albumin molecule are crystalline. They are usually reckoned as peptones, polypeptones, and aminoacids and they are in condition of solution which makes them easily excreted and easily passed through the dialyzer.

Each defensive ferment has the power of wrecking one particular albumin molecule and do this over and over again, but most remarkable of all is the fact that it can do this as well outside the body in a test tube as in the body in the circulating blood and tissues where it is produced. On this fact is based the Abderhalden reaction.

These defensive ferments are themselves albuminous in structure and colloid in form. On this account they do not pass through the dialyzer and probably for the very same reason they remain a long time in the body of the organism or individual where they were generated even after all the toxic albumin which roused the blood to their production has long been excreted and out of the way.

Another remarkable phenomena has lately been demonstrated by the method of Abderhalden. It has been shown quite conclusively that a defensive ferment produced in the blood of one animal and recognizable in the blood serum of that animal by the Abderhalden reaction may be transferred to the blood of a second animal by the injection of a small portion of the serum of the blood of the first animal. It can now be transferred from the second animal where it is recognizable by the Abderhalden reaction into a third animal with the same result and so on almost indefinitely. These experiments have been performed by Abderhalden and Grigorescu by Arno Lampe and A. Fauser* of Stuttgart and the ferments remained in the blood and could be recognized there as long as the animals had been kept under observation. These researches seem so suggestive to Fauser, who used the blood of dementia precox cases and injected it into rabbits, that he felt bound to report the result of his observations without further delay. This phenomenon has been termed the passive transmission of defensive ferments and it offers the greatest therapeutic advantage both by eliminating other toxic or disease-bearing qualities which the blood of the patient might carry and having ready at all times an abundance of ferment containing blood to be used on the spot or safely transferred to almost any distance. Fauser recognized the defensive ferments against the albumin of testicle or ovaries, of thyroid and of brain cortex in the blood of his dementia precox patients, and after the injection into the passive animals even in the second and third stages of transmission the same ferments were recognized for a long time and without any apparent diminution in quantity and potency in the serum of the blood of these passive animals.

It has occurred to me, as it has doubtless occurred to many others, that recovery from dementia precox which we believe to be a toxemia depends upon the production in the patient's blood of a defensive ferment against the toxic albumin of the primary disease. It is my firm conviction that dementia precox now, with the help of the Abderhalden reaction, so uniformly recognized by the evidences of pluriglandular dysfunction, is the clinical manifestation of a toxemia by an unknown toxic albumin of a metabolic, parasitic, or other unknown origin. It is a toxemia like that of general paresis, the source of which we have at last discovered in the toxic albumin produced in the tissues of the body by the *Spirochæta pallida*. Very promptly after this discovery a remedy has been contrived in the use of neosalvarsan serum. The toxic albumin which initiates the toxemia of dementia precox and is followed by a train of pluriglandular dystrophies is the great psychiatric x of the present day. The search for the defensive ferment against this x is an object worthy the efforts of an army of research men. This defensive ferment is responsible for the waking up and temporary improvement of many cases of dementia precox and for the recovery of a few. The reason that so few remain permanently cured appears to depend upon the rapid disappearance of this ferment from the body. When it is gone the patient relapses and becomes clouded and shut in by the toxemia of the disease.

Let us suppose that we have a case of recovered dementia precox or one in those brilliant moments of improvement that sometimes last for weeks and months. We have made the Abderhalden reactions and found that the serum of our patient's blood contains defensive ferments against the albumin of the genital glands of his sex, the thyroid, and the cerebral cortex (g, t, ct). Now let us inject a few cubic centimeters of the serum of the blood of this patient into the pleural cavity, the peritoneal cavity, or the subcutaneous tissues of a large animal, a horse, a goat, a sheep, or a dog. According to the experience of Abderhalden and Grigorescu, of Lampe and Fauser, we have a right to expect

*Fauser, A.: *Münchener medizinische Wochenschrift*, July 21, 1914. Vol. LXI, pp. 1620-1621.

that the serum of the blood of this horse or other animal will after a few days furnish ferment-containing serum against the human albumins *g, t, et,* and contain also any other ferments that were in our patient's blood that we had failed to recognize.

Cases of dementia precox do recover, and although the recovery may not be complete and since our experience shows that they are not apt to be permanent, it would be very desirable to maintain in a passive animal, such as the horse, a stock of ferment-bearing serum against the hypothetical and problematical toxic albumin *x*. In my own experience I now believe I could demonstrate two cases of recovered dementia precox. From each of these I would propose to remove a portion of blood sufficient for a complete Abderhalden study and also for the serum necessary for the injection of one or two animals. The first portion of the serum would be tried out in the dialyzers against the various albumins, fundaments, or *Substrate* in the laboratory. The second portion of the serum should be injected into the horse; the third portion into the goat or sheep or some other animal.

According to all analogy these passive animals would furnish blood in a short time in which we could recognize the defensive ferments found by the previous examination in the blood of the recovered patient, and presumably there would be remaining in the blood unrecognized by us all the other ferments which we had failed to recognize in the blood of our patient for the lack of the necessary fundaments, especially the fundament *x*.

Having made this demonstration the serum of the blood of the horse or other animal should be tried out against the disease by injecting suitable quantities of the horse serum bearing the defensive ferment against *x* into such patients suffering from dementia precox as furnished blood that gave a reaction similar to the reaction of the recovered patient from whom the horse had received the primary injection.

Our present knowledge of immunity and anaphylaxis is sufficient to guide us in the safe administration of such horse serum for therapeutic purposes. Doubtless experiments would be necessary to determine the dose and its frequency, but we fortunately have a guide in the presence of the secondary ferments, namely, those against the genital glands, the thyroids, and the brain, for the administration of the unrecognizable ferment against the toxic albumin *x* upon the presence of which we place our hopes of betterment or cure.

Such an undertaking as I have here suggested is entirely beyond the resources and facilities of any private individual, however devoted he may be to the needs of the suffering hundred thousand of helpless dementia precox patients. Such a research requires large laboratory facilities, well-trained and optimistic laboratory research men, and a suitable biological farm where the animals may be kept under definite and favorable conditions. This research requires the cooperation between a large number of workers with experienced, optimistic clinical psychiatrists.

Nerve Transplantation in Laryngeal Paralysis.—G. Serafini and O. Uffreduzzi have demonstrated in animal experiments that it is possible to restore functional power to the distal segment of a severed superior laryngeal nerve by transplanting the free end of this segment to the pneumogastric nerve at the level of the original injury.—*Il Policlinico.*

THE RELATION OF GYNECOLOGY AND UROLOGY TO GENERAL SURGERY.*

By HOWARD LILIENTHAL, M.D.,

NEW YORK.

ATTENDING SURGEON MT. SINAI HOSPITAL, VISITING SURGEON BELLEVUE HOSPITAL.

In the presence of any of the strictly clinical branches of medicine success is measured in terms of the percentage of cure or relief. That this statement may be perverted by sophistry does not make it any the less true. A novice who has successfully performed two nephrectomies may proudly announce 100 per cent. of cures, while his more experienced colleague must acknowledge failure in say six of his first hundred cases. Yet, other things equal, the average individual would probably choose to be the hundred and first patient rather than the third.

For the purpose of this discussion we shall adhere to the consideration of urology and gynecology in their relation to their parent tree, surgery—and I believe that no one here to-night will dispute the fact that the connection is quite as intimate as my metaphor indicates.

Surgery is but a branch of Medicine, and like all other divisions of the profession, it begins with theory and principles. No matter what subdivision is to be later followed, these must first be mastered.

The next step is the study of what may be called *practice;* the learning of technical methods and details as applied to conditions as they are supposed to exist.

Last comes *experience*, that lifelong repetition in endless variety of the application of theory and practice to individual cases.

Early in a man's career he will probably discover a growing proficiency in the treatment of those cases which come to him in the greatest numbers, the patients being referred by others who have been relieved. This will naturally lead to more work and continual improvement in the same lines so that almost before he knows it he has begun to specialize.

Further study under the direction of a Master will now complete the normal evolution of the specialist. And one who has passed with credit through these various stages will never become narrow, no matter how closely he confines himself to his chosen calling.

It seems to be that there is no valid reason why a general surgeon should not practise gynecology and urology, provided he honestly feels that he can do the work required of him *as well as it can be done by the average gynecologist or urologist.* There are no flag-signals to warn him back where the ureter crosses the pelvic brim. If he is a true surgeon he is not only familiar with the anatomy and physiology of the part where he is operating, but he will have a working knowledge of the neighboring regions which he may be forced to invade.

Also, one who has become a specialist by the normal evolution which I have described may legitimately continue to practise surgery in general and to keep abreast of its progress. Such a man should certainly not be looked upon askance merely because though known as a specialist he chooses a wider scope.

But now let us look at another side of the question and consider the claims of a specialist who has had little experience in general surgery or even of

*Read before the Medical Society of the County of New York at its regular meeting, October 26, 1914.

one who though broadly trained has for years stuck close to his own particular line, not keeping up with the progress outside his own path. Here I think we must consider gynecology and urology separately.

First, Gynecology. This is not only a division of general surgery, but its boundaries are so vague that it appears very doubtful whether it is essential to have any special knowledge or attribute not possessed by all educated surgeons. In the non-operative part of the work, perhaps, a technique and diagnostic skill may be developed as a result of daily and long continued practice; but this is aside from the matter of gynecological surgery, and it can quite as easily be acquired by practitioners not trained at the operating table.

Gynecology is no more separate from surgery than is kelology, the science of hernia, or omphalology, the science of the navel. It merely takes in a larger region of the body.

In order to make intensive study possible, gynecology may be permitted to exist as a distinct service in a hospital just as diseases of the chest or of the stomach may be assigned to a group of men who are interested in these subjects.

With urology the case is somewhat different. This may be roughly divided into what I may call minor and major urology. The term *minor* being used for want of something better and not to signify a matter of little importance.

A surgeon who has not perfected himseslf in the technique of observation and operation with cystoscope and urethroscope would be a loser if with insufficient preparation he were to attempt this part of urological work. One may have taken a so-called "course" in cystoscopy, for example, and he may have catheterized a few ureters. Then comes a case of granular cystitis in which kidney observations are important. The problem of finding and catheterizing the ureters in such a case is not so easy and may tax the patience and the eye and hand of the elect.

To the occasional cystoscopist such an experience will bring nothing but embarrassment and humiliation. But, on the other hand the so-called pure urologist who ventures without ample preparation into the domain of major surgery is liable to feel in addition to mere embarrassment the qualms of conscienece which come from the knowledge of insufficient preparation and the fear that an unsatisfactory or even a fatal result might not have followed the efforts of one more schooled than himself.

Surgery has become far too big for any man to know it all, and so specialism is inevitable and as proficiency is attained in higher and higher degree we shall probably see more and more differentiation.

That portion of genitourinary surgery which deals with the local treatment of the urethra, the bladder and its appendages, and the ureters and kidneys may be designated as minor urology. And there should be included certain operative procedures seldom requiring general anesthesia. As thus described, urology may be regarded as a legitimate specialty for the prosecution of which a great surgical experience is not necessary. If a trained surgeon has the inclination and opportunity to add technical urology to his accomplishments there is surely no reason why he should not do so. But if after years of exclusive specialism he takes once more upon himself the responsibility of a major operation let him be sure that the march of progress has not left him too far in the rear.

Operative surgery in all its branches is an art and the surgeon has the feelings and sometimes the temperament of an artist. The personal element is a strong one. He is not unaffected by adulation, and, alas, with all his virtues he is prone to small vices akin to envy and jealousy.

It may hurt his pride to admit to a patient that he needs help in arriving at a diagnosis or in carrying out a treatment; yet the man of noble spirit, he who puts pettiness behind him, will welcome a division or even a shifting of responsibility when he does not feel the self-confidence so necessary to peace of mind.

The law expects a surgeon to possess and to exercise in every case what is known as "ordinary care and skill" and the interpretation of this goes farther and demands that the degree of skill required shall be judged by the standards of the community. Therefore more would be expected of a metropolitan surgeon than of a country practitioner who rarely operates. Work done in a special branch should be judged not by the work of a general man, but by the work of the average specialist—regardless of the standing of the operator himself.

But the best standard of all is that set by one's own knowledge of right and wrong. A conscientious surgeon will not treat any case unless he feels that he can do full justice.

Conclusions: 1. Operative gynecology should not be undertaken as a specialty except by those who have been fully trained in general surgery.

2. All general surgeons should be trained in gynecology.

3. Diagnostic or minor urology may be undertaken by any qualified physician.

4. Major urology is only for the fully trained surgeon.

48 East Seventy-fourth Street.

THE ASSOCIATION OF FOLLICULAR TONSILLITIS WITH ACUTE GASTRIC FEVER —A CLINICAL STUDY.

By LOUIS FISCHER, M.D.,

NEW YORK,

ATTENDING PHYSICIAN TO THE WILLARD PARKER HOSPITAL.

THE clinical association of tonsillitis with gastric fever is an every-day occurrence. It occurs so frequently that one may believe that the pathological condition is common to both—or that these conditions are interrelated.

The condition is seen in the infant as well as in the older child. It occurs as a sequence to a deranged stomach, following overfeeding or the feeding of food which cannot be properly assimilated.

An interesting feature is that while there are active symptoms of a deranged stomach, with fever, acetone breath, flatulence, colic, and usually constipation, there will usually be an accidental discovery of some pin-point tonsillitis involving the lacunæ of the tonsil. Cultures taken from the tonsil will show the presence of the staphylococcus—never the Klebs Loeffler nor the streptococcus. In some cases the *Micrococcus catarrhalis* is found. The cervical glands are never enlarged. The temperature is usually quite high, between 103° and 104°. There is seldom pain on swallowing or any evidence of disturbance in the throat.

Many of these cases subside without any local treatment. The throat manifestations improve just as soon as the gastric symptoms subside, so that one

is forced to believe that both conditions are one and the same infection.

When there is a recrudescence we again note the same symptoms, *to wit*, first: the general gastric disturbance in which pyrexia, acetone breath, meteorism, anorexia, and usually constipation exist. In addition thereto the local evidence of a benign follicular tonsillitis. I have seen such recurrence of both conditions several times in a year, and am forced to the conclusion that both manifestations are part and parcel of one and the same infection. Whether or not the bacterial infection originates in the mouth and tonsils first, is difficult to determine. It seems to me that the gastric derangement is responsible for the fever. The toxin lowers the vitality and permits the migration of the ever-present staphylococcus, *Bacterium coli*, or *Micrococcus catarrhalis* from the surface of the tonsil to the deeper structures and this in turn gives rise to the local evidences of the follicular type of tonsillitis.

What I wish to impress with this note is that the frequent occurrence of gastric fever demands a careful inspection of the tonsils and when such tonsils show evidence of hypertrophy they should be treated as diseased tissue which may be a focus for future malignant infections.

Loss of appetite, or rather a refusal to eat, will be noted; all symptoms pointing to a gastric derangement will be present, and still the predominating symptom will be the patches or follicles on the tonsils, causing pain on swallowing.

Too much importance cannot be placed on the *necessity for throat inspection in every child that refuses to eat.*

Cause—Hyperacidity.—An excess of hydrochloric acid is usually one of the causes of this condition, due to a functional disturbance of the stomach. As a rule such disturbance is solely due to improper food whereby stagnation occurs. Stagnation results in irritation and consequent inflammation.

In severe cases owing to the enlargement of the tonsils vomiting will occur. This vomiting is not gastric in origin but is due to the impinging of the tonsil on the pharynx, thereby irritating the pharyngeal wall with resultant nausea and vomiting.

Another important point is the noncontagious character of the throat trouble. Children even though they be in close or direct contact need not fear contagion.

Prognosis and Course.—The prognosis is good, children invariably recover. The course of the disease depends on the severity of the infection, but as a rule an attack subsides by the end of from three to six days.

Treatment.—An alkaline laxative such as a 3 to 5 grain dose of compound jalap powder should be given and repeated every three hours until a thorough evacuation has been produced. During this eliminative treatment water should be given liberally, but no food.

Locally, for the throat tincture of iodine diluted with an equal quantity of water should be applied once, with the aid of a cotton swab.

Food.—After the bowels have been thoroughly cleaned then chicken soup or milk from which the cream has been skimmed or weak tea may be permitted.

For the after-treatment one or two drops, depending on the age, of tincture of nux vomica may be given before meals.

155 West Eighty-fifth Street.

THE SEXUAL SIGNIFICANCE OF RECENT FASHIONS.

By EDWARD HUNTINGTON WILLIAMS, M.D.,

Los Angeles, Cal.

Formerly Associate Professor of Pathology, State University of Iowa; Physician in the New York State Hospital Service, etc.

Human wearing apparel has, of course, a very distinct sexual significance. And probably, were we able to trace the connection, we should find a very definite relationship existing between the prevailing fashions of any period and the maintenance of sexual balance in communities as a whole.

We are given a hint of this by the fact that whenever revolutionary methods of living, which influence sexual equilibrium, have taken place, there have been accompanying changes in fashions. These changes, if viewed in long perspective, show that with the steady progression toward higher civilization and culture, there has been tendency in the fashions of men's garments to become more practical, unattractive, and somber. At the same time there has been no corresponding change toward simplicity in woman's apparel. On the contrary, female costumes, at least during the last few years, have been tending decidedly toward suggestiveness rather than modesty.

The most revolutionary changes in methods of living that the world has ever seen have taken place during the last century, particularly during the last twenty-five years. Even in the last decade there have been pronounced changes. And during this last period there has been a peculiarly persistent tendency toward suggestiveness in the prevailing feminine fashions, without any corresponding change in male attire.

No one can doubt that the well dressed man of today, with the creased angularities of his garments concealing the last vestige of anatomical outline is a far less attractive animal sexually than the highly colored Colonial gallants of a century ago. Personal adornment was quite as much a masculine foible as a feminine frailty in Colonial days. But why, one may well ask, has woman continued to gratify her natural instinct to adorn, while her consort has retrograded in the opposite direction? Perhaps the answer may be found in the disturbed sexual equilibrium that has resulted from changed economic conditions, which in turn have influenced the peculiar twists in fashions.

The sexual influence of dress is a subtle one which stimulates by suggestion rather than by direct appeal. To be most effective there must always be a restraining element of modesty. This fact is likely to be overlooked by the courtesan, particularly the one whose wiles are waning and who strives to force attention by overstepping the bounds of decency. Her very frankness often defeats her purpose where veiled suggestion would have succeeded. Instinct and experience teach her that such is likely to be the result, to be sure; but stress of circumstances often force her into adopting methods not sanctioned by calm judgment.

The fashions in women's clothing that have prevailed for several years have shown a somewhat analogous tendency to over-frankness, or suggestiveness. But these fashions cannot be attributed to any deterioration in the attractiveness of women as a class. The very suggestion of such a thing is repugnant. Yet, as I shall point out in a moment, there is every reason to believe that at the present

time there is a pronounced disturbance in the civilized world's sexual equilibrium—an inequality in the supply and demand, if you please. And it is quite conceivable that the recent modes are one of the results.

The fashions to which I refer as having a decidedly suggestive tinge made their appearance about six years ago. At this time the hobble-skirt in only mildly suggestive form at first, made its appearance. On casual inspection these peculiarly inelegant creations appeared rather retiring than obtrusive, although they did give somewhat too much opportunity for exhibiting attractive pelvic symmetry and femoral curves. This unobtrusive quality obtained only during the static periods of the wearer, however. When she moved about, particularly when it became necessary for her to move quickly or attempt unusual altitudes, there was a decidedly suggestive clinging of cloth, with occasional revelations of hosiery, that made the costume far more suggestive than the older and more graceful full skirt.

Practicality, or convenience to the wearer, cannot be advanced as an excuse for this peculiar freak of fashion; for these costumes were neither convenient nor practical. And yet they persisted—persisted and withstood the supreme test of open ridicule by the entire male population. Moreover, the argument that the wearers were ignorant of the suggestiveness of their peculiar garments is untenable; for this feature of the hobble-skirt became the object of special comment and criticism in every walk of life, from gutter to pulpit. The answer to these criticisms was precise and unequivocal. Skirts were shortened, contracted, slit up the side (or front, or both) and made diaphanous in a manner that dispelled any doubt as to their meaning.

The frankness of this action, and the persistence of these fashions, offer pretty conclusive evidence that there is a sexual significance behind it all—an expression of sexual maladjustment as the result of the suddenly changed economic conditions of recent times. The nature of the sexual impulse as we now interpret it in the light of helpful frankness, Freudism, and studies of the internal secretions, suggests this.

The gist of these studies may be summarized in the general statement that the sexual impulse plays a tremendously important part in the physical and psychic life of every individual. That it is not a force which lies dormant to be conjured up at will, but one that is always acting, exerting a positive if frequently an intangible influence.

There is nothing novel in this conception. On the contrary it is as old as civilization itself—was an old theme long before the days of the phallic worshipers along the Nile. But until very recently there has been an inclination to avoid the facts. For a puritanical prudery has so dominated our Western civilization that anything like frank statements in print about sex questions have been tabooed except in certain ultra-scientific publications. Even in medical classrooms a frank discussion of the significance and influence of sexuality was frowned upon as indicating an "unwholesome tendency," if not actually a vicious taste. The dominance of the Puritan preacher was felt even in the realm of seekers for truth. But when studies of the internal secretions made it apparent that the sexual apparatus is an active factor in body metabolism, and that the sexual organs are something more than mere appendages for procreative purposes, the conception seems to have appealed to laymen with all the farce of novelty.

In point of fact the only really novel feature of the subject is the mystery of the internal secretion. There is certainly nothing new, to physicians at least, in the knowledge that the sexual apparatus influences many phases of metabolism and deportment at other times besides the transient periods of tumescence and detumescence. For there has always been a well defined impression that "all strong emotions, however non-sexual, tend to overflow into sexual channels," as Havelock Ellis concisely expresses it.

It requires no very great acumen to discern that the young woman who is disappointed in her love affair, and who plunges into the profession of nursing as a life work, is often governed largely by a sexual complex; or that the "settlement worker," unhappy in her marital relations and anxious to help other unfortunates, is transmuting sexual energy into channels that act as sexual equivalents. For it is pretty thoroughly appreciated that although sexual energy is a constantly accumulating force, it is a force that may be sublimated, or transmuted in one of a thousand ways besides that of actual sexual intercourse.

It should be borne in mind, however, that the effect upon the individual may be very different when the method of discharging accumulated sexual energy is other than the one designed by nature. Sublimation, transmutation, and so-called "sexual equivalents," are not actually the equivalents of normal coitus in their ultimate effects upon the system. And therefore we must regard as abnormal any method that relieves the accumulated sexual energy except the orthodox physiological one, whether that method take the form of religious ecstasy, homosexuality, or hurling bricks through British window-panes.

The important part, from our present point of view, is the fact that although the constantly accumulating sexual energy may be partially transmuted in various ways, this transmutation is usually incomplete. And, this being the case, we are pretty certain to find various indications of this disturbance of the normal sexual balance.

We know that any great change in mode of living is a disturbing factor to sexual equilibrium. Thus we find that as a race evolves from the primitive stage it departs in certain ways from the sexual habits of primitive life, which ways are in turn a departure from the still more primitive sexual life of the lower animals. Crowding people into cities undoubtedly influences their sexuality in something the same way that restraint and captivity affects the sexual instinct in animals.

In the last half century, particularly during the last twenty-five years, a revolutionary change in our modes of living has taken place—a tendency to abandon the countryside and huddle into cities. A somewhat similar change took place in ancient Greece and Rome, but these changes were comparatively slow. In America it has taken only a little more than the lapse of one generation to change from a nation in which something more than 90 per cent. of the people lived in the country, to one in which less than 50 per cent. are rural dwellers.

Yet even in Greece and Rome, where the changes in methods of living took place gradually with far better chance for sexual adjustment, there developed all manner of perversions, which may be attributed,

partly at least, to the enervating "cooping up" process. And it is inconceivable that our sudden changes are not producing maladjustments of a somewhat similar nature, directly or indirectly.

The most conspicuous direct effect of this sudden increase in the proportion of city dwellers is to lessen the number of marriages, and to postpone to a later period of life the marriages that do take place. Thus many men and women who would have married at twenty or twenty-three, a century ago, do not marry at all, or postpone marriage until considerably later in life. There is a difference in this time-element of at least five years. But during those five years there is no cessation of the sexual functions, which are ungratified in the natural way at this period of life—the very period at which the call for such gratification is most insistent.

Obviously the hardship entailed by this arrangement falls more heavily upon the women than upon the men. For a "double standard" does exist, and flourishes just as much now as ever before, with the net result that man is enabled to maintain his sexual adjustment, legitimately or otherwise, whereas woman cannot, or at least does not, do so to the same extent. So we see that the feature of city life which prevents or delays marriage, is an important factor in the accumulation of women's ungratified sexuality.

But this direct effect of city life upon sexual life is supplemented by others less direct, although quite as effective in actual results. Crowding into cities produces high-tension living, with the attendant results—"the general tendency to quick and sensitive reactions which marks all urban life under modern conditions." As an index to this we have the increasing army of neuropaths, psychopaths, and neurasthenics.

This heightened tension and increased sensitiveness unquestionably affects the sexual life of the individual and the community, but the effect is frequently precisely opposite in the two sexes. Thus in the male neurasthenic there is not only a tendency to impotency, but a distinct lessening of the sexual desire. In the female neurasthenic, however, there is not a corresponding loss of sexual desire, and, of course, no loss in potency. So we find that this condition, which has become a vital factor in modern communities, acts as a direct disturber of sexual balance because of its utterly different effect upon the two sexes.

In this connection, also, it should be remembered that we now have an increasingly high percentage of high-strung, nervous, active-minded men who are driven by engrossing business activities; while at the same time we have developed a correspondingly large class of nervous, idle women. High-tension business activities afford a means of sexual deflorescence which may act as a sexual equivalent. Idleness, on the other hand, tends to stimulate rather than depress the sexual desire. Or, stated in another way, idleness does not offer a means of taking care of the emotional overflow that seeps into sexual channels, but which would be sublimated by normal activity. So here again we find our modern methods of life disturbing the natural sexual balance by affording a means of sexual deflorescence in the male, without any corresponding means of deflorescence in the female.

Thus we see that our present mode of living, with crowded cities, strenuous business activities, and craving for excitement, tends to produce a distinctly altered condition in the country's sexual balance. It produces bacherlorhood and postpones the time of marriage several years, thus directly affecting the natural supply and normal demand; it produces an appreciably large class of men who are in effect impotents; and it lessens the natural sexual desire in men by the transmuting process of active mental effort.

Meanwhile there are no corresponding factors for reducing or transmuting the sexual accumulations of women. On the contrary, modern life tends to increase woman's impulse, but it reduces her chances of having this impulse gratified.

We find another evidence that we have gradually developed a condition of sexual unbalance which is largely in favor of the man and against the woman, if we compare the sexual habits of the lower animals and those of the races low down in the scale of evolution, with the sexual habits of the civilized races; and compare also some of the fashions and customs of past centuries with those of to-day. In the bird and animal world it is the male who must do the strenuous courting to arouse the ardor of his consort, and even then his success is directly dependent upon a definite and periodic physiological process taking place in the female.

A somewhat similar, although greatly modified condition exists in certain savage tribes, where the burden of courtship falls upon the male. In these tribes the male resorts to "parades, displays, dances, and mock combats" to arouse the ardor of the female, who still retains a vestige of the sexual instinct of the ancestral animal. Undoubtedly the periods of intensified sexual impulse are more pronounced, and correspond more closely with the periods of ovarian activity in the savage woman than in her civilized sister. But as we advance upward in the scale of civilization we find that a period of fairly constant sexual desire supplants one in which there are periods of complete indifference which coincide with the periods of ovarian dormancy in the lower animals. The periodic physiological time of fecundity still persists, to be sure, but this period has relatively slight effect upon sexual desire or gratification. Indeed, it is a common observation that there may be no relation whatever between actual fertility and sexual desire in civilized women, since women who are absolutely sterile on account of rudimentary uterine and ovarian development frequently have perfectly normal sexual impulses. Even nymphomania has been known to exist in women with undeveloped sexual appendages.

This last is, of course, an example of an abnormality that is the product of civilization in general, not merely the result of recent changes. But when we compare the prevailing fashions of Colonial days with those of the present time, we find evidence of influences of a more subtle nature. The gay colored Colonial found it advisable, perhaps necessary, to display his bright plumage to arouse the ardor of his consort. And this suggests that the sexual balance in Colonial communities was at a point of adjustment where the woman still needed somewhat more arousing than her modern descendant.

Be that as it may, it is certain that she was more active physically than the modern woman, of more stable nervous adjustment, and sufficiently occupied with normal household duties to afford a natural outlet for any superfluous accumulation of ungratified sexual impulses. The church also afforded the Colonial dame a means of sexual deflorescence that is denied the modern woman in these days of lukewarm belief, skepticism, and crumbling creeds.

The change in mode of life and mental attitude has been quite as pronounced in the case of men. The men of today are absorbed by strenuous business transactions, have become less athletic as a class, more high strung, and more addicted to bachelorhood. They have also gradually discarded garments whose chief asset was display, for those of somber, unattractive comfort and utility.

Meanwhile a change in many ways precisely opposite has been taking place in women. Idleness has supplanted housewifely activity; motherhood has become less and less a part of normal womanhood, and the physiological events immediately preceding it have become almost pathological; and higher senses have been cultivated to the extent of heightening nervous tension and increasing nervous instability. But, although some of these changes correspond closely with those that have taken place in men, there has been no corresponding tendency to modest sobriety in dress. On the contrary woman has been consistently inclining in the opposite direction. And recently this inclination has taken a somewhat startling turn toward unusual suggestiveness.

It is quite possible, therefore, since there are so many evidences that sexual balance is being disturbed by our rapidly changing civilization that these unusual fashions are an indication of this disturbed equilibrium. Possibly the hobble and diaphanous skirt, and exposed hosiery, are simply signals of distress—protests against the discrimination which modern customs and the double standard have instituted against the entire sex.

With this thought in mind one is led to wonder whether, after all, the sudden wave of desire among certain women for political equality is not really a mistaken interpretation of a desire for sexual equality. And to question whether the basis of all the recent movements and fashions—militantism, political equality, and suggestive skirts—is not the element of sexual unbalance asserting itself in one way or another according to the temperamental peculiarities of the individual. And possibly the fact that militant women are rarely the hobble-skirted ones, and hobble-skirted ones seldom militants, if subjected to careful analysis, would reveal that each is simply a manifestation of the same ungratified primitive instinct expressed in such radically different ways.

In any event, since men have been the controlling factors, the blame for both conditions may justly be laid at their doors. But all this is changing. Woman is coming into her own—or what she believes to be her own. And when this Utopian period arrives perhaps we shall see a restoration of sexual equilibrium. Possibly this will be accomplished by the distinctly progressive method of abolishing the "double standard"—not in the orthodox way suggested by male reformers, but by one precisely opposite in character.

609 Exchange Building.

Chronic Hemorrhagic Prepatellar Bursitis.—Giuseppe Campora reports a case of this condition which is not an exceedingly rare one. The formation is classified with the traumatic hygromata of which there are three types: the serous, the hemorrhagic, and the proliferating. The first and the last are the result of slight repeated traumata, while the hemorrhagic type is usually the sequence of a single traumatism. The wall of the hemorrhagic bursitis may be from a few millimeters to two centimeters in thickness. The prognosis is good provided the growth is treated as a simple chronic inflammatory tumor.—*La Riforma Medica.*

FACE TO FACE.

By WILLIAM P. CUNNINGHAM, A.M., M.D.,

NEW YORK.

ASSISTANT PHYSICIAN HARLEM HOSPITAL, DERMATOLOGICAL DEPARTMENT; CLINICAL ASSISTANT, NEW YORK SKIN AND CANCER HOSPITAL.

The human countenance has been variously idealized as the "index of the mind," "the mirror of the soul," "the chart of the emotions," "the portrait of the character," and sundry other beautiful conceptions which the poetic imagination has conjured up. By purely muscular effort, by the play and interplay of the delicate elements of its wonderful mechanism, it can faithfully delineate those purely psychical emanations which we denominate anger, fear, hope, pleasure, pity, and sorrow, and the numerous shades and gradations, thereof. Dulness, vivacity, candor, deceit, purity, and sensuality leave their imprint in the upbuilding of the individual countenance. It can transmit thought without the interposition of a spoken word. Asymmetry of development indicates degeneracy. This does not apply to what we style "homeliness," which may be associated with pronounced brilliancy of intellect and sweetness of disposition, but a want of correspondence between the two sides of the face. Cynics have emphasized the faculty possessed by the human face of repressing or counterfeiting emotions. This has come within the experience of every one, for deceit is no uncommon quality. Again, aside from the mischievous desire to mislead, it is considered a mark of virility and sturdy character to control these outbursts. Hence many men, and women, too, because of the usages of their class, pretend to an absence of emotion which they possess in as marked a degree as their more volatile fellow creatures. Betrayal of fear is considered disgraceful, stolid indifference to pain the badge of gentility. But in most ordinary mortals pain will be read on the countenance with perfect facility, and even the proud-spirited stoics reveal to the practised eye of the physician the secret they are striving to suppress.

Expert observers can often locate pain by a shade of difference in the expression. The contracted brow of headache is a familiar phenomenon. The pursed lips of abdominal distress are usually construed aright. The fixed visage and staring eye of precordial agony are unmistakable. The intermittent facial contortions of neuralgic paroxysms are readily interpreted. The screwing up of the face on one side will indicate an aching molar. Associated with lacrymation and a drooping eyelid it is highly suggestive of iritis. The half-opened mouth, forward thrust of the chin, and dribbling saliva are characteristic of acute pharyngitis. The broad nose and gaping lips of adenoids call for no extended comment. The saddle nose of lues is immediately recognized. Puffiness over the antrum of Highmore will point to a complication in that cavity during an attack of coryza. Puffiness of the lower lids is universally conceded to be significant of nephritis. While not literally a part of the face, still the columnar neck of Hodgkin's disease becomes such a prominet feature of the patient's picture that it may be properly included here. Goiter, especially if associated with exophthalmos, is a conspicuous deformity. The expression of uneasiness and anxiety, so manifest in this distressing malady, should lead at once to the proper line of investigation. The dejection of melancholia, and

the vacuity of paresis contrast pointedly with the exaltation of paranoia. The yellow tint of hepatic jaundice, and the bronze of Addison's disease are very naturally first discovered on the face. The pallor of anemia and the greenish tinge of its congener, chlorosis, are noted particularly in the same situation.

The cyanosis of embarrased circulation and the flush of its feverish acceleration will first attract attention there. The malar glow of phthisis is in vivid contrast with the encompassing waxy pallor. The unilateral accentuation of the pneumonic blaze as indicative of the lung affected is a clinical truism. The dilated arterial twigs observed in the countenance of the beefy, portly, puffy bon vivant, are a pretty reliable indication of the condition of his general circulation, and of the likelihood of a crash from arteriosclerosis. The menopause, in the long train of its discomforts, produces no more distressing symptom than its almost incessant "hot flashes." A burning face, with a look of piteous appeal, and palpable nervous hypertension, make a picture of compelling clearness. Alternate flushing and paling are, in connection with other signs, indicative of meningitis. This has been somewhat aptly styled the "fugacious flush." A weeping eye, as already noted, may indicate an iritis. It may also be produced by keratitis, dacrocystitis (occlusion of the lacrymal duct), or an inverted lash. The peculiar "sore eyed" aspect of granular lids is becoming more and more infrequent in our communities, owing, no doubt, to the keen precautions of our emigration officers. But we have a pretty constant supply of blepharitis marginalis of the "scrofulous" variety. In connection with the subject of the eye it will be apropos to mention the contracted pupil and nictitation of the opium habitué, and the dilated pupil and exhilarated mien of his cocaine counterpart. The swollen grayish facies of chronic parenchymatous nephritis, and the yellow, rough, toad-like mask of myxedema are the most remarkable manifestations of these affections. The sallow, muddy hue of intestinal stasis (the so-called bilious state) is a matter of universal observation, as are the fishy eye and sodden bloat of chronic alcoholism. The cancerous cachexia is revealed by a peculiar earthy tinge. The "risus sardonicus" of septic peritonitis is happily rather difficult to illustrate today. It consists in a drawing of the upper lip tightly across the discolored teeth in a most appalling grin. It was common enough in the good old days, preceding the era of asepsis. Facial palsy may be indicative of a lesion within the cranium or without. The conduct of the upper eyelid under attempted muscular effort will immediately settle the doubt. If the eye cannot be completely closed we are dealing with an involvement of the nerve after its departure from the cranium, in other words, with a Bell's palsy, and the prognosis is good. If the eye can be closed we are dealing with an involvement of the nerve before its departure from the cranium, and the prognosis is decidedly worse. The oscillations of the head in paralysis agitans, ceasing when the patient fixes his gaze, are accompanied by a total lack of expression in a florid countenance. Facial spasm is frequent in chorea, tetanus, meningitis, epilepsy, tic, postapoplectic states and hysteria. Central or peripheral irritation of the facial nerve may be the cause. Facial hemiatrophy is so marked a trophoneurosis that it cannot possibly be overlooked.

The preceding enumeration of the general conditions reflected in the face is naturally an imperfect one, and apter illustrations may be suggested by every practitioner. But it is not intended to include every instance of the sort. Rather is it intended to point out the effectiveness of the face as a diagnostic chart whereon is traced the course to pursue in devious pathology. One class of general conditions has not been yet described in connection with their facial manifestations. These are the exanthemata. While in reality general conditions, their conspicuous symptoms are so decidedly cutaneous that the writer has determined to group them with the dermatoses. With one exception all of them are noted on the face. The exception is scarlet fever, which does not advance above the line of the jaws. But even here its very absence is of negative significance, because a high temperature, with an eruption affecting the body and sparing the face, would be indicative of scarlet fever. Measles shows itself unequivocally on the face. In fact, it is the face which supplies the peculiar combination of signs that establishes the diagnosis. The ocular suffusion, the coryza, and the crescentic grouping of the dark red macules, make an absolutely characteristic picture of the disease. Rubella, or German measles, will present a rosier eruption without the grouping and coryza, but with a cervical adenitis and moderate angina. The face is a favorite site for the outbreak of erysipelas, and the dusky red, infiltrated cheek, forehead, or nose, with a sharp line of demarcation, is rarely misunderstood. A recurrent red eruption of less intensity, but as sharp delineation on the nose and adjoining cheek, is due to infection within the nasal cavity. This is frequently and incorrectly denominated erysipeloid (the "oid" pronounced as two syllables), which latter condition occurs only on the hands of those who handle putrid meat. Varicella, with its umbilicated vesicles in various stages of development, always invades the face. It is of consequence only when it is liable to come in conflict with variola. This occurs only in adults and during smallpox scares. The differentiation is usually easy, if attention is paid to the general conditions and to the manner of progression. Varicella, to begin with, is associated with very trifling constitutional symptoms. Variola is marked by a very distressing preeruptive stage. In varicella the eruption comes out in successive crops, so that vesicles are discoverable in all degrees of development, beginning, mature, and receding. In variola the lesions are all of one age. In varicella there is a haphazard scattering of the lesions over the face and scalp. In variola there is an evident selection of location, the mouth, temples, and forehead being favored in this regard. Of course, in well-marked cases, this confusion would not be possible. But some cases of variola are so mild and some cases of varicella are so severe that in the excitement of an alarm of smallpox a doubt is apt to arise. It is expedient to be acquainted with the finer points of difference. The toxic erythemata due to the ingestion of irritating pabula sometimes produce the facies of measles or scarlatina. The absence of the usual concurrent symptoms of the one or the other will mark the distinction. Deliberation and circumspection will prevent a blunder, as the flush of scarlet fever is accompanied by a persistent high temperature, and that of toxic erythema is not. The same distinction holds good as between measles and the toxic condition.

Syphilis is manifested on the face in all its stages and in every diversity of form assumed by that ex-

ceedingly facile adept at disguise. There may be a chancre of the lip, frank and honest, or mimicking a herpes. There may be a chancre of the eyelid mistaken for a stye or an epithelioma. Chancre of the cheek may also be mistaken for epithelioma. Secondary syphilis may produce a corona veneris, grouped lesions about the mouth, and fissures at the angles thereof. The form may be macular, papular, or annular. The eruption may be sparse, or it may be profuse. When sparse the tendency to grouping is noteworthy. The raw ham color so prevalent in luetic lesions is not to be depended on too implicitly, as it may be modified by accidental circumstances. Occasionally, though rarely, the outbreak is vesicular, or pustular. In this guise it has been mistaken for variola or varicella. A careful consideration of all the possibilities is the surest safeguard against error. Most of our failures are attributable to a want of comprehensiveness in our investigations. If we would go far enough afield to postulate syphilis as an eligible factor we should soon get on the trail of confirmatory evidence. The annular lesions of lues are peculiar and distinctive. They occur in the neighborhood of the mouth, as a rule. There may be one or several dime-sized rings discrete, touching, or interlacing, red in the white man, gray in the negro. They are as clear in the center as the clearest type of ringworm. They look as though they were drawn on the skin with the turn of a crayon. The face is favored liberally by the attentions of tertiary lues. Gumma and the tubercular ulcerative lesion are seen in all their variations, and in every conceivable situation. No portion of the surface is exempt. The nose is oftenest singled out for attack. Cheeks, eyelids, forehead, chin, ears may be the point of minor resistance. The punched-out character of the gumma, whether it be round, crescentic, or irregular, is diagnostic. It has a sloughy base and a nasty secretion. The ulcerating tubercular form consists of solid, round infiltrations arranged in circles, crescents, or chaplets of various outlines. They are crusted over superficial ulcerations. The looped, or so-called serpiginous formation, is counterfeited by nothing else unless it be an ancient lupus, and then other elements enter to clarify the situation. When the lesions are small and discrete they closely resemble an acne varioloformis. The latter is not one-sided, and is usually more profuse. The former displays a tendency to get into groups and clusters. Periosteal nodes upon the forehead must not be overlooked. They are as significant as similar growths upon the shins.

The face is the favorite habitat of lupus vulgaris. The nose and adjoining cheeks are especially selected. Any part of the face, however, may be invaded. It is a dark red, raised, sharply outlined infiltrated plaque, studded with little nodules of a reddish yellow color, which resist the pressure of a glass spatula, and remain visible when the surrounding inflammatory area is blanched. These constitute the disease. Aggregations of these tend to ulcerate sluggishly, crusting, sloughing, and leaving tough cicatrices. As already noted, the resemblance to lues is often remarkable. If the nodules can be made out the conclusion is obvious. Usually on the periphery of the main lesion a few isolated nodules are discoverable. It must be admitted that the Wassermann reaction has to be invoked at times to decipher a particularly misleading resemblance. Post factum it is of interest to know that the scar of lupus is tough and that of lues soft and pliable. Lupus erythematosus (which, by the way, is not a lupus at all) generally assumes the contour more or less exact of a bat or butterfly. The imagination has to be called into play very often to sustain this comparison. It is a neoplasm with a sharply circumscribed outline slightly elevated, red surface covered here and there with tightly adherent scales which upon removal reveal the gaping mouths or pouting sebaceous follicles. It may attack any part of the face, and after the nose seems to have a fond attachment for the ear. The scalp (which is never affected in lupus vulgaris) is very often affected in lupus erythematosus. It begins later in life than lupus vulgaris, which in the greatest number of instances begins in childhood. It scars into small atrophic areas, which we find here and there in the midst of the active foci. Lupus vulgaris is the classical cutaneuos expression of tuberculosis, being the direct product of the bacilli. Lupus erythematosus is assumed to be caused, not by the bacilli, but by their toxins, and because of this circumambulatory maneuver is denominated a tuberculide.

Epithelioma has a marked predilection for the face. The lips, nose, eyelids, cheeks, foreheads, ears may any of them be invaded in any part. The under lip presents a very much larger number than the upper. The reason for this difference in susceptibility in tissues of identical structure is not at all clear. The old explanation of the irritation produced by the pipe never has been perfectly satisfying, because the pipe is grasped by both lips, and even if its weight comes on the lower lip some pernicious influence should be felt by the upper. Epithelioma of the lip is an ugly proposition, and should be removed as early in its career as it can be got at. Its contiguity to mucous membrane and to tissues rich in lymphatics accounts for its malignancy. Epitheliomata elsewhere on the face (excepting, it is needless to say, the vicinity of the eye) are much more "benign." They advance much more slowly and metastasize more sluggishly. Still their "benignity" is quite like the harmlessness of a powder magazine which is ready to create a tremendous disturbance if properly stimulated. Epitheliomata are characterized by infiltration, rolled pearly borders, and superficial ulceration. There is usually a history of a persistent scabbing in one small spot for a long time, for years in many cases. No matter what the appearance of the lesion may be, that is a very suspicious circumstance. On the lip it is possible to confound it with a chancre if proper attention is not given to all the features of its appearance and history. This mistake has occurred on the cheek both ways about. While elderly people are more prone to the development of this disease they by no means have a monopoly of it, as it is observed in those who have not reached middle age. Do not discard the diagnosis of epithelioma because the patient is under forty, or even under thirty years old. There are several varieties of this neoplasm, all but one of which present the characteristics cited as diagnostic. The exception is the flat or parchment type, which simply shows a circular lesion with a reddish edge and a yellowish center. It does not ulcerate. It is accompanied by little or no discernible infiltration. Epitheliomata are divided histologically into basal and prickle cell types, and their malignancy is rated accordingly, but it is injudicious to trust to the distinction in the practical management of a given case. There is one and only one royal road to safety, and that is radi-

cal removal as soon as the growth is recognized.

Xeroderma pigmentosum, a rare affection, may be most aptly discussed at this point because of its eventuation in epithelioma, and because of the curious circumstance that it occurs for the most part in children, thereby emphasizing the contention that the age of the patient is no bar to this form of malignancy. It may be described as a premature senilism of the skin, which takes on the degenerative changes (in an aggravated form) which should not appear till late in life. The face has a freckled, weather-beaten appearance, soon followed by scarring and telangiectasis. After a period more or less prolonged, warty or papillomatous tumors appear at the site of the original lesions, and the malignant nature of the disease is manifest. Prior to the tumor stage the appearance is decidedly like that of an *x*-ray burn. It is rapidly fatal after this stage. Acanthosis nigricans is another fatal malady developing verrucous lesions of a blackish hue upon the skin, and in the abdominal viscera active carcinoma. It is also very rare, and it also accentuates the heretofore accepted error that cancer is confined to maturity. Mycosis fungoides is likewise a disease of evil prognosis, some of whose manifestations are on the face. Erythematous or eczematoid eruptions appear and disappear for a period extending over many years in some cases, finally to become permanent and furnish a basis for the development of the fungous tumors which give the disease its name, and on ulcerating bring about the septic cachexia from which the patient invariably dies.

Sarcoma cutis may appear upon the face. It may be of the nodular, the melanotic, or the multiple pigmented variety of Kaposi. The melanotic is the most malignant. It arises from a pre-existing nevus and its activity is pernicious. The last two are seldom seen upon the face, it is true, but their possible appearance there should not be overlooked. The multiple benign sarcoid of Boeck, consisting of little reddish or brownish nodules few in number or actually covering the head, face, neck and shoulders, is a rare cutaneous disease that must be differentiated from its malignant prototype.

The facies of tubercular leprosy is so strikingly repulsive that it is never forgotten. The broadening of the countenance into the remote simulacrum of a lion's head, the fungous flattened, dirty brown tumors, studded over it, the discoloration of the skin between them, the presence of ulcers munching at the nose or ear or eyelid, the dry and lifeless hair, the expression of hopeless misery, constitute a clinical picture unparalleled in dermatology. The macular anesthetic type is also seen upon the face where it does not long remain an unmixed evil, being soon diversified by the appearance of the grosser lesions. Pellagra, arising on uncovered portions of the cutaneous surface, the face is invariably attacked. In the districts where the disease is endemic this is a point of decided importance. Actinomycosis, or "lumpy jaw," is an infiltrated condition of the subcutaneous tissue studded with nodules and riddled with sinuses discharging pus. In the discharge can be found the "ray fungus," the cause of the affliction. Sycosis parasitica, or ringworm, of the beard produces large nodular swellings, the fungus having invaded the hair follicles. It is to be distinguished from sycosis non-parasitica, which is a staphylococcus infection of the same structures. The latter produces individual pustules, each pierced by a hair. It is far more intractable than the other. Tinea circinata or ordinary ringworm of the surface is frequent on the face. It is of trivial importance unless it happens to be confounded with annular lues. Myringomycosis is the portentous title given to a fungous growth in the external auditory canal. It consists of a dirty gray or brownish mould that may line the whole canal and cover the membrana tympani. Scabies never appears on the face of an adult at least outside of Norway. Children in arms may acquire it on the face when the mother's nipples are involved. Pediculosis capitis produces an impetiginous eczema of the nape of the neck, which in filthy people may extend forward to the region of the ears and adjacent cheeks. Impetiginous eczema is nothing but eczema with an added pus infection. Eczema, of course, as the commonest of skin diseases should in the natural order of things be found with great frequency on the face. From earliest infancy to extreme old age this is seen to be the case. The type denominated infantile eczema involving all of the face except the very central portion (containing the nose, lips, and chin) is prevalent in every community where babies are irrationally fed. Erythematous eczema is liable to appear at any age, but shows a particular affinity for the eyes, cheeks and chin of elderly patients. The desire to conceal the evidences of advancing years, sometimes through vanity, sometimes through the need of retaining a hold in the business world, induces many persons, especially women, to resort to hair dyes. These often bring about a dermatitis identical with erythematous eczema. Seborrhoic dermatitis, incorrectly styled seborrhoic eczema, will show itself in greasy patches about the ears forehead or nose. This is always an extension from an affected head. The dryer scales of psoriasis are infrequent much below the hair line. Still their occurrence here must not be ignored, and it is a matter of notoriety that eruptions sparse upon the body may be prominent on the face. The presence of the pearly scale determines the diagnosis. Impetigo contagiosa is repellantly disfiguring and readily mistakable for other dermotoses caused or complicated by pus, such as barbers' itch, poison ivy, and eczema. Its superficial character, its honey-colored crusts and recent occurrence should serve to distinguish it. Dermatitis venenata (Rhus), while indiscriminate in its selection of points of attack, rarely slights the face. Sometimes the disfigurement is portentous and grotesque. Acne facei vulgaris, pustulosa, and indurata is prevalent in all communities. Acne rosacea, somewhat unfairly synonymized as rum blossom, is a very rebellious and humiliating dilatation of the blood vessels of the nose, cheeks and chin, with a marked accentuation of the follicular openings. Rhinophyma is the ultimate possible development of this condition. This has been derisively denominated "tomato nose." The description is not inexact. Granulosis rubra nasi has been felicitously named. It consists of a reddening of the nose, and the development thereon of numerous darker red granulations. It somewhat resembles lupus erythematosus. It occurs in the young and disappears spontaneously. Its differentiation, aside from the purely academic aspect, is important only as regards prognosis. Rhinoscleroma is a very rare neoplastic distortion of the nose, due to the development of hard, flat tumors within and without eventuating in a general broadening of the organ, with contraction of the orifices. It is of parasitic origin. Other granulomata of various types attack the nose and can only be classified by the microscope.

Herpes zoster occasionally appears upon the face.

It is one-sided here as elsewhere, and apart from the pain is of no importance, unless the vesicles threaten the integrity of the cornea. Herpes simplex has a penchant for the face. It is a trivial affection with a curious but well founded connection with latent malarial fever. Urticaria is of general distribution. So is erythema multiforme. The face is frequently involved in both. Erythyma pernio recognized at once under the title of chillblains is quick to attack the nose, ears, and chin. Of assistance in the diagnosis will be the associated involvement of fingers and toes. Prurigo mitis which may be described as an aftermath of chronic papular urticaria in children is very apt to show itself upon the forehead. This has been known to be the deciding point in the differential diagnosis between it and lichen planus, which avoids the face. The generalized redness and scaling of pityriasis rubra, and its clinical counterpart and prognostic antithesis dermatitis exfoliativa, are prominent on the face. Pityrisia rubra pilaris also produces a marked scaliness in this locality. The plugged papules of Darier's disease affect the temples and the slopes of the nose. While pretty rare, it turns up once in a while to our profound bewilderment.

Another curiosity that may confront us at any moment, and find us unprepared, is adenoma sebaceum, which consists of reddish tumors of the sebaceous glands covered with dilated capillaries. It is confounded with acne rosacea until it comes under the observation of the dermatologist. It is a curious and noteworthy circumstance that most of the victims are of feeble mentality. In ichthyosis the face will be harsh and scaly, partaking of the general tendency to hyperkeratosis. Fibromata, neurofibromata, lipomata, angiomata, and lymphangiomata, nævus pilosus, melanotic nævi, any of these neoplasms may mar the comeliness of the human countenance. The golden infiltrate of manthoma affects the eyelids and the inner canthi. It may be the first intimation of lurking diabetes. Cloasma, indicative of derangement of the generative organs, will splotch the cheeks or forehead with its dirty brownish stains. Freckles, so common in the light-complexioned and in the young of no pathological importance, may in the aged become the focus of epitheliomatous degeneration.

The direct antithesis of the hyperpigmentation of the skin is seen in Albinism and leucoderma. In leucoderma the diagnosis is sometimes overlooked because of the apparent or actual intensification of the color at the margin of the disease. The "obtrusive" crescent is the advancing disease the "receptive" crescent the normal skin. Alopecia areata frequently denudes the bearded area in freakish patches. Alopecia luetica is liable to produce a moth-eaten appearance of the same region or even to sweep it clean. Its proneness to assail the eyebrows in connection with the scalp is notorious. Keloid may follow trifling wounds of the face and even acne lesions. It sometimes develops to an enormous degree after piercing of the ears for earrings in negroes. I have seen the diseased tissue many times larger in extent than the organ attacked. Hydrocystoma, which has been more or less correctly called dysidrosis of the face, presents a number of white, deep-seated vesicles with no tendency to rupture, and no inflammatory complications. It occurs in elderly women whose visages have been subjected to the irritation of hot stoves or steaming washtubs. It is persistent. The lesions must be punctured. It is of no importance aside from the disfigurement and the possibility of confounding it with miliaria crystallina or sudamen. Molluscum contagiosum consists of minute globular tumors with a central depression. They are pearly white or slightly tinged with yellow. Curretage removes them effectually. Milia are pinpoint pearly tumors filled with sebaceous matter. They affect the forehead and eyelids. They are to be managed like acne of which they might be considered an abortive type.

The lesions of dermatitis herpetiformis or Duhring's disease are apt to be abundant on the face. Hydroa vacciniforme is practically limited to the face and ears of children. It occurs during spring and summer and is caused by the actinic rays of the sun. The bullæ of pemphigus vulgaris and the denuded or crusting lesions of pemphigus foliaceus, grossly disfigure the countenance. They are to be distinguished from the lesions of bullous impetigo and epidermolysis bullosa. The latter is a curious disease in which trivial trauma causes the speedy appearance of oftentimes enormous bullæ. It is a trophoneurosis. Impetigo dries down into superficial crusts that look as if they were pasted on the skin.

It is a matter of general information that many drugs produce a characteristic outbreak on the skin. Bromides, iodides, copaiba, quinine, antitoxins, antipyrin, are the commonest offenders. But there is hardly a drug that has not its occasional victim. Hypertrichosis facei so ardently desired by the male adolescent is poignantly humiliating to the female. Electrolysis is the only remedy. All depilating applications are not only useless, but stimulating and provocative.

The foregoing imperfect consideration of the clinical significance of the human countenance, in the determining of a great number of pathological conditions, emphasizes the wisdom of giving it the minutest scrutiny as a routine procedure in every instance. This habit once developed, a commanding advantage will be gained over the less observant investigator, who will miss many a hint and circumstance pregnant with important possibilities.

323 West Fourteenth Street.

VINCENT'S ANGINA.

By H. H. Amsden, M.D.,

Concord, N. H.

One of the most valuable contributions which bacteriology has made to medicine is the differential diagnosis of those acute infections which, though symptomatically similar are yet distinct diseases, differing in etiology, hence in treatment. The recognition of the acute infections of the upper respiratory tract is particularly important because so many of them are contagious; hence the necessity for prompt diagnosis and treatment. Recognizing the fact that in many of the acute infections the local symptoms are but the outward manifestations of a systemic disorder, the trend of modern medical treatment is toward a specific therapy based on the bacteriological diagnosis.

History.—The disease which forms the subject of this paper was first described as a distinct affection by Vincent in 1898, though previous to this time Rauchfuss and Babes in 1893 and Plaut in 1894, had described the occurrence of the specific organisms, the fusiform bacillus and spirillum, in ulceromembranous angina, and scurvy. Mayer in 1902 gave the first description of the disease in this country, or, in fact, in the English language.

Etiology.—Infection with the fusiform bacillus and spirillum appears to be the direct cause, though most writers consider that lowered bodily resistance, diseased tonsils, teeth and gums act as predisposing factors. St. Clair Thomson states that it is more frequently met with in debilitated subjects, who live in unsanitary surroundings; that it occurs chiefly in children; and that it is but feebly contagious. Cocks quotes some statistics by Mulholland of 24 cases in the New York Foundling Hospital, in children under five years of age; he considers the disease fairly contagious. Fraley gives an account of an outbreak in an institution for children in Philadelphia, the spread of which was attributed to a common drinking cup.

Pathology.—The lesion in the typical case of the disease is a necrosis of the superficial layers of the mucous membrane. The pseudomembrane is really not an exudate, as appears in diphtheria, but a yellowish or greenish yellow slough resting on an ulcerated base, easily bleeding on touch. The structure first attacked in most cases is the mucous membrane of the tonsil, though the initial lesion may be on any part of the oral or pharyngeal mucosa. In mild cases the ulceration is confined to the tonsil; in the severe cases it spreads to other structures, or lesions are found in other parts of the body. The specific microorganisms have been found in mastoiditis (Yates); in chronic suppurative otitis media and meningitis (Held); in abscesses of the liver and spleen (Schmorl); and in an ethmoidal abscess (Brant).

The few fatal cases on record have generally been due to complications. Goodall reports one due to ulceration of the larynx; Bruce, two fatal cases: one due to toxemia and one to bronchopneumonia, with ulceration of the larynx; Fruehwald, one of meningitis and brain abscess; Rothwell, one with chills, pyrexia, severe pain, cough, and bloody sputum, which contained numerous Vincent organisms; Tunnicliffe, one of general pyemia, with multiple abscesses in various parts of the body, following appendicitis.

Bacteriology.—The specific microorganisms are the fusiform bacillus and spirillum. The diagnosis should always be made from the stained smear. The fusiform bacillus is a long slender rod pointed at the ends with a slight swelling in the middle. In the stained specimen there is an oval unstained vacuole in the center. Besides these long slender forms, shorter rods and long thread-like bodies are also found. Cultures are made with difficulty in serum or ascites-agar under anaerobic conditions. The cultures have a fetid odor. The spirilla resemble the ordinary mouth spirochetæ, are corkscrew shaped and very motile. Cultures may be obtained under similar conditions to those of the bacilli. Smears should be stained with diluted Ziehl's solution, or according to Giemsa. They are Gram-negative. The bacilli alone appear in the diphtheroid or pseudo-membranous variety of the disease, while in the ulcerous form both bacilli and spirilla are found. In fresh cases the fusiform bacilli and spirilla appear in almost pure cultures, while later in the disease the ordinary mouth bacteria are more numerous.

Tunnicliffe and Wright believe that the fusiform bacillus and spirillum are different stages in the development of the same microorganism, and Coplin states that recent observers are of the opinion that the organisms found in this disease, also those allied forms occurring in syphilis and relapsing fever, are not bacteria in the true sense, but are animal parasites, closely related to the trypanosomes.

Symptomatology.—According to Vincent, two clinical forms are recognizable. (1) The ulceromembranous, by far the more common, in which both the bacillus and spirillum are found. The initial symptoms are those of an acute tonsillitis or pharyngitis, malaise, headache, fever, generally slight, and dysphagia. Objectively, there is at first redness of fauces and tonsils, fetid breath, coated tongue, and swelling of submaxillary glands. Later, on tonsils and pillars is seen a soft friable yellowish slough, slightly adherent with marked ulceration of subjacent mucous membrane, easily bleeding on touch. Deep and extensive ulceration of tonsils, pillars and palate may follow, with loss of tissue and subsequent contraction.

(2) The diphtheroid variety is very rare, about 2 per cent. of all cases. It is due to the fusiform bacillus alone. The distinguishing feature of this form is a distinct false membrane, resting on an inflamed slightly ulcerating base; clinically, the two forms are otherwise alike. Rolleston claims that there are not two distinct varieties of the disease, but that the ulcerative is only the later stage of the membranous. Cocks recognizes two types: the tonsillar, or mild type; and the severe form, in which the membrane extends to extra-tonsillar structures, with ulceration, and accompanied by more severe general symptoms. Most cases of the disease are mild affections, yielding readily to local treatment, or self-limited.

Diagnosis.—Vincent's angina must be distinguished from diphtheria, syphilis, and the anginas caused by various pyogenic organisms, especially streptococcus or staphylococcus. From diphtheria the diagnosis is easily established by the stained smear and culture; this is also true of the streptococcus or staphylococcus infections. From syphilis, the Wassermann test may be necessary. In the typical case, the yellowish-green slough, the characteristic fetor, the ulceration, and the low range of pulse and temperature are significant.

Prognosis.—In the uncomplicated tonsillar cases the prognosis is excellent, this form usually clearing up in ten days or two weeks. When unilateral recurrence is apt to take place on the other tonsil. The amount of toxemia seems to depend largely on the extent of the local lesion; in the cases showing extension to larynx or adjacent structures, with ulceration, the prognosis is more unfavorable.

Treatment.—The general treatment is that of any acute infection. As the disease is at least mildly contagious, suitable prophylactic measures should be taken, including an antiseptic mouth wash. For the throat lesions, various local remedies are recommended, as methylene blue, tincture of iodine, Lugol's solution, Monsell's solution, argyrol, solutions of nitrate of silver, in various strengths, and hydrogen peroxide. Orthoform tablets relieve the dysphagia.

The extratonsillar lesions in the severe cases, as deep ulceration of the fauces or larynx, are very intractable to local measures. The lesions in mouth and throat are but the local manifestations of a constitutional process, hence local treatment alone is of little avail in the severe cases, no more so than local treatment in diphtheria.

Acting on the theory that as Vincent's Angina is a spirillum disease, a remedy specific in syphilis should be curative in this affection, Gerber and

Rumpel used salvarsan in Vincent's Angina with markedly successful results. Citron uses a trituration of salvarsan in glycerin locally with permanent cure. Brant reports a case of ethmoidal abscesses treated with a 10 per cent. solution of salvarsan in glycerin with speedy cure. Cocks reports a case treated with salvarsan intravenously.

The writer's personal experience is limited to two cases. The first of these was reported in the MEDICAL RECORD, May 9, 1914.

CASE.—E. C., age 17, family and personal history negative. June 23, 1914, was called to see patient. Subjectively, she complained of sore mouth, headache, backache, rigors, and general malaise. Objectively, pulse, temperature, and respiration were negative. On the roof of the mouth, a serpiginous ulceration covered with a greenish yellow slough, extended from the middle of the hard palate across the soft palate to the right of the uvula; a pronounced fetor was present, there was no adenitis, nor tonsillar involvement. Patient stated that mouth had been sore for several days before my visit. Smear from lesion showed large numbers of fusiform bacilli and spirilla, no other bacterial forms being present. Urine was negative. Blood showed slight increase in lymphocytes and a somewhat marked eosinophilia. An analgesic and Dobell's mouth wash were prescribed. The following day the lesion had increased about a third in area; was much deeper, and more painful, and fetor was very marked. Neosalvarsan 0.6 gram was given intravenously and the general treatment was continued. Reaction was slight, some nausea and rise of temperature to 99.4° being practically all the symptoms. The following day showed much relief subjectively, both local and general, and without further local treatment the lesion healed, in a week, leaving no scar. Examination of smears at frequent intervals showed a gradual diminution in the specific bacteria, these being replaced by the ordinary mouth bacteria.

A CASE OF ACUTE THYROIDITIS.

BY IRVING WILSON VOORHEES, M.S.M.D.,

NEW YORK.

ALTHOUGH acute inflammation of the thyroid gland is not an uncommon entity, its occurrence has not been frequently reported in America. No mention is made of this disease in the authoritative American textbooks on diseases of the nose, throat, and ear. Most of the German and French authors devote some space to its consideration.

The case here reported is that of a man, twenty-six, who was sent to me by his physician for a painful swelling in the neck and difficulty in swallowing. Nothing in the history seemed of especial note save an attack of what seems to have been influenza about two weeks previously. The nose and throat were quite normal, save for some enlargement of the lingual tonsil. No ulceration was present. Externally there was considerable swelling in the region of the thyroid gland. The skin was reddened and the gland itself was quite painful on palpation, especially over the right lobe. There was a slight rise in temperature, with some aching in the back and bones, and general physical depression. A diagnosis of acute thyroiditis was made, the skin was painted with tincture of iodine and the patient advised to apply ice cold compresses. Calomel, 2 grains, was prescribed, and the patient was told to drink large quantities of water and to restrict the diet. After five days the swelling began to diminish, the acute symptoms subsided, and a good recovery followed.

The word thyroiditis is used in contradistinction to strumitis which concerns a chronically involved thyroid. It is said that the condition is either of traumatic, idiopathic, or infectious origin, in which latter circumstance it represents a simple metastasis from some septic focus elsewhere.

Kocher and Tavel report various other diseases in association with thyroiditis and strumitis. These inflammations are inclined to suppurate. Since the gland has no connection with the outside world the infection is in most cases brought to it by way of the lymph and blood streams.

Tavel found varying bacteria present eight times in eleven cases. The organisms were: *Bacillus typhosus, B. coli communis, Streptococcus pyogenes, S. lanceolatus, Staphylococcus pyogenes*, and "*Bacillus strumitidis* a and b." Tavel's findings have been confirmed by others.

Pyemia, pneumonia, influenza, diphtheria, bronchitis, puerperal fever, endometritis, and the second stage of typhus are conditions in which thyroiditis may occur. One case is reported in which thyroiditis was associated with orchitis.

The treatment is that outlined above. If abscess formation seems inevitable, this should, of course, be encouraged by the usual means, and as soon as distinct fluctuation is felt general surgical measures should be instituted. As it is not unlikely that the lingual tonsil is, in some cases, at least, the site of origin of infection, this should be treated by applications of iodine or nitrate of silver, according to the judgment of the laryngologist.

Medicolegal Notes.

Liability of Hospital for Injuries to Employee.—The Texas Courts of Civil Appeals hold that a charitable hospital, which administers to the sick of all nations and creeds, accepting payment if the patients are able to pay, but otherwise rendering the service gratuitously, is liable for damages to an employee for personal injuries sustained through its negligence, and its property is not exempt from execution to enforce the payment of such demand.—Hotel Dreir v. Armendarie, (Tex.), 167 S. W. 181.

Expert Opinion Merely Advisory to Jury.—In an action for personal injuries, the expert evidence was contradictory as to the cause of a benign tumor. It was held that the subject of the cause of benign tumors was one of technical cognizance, of which the court could have no judicial knowledge. The opinion of the plaintiff's experts seemed as reasonable as the contradictory opinion, and it was for the jury to say whether they would be guided by one or neither of such opinions. The expert opinions of doctors were held to be merely advisory to the jury and might be rejected entirely, if believed to be at variance with common sense and experience.—Powmeroulie v. Postal Telegraph & Cable Co. (Mo.) 165 S. W. 1174.

Practising Medicine Illegally—Proof of Residence.—In a prosecution for practicing medicine illegally, the state is required to prove that the accused, with intent to receive compensation therefor, performed services such as are defined in section 1683 of the Civil Code of 1910, without registering in the county of his residence as required by section 1684 of the Civil Code of 1910. The burden is upon the state to prove, as a material fact in the case, the residence of the accused as alleged in the indictment; but the prosecution may rely upon the failure of the accused to attack prima facie or presumptive proof as to residence which is sufficiently strong to compel the production of affirmative proof in order to rebut it.—Hathaway v. State, Georgia Court of Appeals, 81 S. E. 260.

Illegal Medical Advertisements—Insertion by Agent.—In a prosecution for violating Michigan Public Acts of 1907, No. 164, by the publication of an illegal medical advertisement the defendant claimed that the advertisement had been prepared and published by her husband without her authority and consent. It was held proper to charge the jury that it was not necessary, in order to convict the defendant, to find that she personally caused the advertisement to be inserted, it being sufficient if she caused the insertion by her duly authorized agent.—People vs. Kowalski, Michigan Supreme Court, 146 N. W. 177.

POSTINFECTIOUS HYPOPITUITARISM.

FRÖHLICH'S syndrome or the dystrophia adiposogenitalis has been definitely established as a clinical entity resulting from a diminished function of the hypophysis. According to Harvey Cushing, in the typical syndrome of Fröhlich there is an "infantilism both structural and sexual associated with adiposity of juvenile type and an hypophyseal tumor—a combined effect of deficiency of both anterior and posterior lobes." But there are cases that do not correspond with this typical picture. Thus trauma instead of a neoplasm may be the causative factor, while in some cases the loss of hypophyseal function may be secondary to castration or to destructive disease of the genital glands. In one of Cushing's cases there was, instead of a structural infantilism, an actual structural gigantism in the absence of hypophyseal tumor, although a slight degree of hydrocephalus was present.

R. Massalongo and P. Piazza (*Riforma Medica*, September 19 and 26, 1914) describe a postinfectious type of the syndrome adiposogenitalis which they distinguish from the neoplastic type of Fröhlich. Their study is based upon a number of cases of hypopituitarism that came under their observation. They point out that adiposity may result from disturbances in any one or more of the glands of internal secretion, which, in the order of frequency and importance of their causative rôle are the hypophysis, the genital glands, the thyroid, the pineal body (epiphysis), and the suprarenals. The adiposity of endocrine origin has distinct characteristics and runs a typical clinical course. It appears that the posterior lobe or the so-called nervous portion of the pituitary gland pours its secretion into the third ventricle and thereby in some manner prevents the abnormal accumulation of fat in the organism. Hypophyseal adiposity is always accompanied or followed by disturbances or a suppression of the functions of the genital glands. Although the genital impairment is, as a rule, secondary to the hypophyseal lesion, one cannot exclude the possibility of coincident lesions in the genital glands or even in other of the endocrine organs, which in their physiology, both normal and pathological, come into reciprocal relationship with the hypophysis. In acromegaly, which is one of the types of hyperpituitarism, there is observed in contradistinction to the types of hypopituitarism, an excessive activity of the genital glands.

The point upon which the above authors place greatest emphasis is the fact that the syndrome adiposogenitalis may result from any one of diverse morbid processes in the hypophysis, more particularly in its posterior lobe. Such processes consist either of neoplastic infiltration or of degeneration or sclerosis of the hypophysis secondary to an infectious disease. It is this type of pathological change in the hypophysis that may serve to explain those cases of obesity that follow recovery from a disease such as typhoid fever. At any rate, the observations of Massalongo and Piazza open up a new and suggestive field of investigation.

THE TREATMENT OF PRESTERNAL LUXATION OF THE CLAVICLE.

DISLOCATIONS of the sternal end of the clavicle are caused by falls and blows upon the shoulder, the dislocation being anterior or presternal, backward, or upward, according to the direction in which the causative force acts. The anterior, or presternal, is the most frequent variety, and while the recognition of the nature of the lesion and the reduction of the dislocation are easy, holding the head of the bone in its proper position without operation has been the despair of all surgeons who have had these unfortunate cases to handle. The dislocation is reduced by raising the outer end of the clavicle and drawing the shoulder backward, when the head of the bone usually glides into place; although occasionally pressure over the head of the bone may also be necessary. Attempts to maintain reduction have usually been made by the use of the posterior figure-of-eight bandage, the Velpeau bandage, or the spica of the shoulder with a pad over the inner end of the clavicle, the arm being carried in a sling. As a rule, any or all of these methods have failed in the individual case, and the patient has been confronted with the choice of resulting slight deformity, usually with more or less functional disability, or open operation.

Danielsen (*Zentralblat f. chir.*, Oct. 10, 1914) reports a recent experience in a case of this kind occurring in camp before Verdun. The diagnosis and reposition were simple as usual and there was also the usual tendency to recurrence of the dislocation. Noticing that as soon as he retracted the patient's shoulder the sternal end of the clavicle sprang forward, thus reproducing the dislocation, he came to the conclusion that the dressing should be applied in a manner directly opposite to the usual custom, bringing the shoulder upwards and forwards instead of backwards. He therefore raised the arm, holding the upper arm against the cheek while the forearm rested upon the top of the head, and applied bandages to maintain this position. The luxation then remained reduced, healing progressed without any trouble, and the final result was no deformity, with free and painless motion.

Stimson long ago recognized the advantage of the anterior and upward pull on the shoulder, and

suggested the anterior figure-of-eight or Velpeau in some of these cases; but we believe that Danielsen is the first to use the exaggerated position described above. The result was a very happy one in the case which he quotes, and is worth trial by all of us as occasion presents itself; for if generally successful the method will be a great boon not only to the patient but also to the surgeon who has so often been baffled by this dislocation.

PROGRESSIVE TORSION SPASM.

THIS condition was first described by Ziehen under the name of the tonic torsion neurosis. Oppenheim then styled it dystonia deformans, while Flatau preferred the designation progressive torsion spasm. Another term proposed, also by Oppenheim, descriptive of the gait is dysbasia lordotica progressiva. Until its isolation the affection was probably classed under hysteria, and perhaps in some cases athetosis. A patient with this affection shows at least two components. One is the attitude, and the other the peculiar muscular movements. If the patient is at rest on his back with the limbs somewhat drawn up and flexed, the movements are not as marked as when he stands or walks. The muscular activities are in part intrinsic and in part locomotive. They undergo constant tonic contraction and relaxation, the rhythm of which suggests that of clonus. The muscle bellies alternately swell up and dwindle in size. As a result torsion movements especially occur. There is, however, a general restlessness more marked when patient is lying down. As a result of the tonic spasms the spine is flexed and rotated. The thighs participate with the trunk but the muscles of the head and legs proper are involved in a minor degree only. As a result of contractions of the muscles of the trunk and thighs the body becomes somewhat arched, and the spine is often lateroflexed.

A case of this sort was reported by Seelert last summer before the German Society for Psychiatry and Neurology (*Berliner klinische Wochenschrift*, October 5), the patient being a boy of seven years. The chief point of interest was the possible relationship to hysteria. Oppenheim in discussion emphasized the psychic indolence of the patients. Rothmann called attention to some artificial features in the disease picture. Bonhoeffer was satisfied that the affection is not psychogenic. Although at first sight it appeared eminently hysterical, prolonged observation of the evolution of the disease led him to class it among the choreatic processes as an organic disease.

THE PURIN METABOLISM AND THE INTERNAL SECRETIONS.

THE effect of the internal secretions upon the purin metabolism with particular reference to their possible relationship to the origin of gout, was the subject of a fruitful investigation by Fleischmann and Salecker (*Zeitschrift für klinische Medizin*, Vol. 80, Nos. 5 and 6). They found that whereas nucleinic acid fed to dogs is almost wholly eliminated in the urine, the simultaneous administration of pituitary extract causes a lessening and a delay in the excretion of allantoin. If the pituitary extract is fed to an animal whose diet is purin-free, there is at first a slight increase and later a decrease in the elimination of allantoin. In the fasting animal, however, this initial increase is not observed. Suprarenal extract if injected in amounts that are not too small causes a marked rise in the excretion of allantoin without any increase in the total nitrogen elimination. In the case of the injection of phloridzin the results are just the reverse. In thyroidectomized animals nucleinic acid administered in the diet is excreted in smaller amount. Iodothyrin causes a diminution in the elimination of allantoin during the stage of the pronounced protein disintegration. The results of the administration of parathyroid extract have not as yet been uniform. In fasting animals purin bases administered in the diet are excreted in diminished amount, which fact indicates a probable retention. An excessive imbibition of water causes a considerable rise in the excretion of allantoin. The practical significance of the above researches is as yet obscure. Nevertheless, they show an important relation between the various internal secretions and the purin metabolism.

MIGRATING NEEDLES.

THE subject of migrating needles and other pointed objects figures more conspicuously in the secular press than in medical literature. Physicians have long known that the testimony of patients on this possibility is often untrustworthy and that the occurrence of needles, etc., in certain localities, like the female bladder, is due to deliberate introduction from without. This objection, however, cannot be raised in the case of animals, and there is abundant evidence that pointed objects such as needles are swallowed with the fodder, undergo arrest in the gullet and eventually penetrate into the heart, where they may or may not cause death. At a meeting last May of the Aerztlicher Verein of Hamburg (*Deutsche medizinische Wochenschrift*, October 1) Fraenkel related a case in which an aspirator needle, which had broken off while in the thorax of a goat, traversed the left lung and perforated the heart so that death occurred suddenly three weeks after the accident. Some time ago Professor Marchand found at autopsy a needle nicely healed into the myocardium, in which it was rendered visible in skiagrams. No history of an accident could be obtained and the integument was searched in vain for remains of a lesion.

News of the Week.

Examination for Position of Epidemiologist.—The United States Civil Service Commission announces an open competitive examination for epidemiologist, for men only, to fill a vacancy in this position in the Public Health Service for service in the field, at a salary of $4,000 a year. The duties of this position will be to make laboratory and field investigations of the diseases of man in relation to prevalence, causation, and methods of control, and to conduct field studies of public health matters. It is desired to secure persons thoroughly qualified to do laboratory and field research work in epidemiology, and to organize and conduct such work in the field. Graduation with an A.B. or B.S. degree from a college

or university of recognized standing, and graduation with an M.D. degree from a medical school of recognized standing, and at least five years' experience in epidemiological research, including field studies and laboratory technique, and at least five years' public health service under Federal, State, or municipal authorities, are prerequisites for consideration for this position. Experience in epidemiological research and experience in public health service may be concurrent. Applicants must have reached their twenty-fifth but not their fortieth birthday on the date of the examination. Persons who meet the requirements and desire this examination should at once apply for Forms 304 and 2095, stating the title of the examination for which the forms are desired, to the United States Civil Service Commission, Washington, D. C., the Secretary of the United States Civil Service Board, Post Office, Boston, Mass., Philadelphia, Pa., Atlanta, Ga., Cincinnati, Ohio, Chicago, Ill., St. Paul, Minn., Seattle, Wash., San Francisco Cal.; Custom House, New York, N. Y., New Orleans, La., Honolulu, Hawaii; Old Custom House, St. Louis, Mo.; or to the Chairman of the Porto Rican Civil Service Commission, San Juan, P. R. No application will be accepted unless properly executed, excluding the medical certificate, and filed with the Commission at Washington prior to the hour of closing business on December 15, 1914.

Red Cross for Servia.—Two more Red Cross units for work in Servia sail today on the *Finland*. The personnel of the two units consists of Drs. Ethan Flagg Butler and E. P. Magruder, directors; Drs. James F. Donnelly, S. H. Hodge, Clapham P. King, and Morton P. Lane, staff physicians, and twelve nurses. The company will land at the Piræus and proceed at once to Nisch via Salonika. They carry 75 tons of material for dressings and other stores.

Surgeons in the Field.—v. Schjerning, Surgeon-General of the German Army, in a report issued on October 5, stated that there were at that time 9,000 army surgeons of this nationality in active field service. Writing in the *Münchener medizinische Wochenschrift*, Klar makes an appeal for the appointment of orthopedic surgeons as consultants in the field layouts, believing that thereby many limbs and incidentally lives might be saved.

Antitetanus Serum.—In accordance with the now generally accepted view that the value of antitetanus serum lies in its prophylactic rather than its curative efficacy, the French Army medical authorities have issued orders that a preventive injection be given as soon as possible to those receiving shell wounds. Large quantities of the serum, prepared at the Pasteur Institute, have been sent to all the field ambulances for immediate use.

Repudiating British Honors.—Professors Waldeyer, Orth, and A. Martin have added their protests to that of Verworn against the action of Behring, Roentgen, and others in melting down the medals and renouncing the honors conferred upon them by various scientific bodies in Great Britain. They deplore the disturbing of the pure scientific atmosphere by gusts of political rage, and add moreover that it is foolish, for the English will not be in the least annoyed by such puerile actions; they have more important things to think of.

The Death Rate of this city for the week ending November 7 was 11.55 per thousand as compared with 10.60 for the previous week. There was a notable decrease, as compared with last year, in deaths from violence and from scarlatina, measles, typhoid fever, and diarrheal diseases. The death rate for the first forty-five weeks of 1914 was 13.53 per thousand, as against a rate of 13.84 during the corresponding period of 1913.

A Conference of Antituberculosis Workers was held at Syracuse, N. Y., last week, under the auspices of the State Department of Health and of the State Charities Aid Association. Two of the points insisted upon as essential in the crusade against tuberculosis were better ventilation of schools and the establishment of a tuberculosis sanatorium in every county of the State.

Gift from the Mikado to a Hospital.—It was announced recently that the Mikado has donated 50,000 yen ($25,000) toward the foundation of St. Luke's International Hospital in Tokio, which is to be conducted under the auspices of the Episcopal Church Mission, represented by Dr. Rudolph Teusler. The hospital will cost about $500,000 and will be the most elaborate institution of its kind in the Far East, especially advancing medical research work.

Rabies in New York.—During the recent quarter of 1914, 2,136 dog-bitten persons were examined in this city by officers of the Health Department, and 153 Pasteur treatments were given. Sixty-four cases of rabies were discovered in animals and two deaths from human rabies occurred; another death occurred last week, making three deaths for the year thus far. The Health Commissioner announces that despite the protests of some unreasonable owners of dogs, the muzzling ordinance will continue to be strictly enforced.

Physical Examination of School Children by Private Physicians.—In accordance with a suggestion made by the Committee on Hygiene of the Board of Education, two districts in the Borough of Manhattan have been selected in which to carry on an experimental study relative to the possible desire of parents to have their children examined by their own physicians. If these examinations of children entering school for the first time should be made in any considerable numbers by private physicians, it will allow the school medical inspectors of the Department of Health additional time in which to make examinations of children in the upper grades. If this experiment should prove a success, the system will be put into operation throughout the city.

The Forsyth Dental Infirmary for Children.—The new building of this institution, at 140 The Fenway, Boston, will be dedicated with appropriate ceremonies on Tuesday, November 24, at 10 o'clock in the morning.

Accidents to Epileptics.—Dr. Matthew Woods, 1402 Spruce street, Philadelphia, writes that he is preparing an article on "Accidents due to epileptics being unsuitably employed," and would be glad to receive reports of such accidents, together with photographs showing the resultant mutilations.

Translations of Dr. Knopf's Prize Essay on Tuberculosis.—The seventh American edition of Dr. S. A. Knopf's prize essay, "Tuberculosis as a Disease of the Masses and How to Combat It," has been translated into Bohemian by Dr. S. Breitenfeld of New York. The same American edition is now being translated into Spanish by Dr. Jesus E. Monjaras of Mexico City, which makes the

third edition in Spanish, two having appeared in previous years. Dr. A. Lankester, the Government appointee of the Indian Research Fund Association (Special Tuberculosis Enquiry), Cranleigh, Simla, is now translating the essay into a second East India dialect, one Hindu edition having appeared last year. This makes the thirtieth translation of the essay since its original appearance in German some ten years ago.

Dr. William M. Polk has removed his office from 7 East Thirty-sixth Street to 310 Fifth Avenue, New York.

Medical Society Elections.—At the meeting of the New York and New England Associations of Railway Surgeons, held October 21 and 22, in New York City, under the presidency of Dr. C. A. Pease of Burlington, Vt., the following officers were elected: *President*, Dr. W. H. Marcy, Buffalo, N. Y.; *First Vice-President*, Dr. D. H. Lake, Kingston, Pa.; *Second Vice-President*, Dr. H. G. Stetson, Greenfield, Mass.; *Treasurer*, Dr. J. K. Stockwell, Oswego, N. Y.; *Corresponding Secretary*, Dr. Geo. Chaffee, 338 47th St., Brooklyn, N. Y.; *Recording Secretary*, Dr. J. H. Reid, Troy, N. Y. The next meeting, celebrating the quarter-century anniversary of the Association, will be held in New York City on October 21 and 22, 1915.

The Ohio Valley Association, at its sixteenth annual meeting, held at Fort Wayne, Ind., November 4-6, elected the following officers: *President*, Dr. E. O. Smith, Cincinnati; *First Vice-President*, Dr. G. U. Young, Evansville; *Second Vice-President*, Dr. William Shimer, Indianapolis; *Third Vice-President*, Dr. W. H. Harsha, Chicago; *Secretary and Treasurer*, Dr. Benjamin F. Floyd, Evansville.

At the annual meeting of the Republican Valley (Neb.) Medical Association, held at Oxford, on October 29, the officers elected for the coming year are as follows: *President*, Dr. N. T. Johnston, Upland; *Vice-President*, Dr. H. C. Smith, Franklin; *Secretary*, Dr. P. A. Sundbury, Holdrege; *Treasurer*, Dr. W. D. Shields, Holdrege. The next annual meeting will be at Holdrege, Neb.

At a meeting of the medical graduates of the University of Virginia, held in Richmond on November 11, an organization was effected of the Medical Alumni Association of the University of Virginia and the following officers were elected: *President*, Dr. Hugh Young, Baltimore; *Vice-President*, Dr. Richard Whitehead, Charlottesville; *Secretary-Treasurer*, Dr. Thomas V. Williamson, Norfolk.

New York Academy of Medicine.—The anniversary meeting and reception of the Academy took place on Thursday evening of this week. The anniversary discourse, entitled "Some of the Relations of the Profession of Medicine to Municipal Government" was delivered by the Hon. George McAneny, President of the Board of Aldermen of this city.

County Tuberculosis Hospitals.—At the recent election in New York State three counties voted for the establishment of tuberculosis hospitals. These three counties were Chenango, Lewis, and Suffolk. Twenty-nine counties in this State now either have hospitals or have decided to provide them for the tuberculous.

Charitable Bequests.—By the will of the late Dr. Morris Longstreth, formerly of Philadelphia and of Cambridge, Mass., who died recently in Barcelona, Spain, half of his residuary estate is bequeathed to the College of Physicians of Philadelphia, to provide for the salary of the librarian and his assistants, and in addition his medical and scientific books and pamphlets and instruments.

The Litchfield County (Conn.) Hospital has been made a beneficiary under the will of the late Mrs. Mary R. Wilcox of Winsted. The amount will probably be about $30,000.

By the will of the late Henry B. Palethorp of Philadelphia the sum of $5,000 is bequeathed to the Jewish Hospital, the Wills Eye Hospital, the Pennsylvania Hospital, and the Presbyterian Hospital, respectively.

By the will of the late William Lutz of Philadelphia the sum of $5,000 is bequeathed to the German Hospital as a memorial to his wife, Sophia Lutz.

Obituary Notes.—Dr. HARRY H. PEMBERTON of Long Branch, N. J., a graduate of the Jefferson Medical College, Philadelphia, in 1872, and of the Hahnemann Medical College and Hospital, Philadelphia, in 1873, died at his home on November 11, from heart disease, aged 62 years.

Dr. CROWELL C. HALL of Dover, Me., a graduate of the Dartmouth Medical School, Hanover, N. H., in 1876, a member of the Maine Medical Association and the Piscataquis County Medical Society, died at his home, after a long illness, on October 19, aged 61 years.

Dr. JAMES BARTLETT BREWSTER of Plymouth, Mass., a graduate of Tufts College, Boston, in 1862, of the Bellevue Hospital Medical College, New York, in 1866, and of the University of Vienna in 1868, a surgeon in the United States Army during the Civil War, a member of the Massachusetts and Plymouth District Medical Societies, formerly acting assistant surgeon-general of the United States Marine Hospital Service, surgeon-general of the Department of Massachusetts, Grand Army of the Republic, and a State medical examiner of Massachusetts, died at his home on November 7, aged 73 years.

Dr. JOHN C. AMIS of Fort Smith, Ark., a graduate of the Medical Department of the University of Louisville, Ky., in 1883, and a member of the American Medical Association, and the Arkansas and Sebastian County Medical Societies, died at his home, after a long illness, on October 22, aged 55 years.

Dr. JACOB LOPES CARDOZO of Brooklyn, N. Y., a graduate of the University of South Carolina, Medical Department, Columbia, in 1878, a member of the Kings County Homeopathic Medical Society, chief of staff of the Gates Avenue Homeopathic Dispensary, and physician to the Eastern District Dispensary and Hospital, died at his home on November 3, aged 82 years.

Dr. JOSEPH C. DOANE, formerly superintendent of the Miners' Hospital at Shamokin, Pa., has been appointed Chief Resident Physician to the Philadelphia General Hospital, vice Dr. Henry Sykes deceased.

Dr. HENRY NORTHAM BRYAN died on November 2 at Philadelphia at the age of 61 years. He was graduated from Jefferson Medical College in the class of 1884 and from the Medico-Chirurgical College in the class of 1895. He was for many years chief clinical assistant in the surgical dispensary of the Medico-Chirurgical Hospital. He was a member of the Philadelphia County Medical Society and of the Medical Society of the State of Pennsylvania, a Fellow of the American Medical Association, a Fel-

low of the College of Physicians of Philadelphia, and a member of the Philadelphia Medical Club.

Dr. PHILLIP G. CREVELING of Broadway, N. J., a graduate of the Department of Medicine, University of Pennsylvania, in 1857, died at the home of his daughter, recently, aged 80 years.

Dr. EDWARD HODGES of Brooklyn, N. Y., a graduate of the Long Island College Hospital, Brooklyn, in 1895, attending gastroenterologist to the Swedish, Bushwick, and Samaritan Hospitals, Brooklyn, and the Polhemus Memorial Clinic, assistant surgeon in the Forty-Seventh Regiment during the Spanish-American War, and a member of the American Medical Association, the New York State and Kings County Medical Societies, the Associated Physicians of Long Island, the Long Island Medical Society, of which he was a former president, and the Alumni of St. John's Hospital, died at his home, from pneumonia, on October 30, aged 44 years.

Dr. OSMON B. WAY of Claremont, N. H., a graduate of the Dartmouth Medical School, Hanover, N. H., in 1866, a member of the New Hampshire and Sullivan County Medical Societies, consulting physician to the Claremont General Hospital, twice a member of the New Hampshire State Legislature, and for some years a trustee of Boston University, died at a sanatorium in Brattleboro, Vt., after a long illness, on October 26, aged 74 years.

Dr. EDWARD HARVEY TAFT of Milford, N. H., a graduate of the Dartmouth Medical School, Hanover, N. H., in 1897, a member of the New Hampshire and Hillsboro County Medical Societies, and president of the Milford Progressive Club, died suddenly at his home on November 3, aged 45 years.

Dr. SAMUEL S. APPLE died at Easton, Pa., on November 11 at the age of 75 years. He was graduated from Jefferson Medical College in the class of 1869. He served as cavalryman during the Civil War and he was for many years surgeon to Lafayette Post G. A. R.

Dr. ANDREW S. LOW died at Philadelphia on November 9 at the age of 77 years.

Dr. JOSEPH SCRIBNER GIBB died at Philadelphia on November 7 at the age of 55 years as the result of an attack of apoplexy. He was graduated from the medical department of the University of Pennsylvania in the class of 1880 and he then served as resident physician in the Philadelphia Hospital. From 1882 to 1892 he was outdoor physician to the Department of Charities and Correction and surgeon to the Police Department, and from 1881 to 1884 he was in charge of the Nose and Throat Department of the Northern Dispensary. Since 1893 until recently he was surgeon to the Ear, Nose and Throat Department of the Episcopal Hospital and from 1897 to 1913 Professor of Diseases of the Throat and Nose in the Philadelphia Polyclinic and College for Graduates in Medicine and since the last date emeritus professor. He was a Fellow of the College of Physicians of Philadelphia, a member of the American Laryngological Association, the American Laryngological, Rhinological, and Otological Society, the Philadelphia County Medical Society, the Medical Society of the State of Pennsylvania, and the American Medical Association.

Dr. JOHN MORGAN HOWE of New York, a graduate of the New York Homeopathic Medical College and Hospital in 1879, and a member of the American Institute of Homeopathy and the New York State Homeopathic Medical Society, died at his home on November 13, aged 70 years.

OUR LONDON LETTER.

(From Our Regular Correspondent.)

WAR ITEMS—"DUM-DUM" BULLETS—DARK STREETS OF LONDON—EARLY CLOSING OF LICENSED HOUSES—DANGER OF INTEMPERANCE—TETANUS—SOLDIER'S HEART, ETC.

LONDON, October 29, 1914.

"*Bellum, horridum bellum.*" The war absorbs so much of our thought in its many aspects that even when doctors meet to discuss professional questions the great topic is sure to intrude and not seldom displaces all others. Let me, then, make a few notes on the prevailing subject or medical items connected with it. Sir A. Sloggett has gone to France as the chief commissioner there of our Red Cross and St. John Ambulance associations, besides which he will be director-general of the expeditionary force. He will, it is expected, be in a position to coordinate the work of these two voluntary bodies with that of the R. A. M. C., thus preventing overlapping and securing more satisfactory results than could be obtained from separate organizations.

Sir J. Rose Bradford, Sir W. Herringham, and Sir Almroth Wright have been appointed consulting physicians with the rank and provision of colonel to the expeditionary force and have gone, accompanied by three bacteriologists. A sanitary committee, to advise the army council on hygienic questions connected with the troops engaged, has also been appointed from officers of the Army Medical Corps, reinforced by some of the public health service and the engineers. This committee should prove very efficient and of no slight use to the A. M. C. and still more, perhaps, to the medical officers connected with the recruiting service now so active as well as those with the territorials. Mr. Burghard has started as surgeon and Dr. T. R. Elliott and Dr. Alexander Fleming as assistant physicians.

Sir Alfred Keogh, K. C. B., who has for some time been abroad in connection with the Red Cross service, has been recalled to act as medical director-general during the vacancy. He formerly held this appointment for a period of five years.

An outcry has been raised, as in former conflicts, against the alleged employment of the so-called "Dum-Dum" bullets. There seems no proof of any such violation of the treaty or arrangement between the powers, but the public is sensitive on the subject and unsupported assertions get circulated. Consequently civilian friends press their doctors with all sorts of questions about them and the character of the injuries they inflict. Not having handled them myself I recommend inquirers to ask those who have been army surgeons, but this does not satisfy all. Some seem to think every doctor must know and ask further what then are the "humane bullets" we hear about and what is the difference between them? So I have to tell them, again warning them it is merely what I have heard, that these are more sharp pointed, but the question of their being humane is doubtful—whether in regard to the fatality or the pain caused by the wounds they make. Professor Fessler's report was that they are more apt to turn on their axis as they pass through the tissues and would thus cause more damage in the cavities of the head, chest, or abdomen than the original Dum-Dum would do. This and its imitations tend rather to break into pieces in the tissues and are pretty certain to do so when

they strike bone. Not only so, but bits of the core or of its envelope are carried into the wound as may be other foreign bodies, as of the clothing. Splinters of fractured bone may also be found in the wound. I have said there is no proof that these missles have been used in this war, although rumor has been as busy as usual on the outbreak of hostilities, but their use is against the recognized customs of war between civilized nations and could only be admitted on unimpeachable evidence. A surgeon-general of extensive experience repudiates the charge which is usually made only by those who have not had the opportunity of war service.

The streets of London have of late been comparatively dull in the evening. The order to turn the gas low has removed the excessive glare which was proverbial and people who walk about talk of the semidarkness. Some, interested above all in their own convenience, grumble but have nothing to answer when asked what they do when they go into the country—except the one so obsessed with his grumble as to say "they have the moon there," and wonder why he was ridiculed.

In connection with this the earlier closure of public houses has been carried out. The licensing authority on the 15th inst., with the support of the Government, ventured to order all licensed houses in London to close at 10 P.M. The temperance party are rejoicing over a victory they have long fought for, but the authorities though sympathizing had not the courage to decree. This is a war item, for the danger of drunkenness among troops is once more exemplified by the German atrocities, many of which are no doubt due to the maddening effect of the looted liquors consumed during their pillaging.

The scheme for providing free medical attendance with drugs and appliances to the dependants of soldiers and sailors serving with the columns may be considered a success. The Government committee on the Prevention and Relief of Distress in conjunction with the National Relief Fund Committee, together with the representatives of the British Medical and Pharmaceutical Associations have cooperated to carry out the intentions of the promoters in a comprehensive manner; doctors and chemists in all parts of the country have agreed to render their services in accordance with the scheme which seems to be simple and practical.

You will not be unprepared for the announcement that a number of cases of tetanus have occurred among the wounded. Some have appeared after arriving in the Paris hospitals, which is not surprising considering the long incubation period that only the slightest wound may afford access to the microbe and that the earth would be so disturbed at the front. It has been asserted that the soil in the Aisne valley contains an excessive number of tetanus bacilli compared with other parts. The statements as to this seem to me speculations rather than evidence.

Emphysematous traumatic gangrene is considered to be somewhat allied to tetanus, and cases of it are also reported among the troops. It is, of course, possible that this "gas gangrene," as it is commonly called, may predispose to tetanus and as it occurs mainly under the same conditions may be even probable. But so little is known of it that this and other points that have been raised are only subjects of conjecture.

It is reported that antitetanic serum is being freely used by the French surgeons on the line and in the military hospitals.

At the Institute of Hygiene on Tuesday Dr. Strickland Goodall gave an address on "Soldier's Heart," in the course of which he referred to the remarkable endurance of Sikh troops, who are perhaps the best trained regiments in the world, but are not altogether exempt from this trouble. Among ordinary troops 2 or 3 per cent. will fall out from heart trouble on a march of 100 miles. Two batallions of Sikhs lately marched 52 miles at an average pace of 4 miles an hour. Most of the marching was at night when the actual rate was 5 or 6 miles. No European regiment could do that, yet only four cases of heart failure occurred in those 2,000 men during the whole march. Dr. Goodall considers the soldier's heart as a variety of the athlete's heart and said at least one-third of recruits rejected on medical grounds were refused on account of the heart. Nevertheless, breakdowns among soldiers in the first three months of training were generally due to the same cause. But he added that heavy arms carried and the effects of belts and bandoliers combined to increase the liability, while in forced marches some men always fell out from cardiac failure.

Lord Kitchener has appealed to the public not to treat soldiers with drink (a common practice), but rather to assist them to resist temptation to which they are so much exposed. Where soldiers are stationed Lord Kitchener suggests committees might be formed to advocate public opinion on the importance of our defenders being in the highest state of efficiency and this, of course, implies strict temperance.

OUR LETTER FROM THE PHILIPPINES.

(From Our Special Correspondent.)

CHOLERA CARRIERS—FUTILITY OF THE FIVE-DAY QUARANTINE—LOW CASE MORTALITY—MANAGEMENT OF THE CHOLERA EPIDEMIC—AUTOMOBILE DISINFECTING CAR—MANILA MEDICAL SOCIETY—CLEAN-UP WEEK FOR THE PHILIPPINES—PERSONAL.

MANILA, October 15, 1914

In the recent occurrence of cholera in Bilibid Prison, out of a total daily average of some 2400 prisoners, 84 have been found by the Bureau of Science to be positive cholera carriers, or 3 per cent. Of these carriers, who were held in complete isolation, four developed cholera after being found to be carriers. One developed the disease four days after being found positive, one 16 days, one 17 days, and one 18 days. In the quarantined cell houses cases have occurred at from two and three up to twelve and thirteen-day intervals. At the San Lazaro detention camp one cholera carrier developed an attack of the disease twenty-one days after being found positive. All this has an intensely practical bearing as it illustrates the futility of the usual five-day quarantine as an effective safeguard against the spread of cholera in a very respectable percentage of infections. It also explains very many outbreaks most difficult to understand under the old hypothesis of a five-day incubation period of cholera. Also it very clearly shows the absolute necessity in fighting cholera in looking for the infection outside of the actual cholera cases. In the present outbreak in Manila, the search for cholera carriers is being prosecuted at the rate of about two thousand examinations a day, and about twice as many carriers as actual cases have been found and isolated. These carriers require about two weeks on an av-

erage to clear up, and it is evident that if allowed to remain at large they would be a far greater danger to the public safety than actual cases. Indeed, it is believed by Major Munson, acting director of health, that a most serious epidemic in Manila has been averted only by the systematic and persistent searching out and isolation of the cholera carriers. No effort is being made to examine the population as a whole for cholera; but all contacts with cases, all residents of a vicinity where a number of cases have occurred, and all persons handling food are examined.

Usually a sample of feces is secured and inoculated on culture tubes furnished by the Bureau of Science, but in a good many instances where it is undesirable to wait for a fecal specimen, swabs are inserted in the rectum and inoculation of the media made in this way. It seems, however, as if these rectal smears are not as reliable as cultures made from fresh bowel movements. Rectal smears may give negative results where feces show positives. A number of cases of intermittent carriers have also been discovered, the moral of which of course is that while positive findings are conclusive of danger, a negative finding is by no means indicative of freedom from infection. Efforts for intestinal antisepsis have as yet proved unsatisfactory. Aromatic sulphuric acid, five drops t.i.d., has proved about as satisfactory as anything in clearing up carrier cases. A fairly large experience with salol does not indicate that the latter has any particular value. In fact, several cases of cholera have occurred in carriers who were receiving ten grain doses of salol twice daily, and the elimination of infection from ordinary carriers does not seem to be hastened in any degree by this treatment.

The extraordinarily low case mortality of cholera in Manila still continues. The doctors at San Lazaro state that only about 25 per cent. of the cases that reach them result fatally, while previous epidemics have run as high as 70 and 80 per cent. There were thirty-nine consecutive cases from Bilibid with only four deaths, though all were confirmed bacteriologically. The clinical symptoms are those of cholera, but of an extraordinarily mild type —purging, cramps, collapse, suppression of urine, etc., but all in much less than the usual degree of intensity. Some slight cases are clinically no more than colic with bowel looseness, and of course there is every degree of severity from the immune carrier up to the case of cholera sicca that dies in perhaps a few minutes. This matter of immunity is most interesting. Why is it that a case will harbor germs for three weeks in apparent safety, and then without demonstrable cause suddenly develop an attack? Is there an anaphylaxis, or does the attenuated cholera vibrio take on a more virulent character? None of the carriers who have come down with cholera while under detention have been undergoing anything in the way of deprivation or hardship which could lower vital resistance generally. The hypothesis that the germ itself acquires qualities of virulence beyond the power of the system to resist, in a certain percentage of carriers, is rather favored by the existence outside of Manila, in certain provinces, of a type of cholera which entirely conforms to that of previous outbreaks, having its case mortality of about 80 per cent. Moreover, examinations of many hundreds of tubes inoculated from contacts or neighbors have as yet failed to show cholera infection in a single case from the provinces, while in Manila 3 per cent. of all examinations are positive. The conclusion seems almost warranted that in Manila there is an attenuated strain of high resistance but such low virulence that most of the people who harbor it never show signs of sickness, while in the country the infection is so virulent that those who get it almost invariably become violently sick and the vast majority of such promptly die.

The rise in city cholera which resulted from the big flood has now about subsided, but the heavy rains in the provinces have done much to spread the infection there. So far it seems completely under control, though new foci of infection are constantly starting up. A smart epidemic in Bulacan has been completely stopped, and despite the large number of towns which have presented one or several cases, no serious outbreak has occurred except in Union Province, where sanitary effort is now being concentrated. The disease got a start there from the presidentes either neglecting or refusing to report the existence of cholera in their communities until it had become well scattered. However, after a week of systematic effort the cases have been reduced to a third of what they were in Union Province. No great outbreak is apprehended, but the cases are sufficiently numerous and scattered to keep the health officials constantly alert and busy.

To do away with this danger the health authorities have requested that buckets of disinfectant solution be kept in every public midden shed, and that signs be posted directing people to wash their hands therein before leaving. Also an effort is being made through the native papers, physicians, etc., to have the people take up the use of eating utensils, with such effect that a native member of the City Council of Manila introduced a resolution making it a misdemeanor for anyone to use the fingers in eating. The matter was finally compromised by an order being issued that restaurants in public markets must furnish spoons or forks with food to be eaten on the premises. In Manila more and more proof is accumulating that practically all cases are contact infections, largely spread by carriers. The health officials are conducting a campaign for personal cleanliness and for the use of spoons and forks instead of the fingers in eating, which latter are habitually employed by the lower classes. As these people use no toilet paper, but may wash the anus after defecating with a few spoonfuls of water held in the hands, and do not wash such hands before eating rice from a common dish with them, it is not difficult to understand how cholera infection is spread from one to another among families and friends. The Chinese, who eat with chopsticks, have noticeably escaped the cholera infection, though their practice of eating only cooked food, and drinking boiled water in tea, probably assists in their relative immunity. The old Biblical injunction to wash the hands before eating and after defecation, and in default of water to go through the process with clean sand, is certainly a valuable sanitary requirement. This practice still obtains among the Mohammedans, and the Moors of the Philippines carry it out, but in such a defective way and with such an obvious idea that it is merely a ritualistic form that the procedure is practically robbed of its sanitary effectiveness. In the provinces, what cholera there is seems practically attributable to the use of contaminated surface water. Where artesian wells exist cholera cases are either nonexistent or but few in number. A large number of shallow wells are being disinfected, which the late

rise in cost of potassium permanganate, amounting to nearly a thousand per cent., makes a rather costly matter.

Health officials report the new automobile disinfecting car to be a great success. One disinfecting gang with this car is doing with ease all the work that two gangs with carretellas were required for. The doctor, ambulance, and disinfecting gang often reach a house within five minutes after their services have been telephoned for.

A meeting of the Manila Medical Society was held in the College of Medicine and Surgery on October 5. A paper was read by Dr. Ferdinand Schmitter, army medical corps, on "Malassezia Furfur as the Cause of Tinea Versicolor." Dr. Schmitter has been doing a large amount of investigation into the part played by yeasts in the development of disease in the tropics. Dr. Saleeby presented a case which was apparently a combination of beriberi and scurvy in the same person.

The newly organized Social Welfare Board has called for a "clean up week" for the entire Philippines, to be held the first calendar week in December. The Bureau of Health, the Bureau of Schools, the Constabulary, and other branches of the government are combining to advertise the project, outline local plans for improvement and direct local efforts to best advantage. It affords an excellent opportunity to draw public interest to sanitary matters, and the health department proposes to take every advantage thereof.

Dr. Eleanora J. Pond, one of the attending women physicians at the Mary Johnston Hospital, has just been made secretary of the Board of Medical Examiners, relieving Dr. C. E. Norris of the Bureau of Health, who has applied for leave of absence to return to the United States.

6. A Comparative Study of Three Methods for the Diagnosis of Tuberculosis by Sputum Examination. R. Ernstbek.

1. **Anaphylactic Skin Reactions in Hay-Fever Subjects.**—J. L. Goodale describes the reactions occasioned in hay-fever patients by the application of various pollen extracts to an abrasion of the skin. The use of the skin test in hay-fever subjects to determine the special toxic pollens has the advantage over a test carried out on the eye or nose of permitting a number of determinations to be carried on simultaneously as well as being much more acceptable to the patients. The plants which were selected for determination were in addition to the well-known excitants of hay-fever various grasses and ragweed, also a number of the more common plants flowering in spring and summer, chiefly the anemophilous ones in which fertilization is accomplished by airborne pollen. The extracts were prepared by soaking the pure pollen for 24 hours in a 15 per cent. dilution of alcohol and filtering. The test is applied by placing a drop of pollen extract upon the previously sterilized skin of the arm and making with a pointed knife or paracentesis needle a superficial scratch about one-eighth of an inch in length, sufficiently deep to cause blood to appear. The solution of pollen is then gently rubbed into the scratch with the knife blade. If the reaction is positive it occurs in the course of five to ten minutes, first as an elevation of the skin bordering the scratch, proceeding more or less rapidly in all directions for a distance ranging from one-eighth to one inch. In pronounced reactions the elevated area is surrounded by a hyperemic border and more or less itching is noted. The duration of the swelling is from one to three hours, the whole finally disappearing completely. In moderate reactions the margin of the skin is even and regular; in more intense reactions there occur alterations more or less sinuous with irregular prolongations. The color of the elevated surface ranges from a slight to an intense pallor most marked at the site of the scratch.

3. **Asthma in Children and "Egg Poisoning."**—F. B. Talbot believes that asthma is a manifestation of anaphylaxis and conceives that the urticaria seen on the skin may also involve the mucous membrane of the bronchi and thus give rise to the symptoms of asthma. In some children asthma is due to egg poisoning. Inoculating a scarified area of the skin with egg albumin will indicate whether the latter is the specific cause of the asthma or not. Many if not all patients suffering from egg asthma may be immunized to egg albumin by feeding the patients with gradually increasing doses of egg albumin in capsules. When the egg idiosyncrasy is cured the ashma stops unless an idiosyncrasy to some other protein complicates the situation. Horse asthma is an anaphylactic phenomenon due to the protein of horse serum and may be recognized by scarifying the skin and applying horse serum. A reaction similar to that produced by egg albumin results. It is as yet impossible to state whether or not other proteins have an etiological relation to asthma.

5. **Transfusion in Hemorrhagia Neonatorum.**—R. M. Green points out that transfusion is a procedure of definitely established specific curative value in the treatment of hemorrhagic disease of the newborn. By its use the mortality of this disease has been reduced from 50 to 10 per cent. A probable further reduction of mortality may be expected in the future from the more prompt and universal application of this method of treatment. Improvements and simplifications in the technique of transfusion have now made its performance possible by surgeons of average training, experience, and skill. Of the methods thus far devised that of Kimpton is regarded by the author as superior in certainty, speed, and ease of accomplishment. Even with transfusion the prognosis in the rare cases of hematuria neonatorum is apparently much worse than in any other form of bleeding in the newborn. The greatest present need of further investigation in hemorrhagic disease of the newborn is into the knowledge of its probably syphilitic etiology.

1. **General Anesthesia in Surgery of the Genitourinary Tract.**—J. T. Gwathmey states that most patients to be anesthetized either locally or generally should have the benefit of physiological doses of morphine

before anesthesia, and also of an alkali and carbohydrate treatment both before and after operation. In very weak and feeble patients and for those in the extremes of life, or where exhaustion with acidosis is present; also in instances in which the patient is in a state of coma or has acute or subacute nephritis or any respiratory affection, the morphine should be omitted and bromides or paraldehyde and olive oil per rectum should be substituted. The essence of orange-chloroform-ether sequence, or the nitrous oxide-oxygen-ether sequence should be used instead of ether by the drop method or the "gas ether" sequence. Chloroform throughout is the anesthetic of choice for chronic alcoholics in fair condition. Oil-ether colonic anesthesia is indicated for the very obese. For office work and short operations it is both safe and satisfactory to use only nitrous oxide and oxygen without any preliminary medication or the addition of ether. For major operations in genitourinary surgery patients can be narcotized with nitrous oxide and oxygen alone if proper preliminary medication is given, and this combination should be more frequently employed.

5. **Implantation of the Generative Glands and Its Therapeutic Possibilities.**—G. F. Lydston finds that successful total or partial implantation of human sex glands in both male and female is practicable. Glands taken from the living subject are most desirable, though rarely obtainable. Glands taken from the healthy dead body at any time prior to the beginning of decomposition are of therapeutic value equal to that of those taken in vivo if implantation succeeds. In human beings the gland of one sex is transplantable upon the other and it is possible that the hormone of the one is useful to the other. The author's experiments apparently show that the tissues of the female are more hospitable to the implanted male sex glands than are the tissues of the male. The benefiits of implantation probably accrue irrespective of the site of the implantation, but the vicinity of the peritoneum (extraabdominal) in the female and of the tunica vaginalis in the male are the sites of election. The development of senility possibly can be retarded and longevity increased by internal sex secretion derived from implantation. The climacteric may be postponed by it or the disagreeable features of the climacteric relieved. Defective and aberrant psychical or physical sex development and differentiation—inversions and perversions—are definite indications for sex gland implantation. Certain cases of cryptorchidism and imperfect testicular development are an especially promising field for it. Chronic diseases of the skin due to or modified by nutritional disturbances—notably, certain types of chronic eczema, psoriasis, and ichthyosis—in a certain proportion of cases apparently are likely to be benefited and possibly cured by sex gland implantation. That arteriosclerosis will in its early stages be benefited by sex gland implantation is probable. Inferentially if taken early senile dementia possibly may show beneficial results. All conditions incidental to sex gland mutilations in either sex afford a positive indication for sex gland implantation, the probability of benefit being inversely as the length of time that has elapsed since the mutilation and dependent on the age at which it occurred. The most important point of all is that in properly selected cases successful implantation ought inevitably to increase physiological efficiency with all the benefits accruing therefrom. With increased physiological efficiency come individual and social efficiency.

6. **Pilocarpine in High Blood Pressure.**—W. D. Robinson states that for the past few years he has used pilocarpine with good results in practically all cases of hypertension of blood vessels without marked cardiac hypertrophy and with gratifying results in nearly all instances. Its use gave evidence of modifying the cause of hypertension. The dose was a fraction of that usually taught as the normal dose. The records of heart action and blood pressure change were always closely watched, as was also the effect on sensible sweat. The starting dose for adults in fair condition was one-thirtieth of a grain in a glassful of water after meals. This occasionally had to be still further reduced and seldom increased in order to secure a gradual decrease in blood pressure amounting to about thirty to forty mm. Hg after four to six weeks of administration. The therapeutic dangers usually accredited to this drug have not been met with in the modified dose in which it has been used, a dose that is not mentioned in works on therapeutics and materia medica. The general feeling that the drug is a dangerous one is attributed to the practice of administering the maximum dose of one-tenth to one-fourth grain.

7. **Relief of Gas Pains After Appendicectomy.**—T. A. Kenefick points out that the history of most cases of appendicitis includes the symptoms of intestinal fermentation with the usual depression and discomfort. These are the result of fermentative action due to food and the presence of various forms of bacteria and their ultimate gaseous products. The combination of twenty grains of acetyl-salicylic acid with one grain of calomel and five grains of sodium bicarbonate mixed and given in two or four ounces of water the afternoon preceding operation, followed by the usual enema the next morning, has produced good results in relieving the gas pains. The drug is harmless and can be given alone if calomel is objectionable, but the cathartic effect is desirable. The dose of each varies according to the age of the patient. If by percussion the abdomen later shows evidence of a beginning distention ten grains can be given the next day as the result of which relaxation soon occurs and the threatened tension and distress are aborted and held in abeyance until the tract can be safely unloaded.

8. **Focal Infection of Nose, Throat, Mouth, and Ear.**—J. C. Beck states that the streptococcus, staphylococcus, and pneumococcus are the most frequent causes of chronic focal infection, but that their toxins are practically the same, being proteins. The patients may show no symptoms excepting that they may complain of not feeling well and may be unable to do good work. In all such cases the focus of infection should be sought

for and the mouth, nose, throat, and ear should be carefully examined, as there may be chronic infection from a focus that hardly reveals itself. Aside from the eradication of the focus the treatment should aim at increasing the general resistance of the patient. The tonsils and adenoids are most frequently involved as foci of local infection and conditions apparently far removed from them may be relieved by the treatment of the foci and the increase of the general resistance of the patient. Not alone is the nose or ear in a suppurative condition often cured by the removal of tonsils or adenoids, but a suppuration quite distant from the tonsils, as in the bladder or uterus, is sometimes markedly relieved or cured.

12. **Cyst of Left Cerebral Hemisphere.**—C. M. Remsen reports a case of this condition in a man aged fifty-nine. The history suggested a hemorrhagic destruction of brain tissue with aphasic symptoms, followed later by an increase in the symptoms which indicated a progressive, growing lesion. Motor and sensory disturbances rapidly became evident. The drainage of the cyst by a subdural route was made necessary in view of the desire to avoid external drainage, by the jelly-like consistency of the brain tissue which absolutely precluded the possibility of manipulative procedures in this region. There was an accumulation of fluid under the dura at about the sixth week, as demonstrated through the trephine-holes and the associated psychic and sensory motor disturbances. There was an absorption of the subdural fluid with a consequent improvement in the symptoms. There was a complete disappearance of the Jacksonian epileptic attacks and of the dragging of the foot, a striking improvement in the motility of the right hand, a betterment, often striking in character, of the sensory, sterognostic, apraxic, ataxic and position-sense disturbances.

13. **Diagnosis of Epilepsy.**—L. P. Clark has called attention to the expressionless quality of the epileptic voice. It usually renders the frank epileptic incapable of singing beautifully or speaking well. When the voice defect is once pointed out it is obvious to any one. Instead of the continual rise and fall in melody the vowels and phrases run along in even tones. The speech of the epileptic may thus be designated as "plateau speech," that is, the melody proceeds by even steps. Several years ago the author reported a new and rather rare form of rapidly recurring petit mal epilepsy and gave the details of the bizatte attacks in persons affected by it. The attacks in this peculiar form of epilepsy are in most instances a simple awakening from sleep and occur a hundred or more times in a single night. The point of special interest is that the peculiar attacks are immediately increased by the ordinary doses of bromide (from 60 to 120 grains daily); but as the dose is increased from 120 to 180 or even 230 grains daily, all attacks cease. Bushy and the author analyzed thoroughly the gastrointestinal tract of a small but selected group of epileptics and found an abnormal position of the various parts of the gastrointestinal tract present in every case examined. A point of considerable practical moment following *x*-ray examinations has been the more or less definite indication as to just to what parts of the abdomen one should apply kneading and massage movements over the large intestine. This therapeutic procedure is of the greatest value, particularly when there has been a tendency to stasis in the ascending colon. *X*-ray examination in epileptics has shown rather remarkable changes in the posterior clinoid processes which often hook over so as nearly to close the sella cavity.

14. **Tubercle Bacilli Cultivated from the Blood.**—H. K. Faber reports the production of a successful culture of tubercle bacilli from the blood post-mortem of a tuberculous child. The blood was taken directly from the heart cavity and the culture which was not originally attempted for a demonstration of tubercle bacilli was made on an agar slant and its success was unexpected. Inoculation experiments were made on guinea-pigs and verified the culture. The conditions were such that aerobiosis was complete.

16. **Parenchymatous Nephritis from Mouth Infection.**—G. F. and G. R. Dick describe two cases of typical non-suppurative nephritis with positive bacteriological findings. In the first case which was apparently acute nephritis the portal of entry for the organisms was probably a pyorrhea, the bacterial flora of the urine corresponding closely with that of the pus from the gums. In the second and more chronic case the atrium of infection was not so clear though the organisms found in the urine are commonly associated with diseased tonsils. Proof is wanting that the organisms found in the urine caused the associated nephritis. The author, however, found that in forty-two normal women the urine was sterile in thirty-eight cases and that only a few organisms such as *B. coli* were present in the remaining four cases. The continued excretion by the kidney of organisms in quantities such as were found in these cases suggests that such organisms are the probable cause in at least some cases of perenchymatous nephritis.

17. **Tumor of the Crus Cerebri.**—J. H. W. Rhein reports a case of a tuberculous tumor in the left crus cerebri invading the upper part of the pons, affecting the nuclei of the third nerve, and extending upward into the basal ganglia. The paralysis of associated movements upward, downward, and laterally, indicated a lesion of the pons in the neighborhood of the oculomotor nuclei and a lesion of the posterior longitudinal bundle. The characteristic symptom-complex of tumor of the crus is said to consist of a hemiplegia on the side opposite to the lesion with oculomotor palsy on the same side as the lesion, but in fourteen of the eighteen cases collected from literature, including the author's case, the oculomotor palsy was on both sides in nine instances and one one side in five instances. In rare instances the hemiplegia and oculomotor palsy may be both on the same side. The hemiplegia is gradual in onset and is usually more or less spastic. In some cases tremor or choreiform movements appear due to the pressure on the pyramidal tracts. Hemiataxia has been observed and both arms were ataxic in the case reported by the author. In rare instances palsy of the opposite limbs is observed, when, according to Oppenheim, dysphagia and dysarthria may occur. Contralateral hemianasthesia occurs in some cases and the reduction of the body temperature on the paralyzed side has also been noted in a few instances. Paresthesia and hemihyperesthesia have occurred. The reduction of body temperature may possibly be referred to vasomotor disturbances from implication of the substantia magna. Inordinate laughter was a symptom in two instances. Tuberculous tumors predominated, constituting twelve out of the eighteen. In three cases the tumor was a glioma and in one case a hard-celled sarcoma.

2. Traumatic Tetanus.—M. H. Gordon points out that Sawamura whose work is quite recent (1909) recognises three kinds of tetanus: tetanus ascendens, tetanus descendens, and mixed tetanus. In tetanus ascendens the local muscles are affected first; next the tetanus spreads up the limb, then to the opposite limb, and finally up the trunk. This is the form commonest in experimental animals after subcutaneous or intramuscular injection. It is possible, however, that this type is not as rare in man as may be supposed. Tetanus descendens appears to be the commonest form in man and the horse. The muscles of the jaw and neck are first affected and then the disease spreads down the body. It is of graver significance than tetanus ascendens. In mixed tetanus both the above forms occur. The patient's chance of life depends upon (1) the incubation period, (2) the rapidity of onset and severity of spasms, and (3) the duration of the disease. Of these points (1) is the most important and (2) comes next. In the words of Kanthack, "fatality is in direct proportion to rapidity of onset, and inversely proportional to the duration of the disease." As long ago as 1891 Vaillard and Vincent showed that when freed of adhering toxin either by washing or by heat neither *B. tetani* nor its spores produced tetanus in animals by simple inoculation. They found, however, that the toxin-free bacillus or spore could produce the disease if they bruised the tissues locally by pinching them with a forceps, or if they simultaneously injected either lactic acid or another microorganism such as *B. prodigiosus* or even its filtrate. These experiments are generally held to show the importance of bruising and also of a mixed infection in the genesis of tetanus. There is reason for doubting, however, if it is even now clearly realized how very important the associated bacteria may be. The author attributes an important rôle to the associated bacteria particularly in fatal cases. It seems probable that the explanation of the difference in prognosis according to the length of the incubation period is directly due to the association of *B. tetani* with other virulent bacteria of which the most important is the anaerobic bacillus of Welch. While tetanus antitoxin has been a brilliant success when applied prophylactically, and its efficiency in this sense is beyond question, there is no doubt that up to the present its employment after the onset of tetanus has proved disappointing. The conclusion which Roux and Borrel came to as the result of their experiments was that "a few drops of tetanus antitoxin in the brain cure tetanus better than large quantities introduced into the blood under the skin. It is not sufficient to give the antitoxin; it must be introduced in the right manner. There is a point in the disease, however, beyond which antitoxin is of no avail in whatever fashion it is employed. The intracranial injection lengthens the period of efficacious treatment." The question as to how to deal with the anaerobic bacillus of Welch when it is also present has not yet been satisfactorily solved. At the present time the best thing to do seems to be to give the wound as much drainage, free air, and premanganate as possible.

1. Treatment of Arthritic Deformities.—R. Jones states that in the case of ankylosis the joint should be allowed to become fixed in the position of greatest usefulness as regards function. In children most deformities can be corrected by manipulation, and osteotomies and exsection of bone are very rarely required. The reduction of the deformity in a septic or tuberculous joint during the existence of the disease can be safely undertaken if the reduction be immediately followed by fixation. In sound fibrous ankylosis of the hip an osteotomy should be preferred for the correction of adduction, as some recurrence of deformity would follow reduction by manipulation. The site of osteotomy will depend upon the nature of the ankylosis and upon the extent of the deformity. Transtrochanteric osteotomy gives the most accurate mechanical result. It should be practised in all cases of bony fixation where the femoral neck is not absorbed and where there is no marked pathological dislocation. In cases in which destruction of the head and neck have occurred and the femur lies close upon the pelvis a wedge should be removed from the neighborhood of the trochanter. In cases of fibrous ankylosis in the process of becoming sound a subtrochanteric osteotomy is indicated to prevent strain upon fibrous bands. All osteotomies require subcutaneous division of the abductors. Subtrochanteric osteotomy is contraindicated if flexion is extreme. Arthroplasty of the hip joint in any of its many forms may be looked upon as a valuable and successful procedure. The character of the intervening substance—whether bone, free or pedunculated fascial flap, fat, or muscle—is not as important as good technique and sound judgment. The operation should not be performed upon children or in the presence of active disease. It should be reserved for adult life, and has proved more successful after recovery from septic than after recovery from tuberculous disease. In the case of septic disease it should be postponed for one or more years until the periarticular structures have become more normal. The results of arthroplasty of the knee are not too encouraging. In bony ankylosis of the femur and tibia the results are discouraging. In the instances in which the ankylosis is fibrous, with perhaps bony fixation of the patella, the results are often good. In such conditions, however, mobility may often be secured without operation. Finally, in painful and progressive deformities, such as in osteoarthritis of the hip, there are many procedures destined to give relief by preventing the friction of tender joint surfaces.

2. Mechanical Considerations of the Human Foot.—H. S. Rowell notes that raising the heel of the ordinary shoe would have the effect of increasing instead of decreasing the tension on the supporting tissues. Raising the heel cannot in general have a beneficial influence in cases of incipient flatfoot. This conclusion is however only partly justifiable because investigation has been purely statical and cannot take account of the foot in motion. On the other hand, flatfoot occurs mostly in people who do a great deal of standing, so that it might seem rational to suppose that the causes producing the trouble are statical. These results are nowise affected by considerations of muscular tone except in the sense of corroboration. For if the muscles become flaccid the effect is to increase the stress on the large ligamentous fascia at the sole of the foot and in fact to approach more nearly the statical conditions of the roof-truss model. For long distant walking or long country walking high heels would be absurd because of the short strides which must be taken if the balance is to be convenient and sure. There is also the undoubted difficulty of avoiding undue pressure and constraint on the anterior part of the foot, but this is the bootmaker's

problem. For the ordinary inactive life of the drawing-room, office, and shop, high-heeled boots and shoes may be advantageous in giving to the feet a pleasant, braced-up feeling, quite different from that enjoyed or suffered by those who go about in heelless slippers.

Münchener medizinische Wochenschrift.

September 29, 1914.

Shortage of Imported Drugs.—Straub takes pains to acquaint the German practitioner with the exact source of each important drug, so that economy may be exercised in prescribing drugs imported from over sea. Aloes comes from South Africa and may be replaced by anthraquinone derivatives (crude drug, cortex frangulæ), by phenolphthalein, etc. Balsam of Peru comes from South America and may be replaced in some degree by synthetics or natural substances, which consist chiefly of cinnamic acid esters, from which artificial balsams may be made. Their value as substitutes for Balsam of Peru is as yet questionable. Medicinal camphor is protected by the enormous employment of the artificial substance. Peruvian bark and coca leaves can be obtained at present from Amsterdam, the regular distributing point, and most of the synthetic quinine comes from Germany. Should cocaine give out the so-called derivatives can be made by synthesis. Caffeine is made chiefly from uric acid. Hydrastin can also be made by synthesis. In the case of morphine a real famine danger is possible. The neutral countries have prohibited its export. This is about the time of year for the annual import. Morphine cannot be replaced, and must be used economically in every way. Never give it if something else can do the work. Use the smallest dose to get results. What is true of morphine is true of codeine. Castor oil may be obtained at present from the Italian import, and a poor quality from the varnish industry. Strophanthin may perhaps be replaceable by cymarin. Ergot may perhaps come to a shortage and cannot readily be replaced.

General Prophylaxis of Epidemics.—Rosenthal lays down a series of measures designed to avert the spread of pestilences. Use no unboiled drinks save wine, beer and natural mineral waters; avoid raw fruits; avoid physical overexertion; if unboiled water must be drunk, acidulate it with phosphoric or citric acid; wash the hands thoroughly before each meal; isolate every soldier with profuse diarrhea; inspect the manufacture of all mineral waters to make sure that raw water is not used therein; restrict the sale of spirits: in an infected or suspected district forbid the traffic in lemonade and other drinks, ices, etc., which contain unboiled water.

Deutsche medizinische Wochenschrift.

October 1, 1914.

Feeding the People in War Time.—Professor Rubner outlines the sources of England's food supply. She receives dairy products from Holland and the Scandinavian countries and also from Switzerland via France. From Canada she also receives cheese, while meat and cereals are mostly imported. England engages in manufacture and commerce rather than agriculture because gains are more rapid. With Germany it is otherwise. She has 11,000,000 cows and the daily per capita production appears to be sufficient for the needs of the consumer. Germany is naturally a great meat-eating country, consuming about 115 pounds annually per capita, about half of which is pork. War interferes somewhat with the supply of poultry, eggs, and fish, but not directly with the meat supply proper. Shortage in other directions should be readily made up from the markets of the neutral countries, which happen to include the very ones which have supplied England with poultry, eggs, and dairy products. In regard to cereals enough wheat and rye alone are raised in Germany to support the country. The potato crop this year has been very satisfactory. The percentages used as food cannot be increased by cutting down the manufacture of spirits, for alcohol may become in great demand to replace gasoline as fuel. Germany need not worry about the shortage of fruits and vegetables. The problem of animal fodder is not so simple, for this has ranked in part among the imports, but at present the country has three and a half million tons on hand, and as fodder material is much the same as the distillers' raw material, some diversion of supply from man to animal is possible. In regard to brewing, animals get the refuse while man gets the nutriment in the beer. If pigs, for example, are fed directly with barley, but a small production of the food value of the latter is realized in the gain of weight by the animal, for the latter uses up most of it as mere fuel. The people will have plenty of opportunity for economizing by cutting down the meat consumption, by eating the coarser forms of bread, by restrictions on the use of butter and sugar, by using the cheaper milk products (buttermilk, curds), by eating more legumes, etc., etc. This self-denial naturally has the effect of lowering the market prices.

Introduction into Military Surgery. — Czerny cites some of the surgical consequences of the war up to the close of the first six weeks. Many wounded were sent to Heidelberg, presumably those most capable of transportation. But 27 deaths have occurred and of this number 8 were due to tetanus. The total number of tetanus victims was 17. The nine survivors are out of danger. This is a remarkable mortality percentage—less than 50 per cent—and perhaps cannot be justly attributed to the treatment which as a rule consisted of antitoxin and the usual sedatives and narcotics. One patient did not die directly of tetanus, but of a double pneumonia after cessation of convulsions. As in the majority of cases tetanus followed shell wounds, an investigation was made of the latter but thus far the tetanus bacillus has not been found. There has not been on hand enough antitoxin for prophylactic use but it will doubtless become the custom in time to treat suspicious wounds with this drug in powder form. Wounded men should not be transported in cars which have been used for horse transport. In addition to tetanus, infection of wounds occurs and gives a mortality. Thus far ordinary and gas phlegmons, blue pus, sepsis, and pyemia have furnished their quota of sickness, but erysipelas and hospital gangrene have not yet appeared.

Military Surgeons' Evenings at Berlin.—At one of these gatherings Jochmann discussed the subject of tetanus in the German Army. The disease is the result of the injurious action of the tetanus toxin on the motor ganglion cells of the brain and cord. These centers are reached through migration of the toxin along the axis cylinders. Naturally the shorter the nerve trunk the more rapidly are the motor ganglion cells reached. Thus, the toxins enter the blood and thence the axis cylinders. The ganglia of the motor nerves of the muscles of the face, jaw, neck, esophagus, etc., are most rapidly reached and give rise to the primary symptoms — lockjaw, opisthotonos, etc. The author illustrated the clinical phases of the disease by epidiascopic pictures. The toxin must be antagonized, first in the blood, then in the nerves, and finally in the ganglia. To attain this end we inject antitoxin intramuscularly and also into the spinal canal. Magnesium sulphate should also be used in routine by the subcutaneous route.

Insurance Medicine.

SUGGESTIONS TO MEDICAL EXAMINERS.

BY THE INSURANCE EDITOR.

THE DETENTION AND SIGNIFICANCE OF SYPHILIS.

ALL doubt must be removed, as far as possible, as to whether each applicant has or has not been afflicted with syphilis, and that he is free from all traces if he happens to have been the victim of a previous luetic infection. This task is often difficult as the examiners are obliged to depend upon the history, negative or positive, given by the applicant. Certain indications of former lesions or some obscure signs of a latent form of the disease are present at times, however, and may be discovered by a close and careful examination. The secondary stages leave no outward signs such as scars, though successive attacks of iritis may follow the secondary as well as the tertiary stage, and should lead to a close questioning of the applicant with this point in mind. The tertiary lesions are distinguished, among other manifestations, by their tendency to ulcerations which are followed always by scars. These ulcerations occur most frequently on the legs and at points where the bone is directly covered by skin and are not uncommon on the hand and soft palate. Destruction of the nasal bones resulting in a sunken bridge should lead to a presumption of syphilis, unless there is given a history of traumatism.

The diseases due to syphilis which most commonly cause death are affections of the heart and vascular system, aneurysm, general paralysis, locomotor ataxia, diseases of the central nervous system, chronic nephritis. Fournier furnishes statistics based on the observation of 2395 cases, in which the date of invasion of tertiarism could be determined exactly. There were 106 cases in the first year, 227 in the second year, 256 in the third, 229 in the fourth, 205 in the fifth, 201 in the sixth. The total in the first six years was 1224. From the sixth to the tenth year there were 499, from the tenth to the twentieth, 543. Above the twentieth, 129. These estimates show that if tertiary symptoms follow, they will occur in more than one-half of the cases in six years, and in nearly 75 per cent. in ten years, facts which are somewhat opposed to the popular idea that a very large proportion of the late effects of syphilis manifest themselves a long time after the appearance of the initial lesion.

The vital statistics of the United States Census Bureau, according to Hyde, make it seem probable that the fatality *directly* from syphilis is about 2 per cent. Runeberg, on the other hand, found that 11 per cent. of 734 deaths among insured persons were due to diseases resulting from syphilis, and that if certain apoplexies, probably syphilitic, were included, the mortality was 15 per cent. of the total. We have pointed out in another place that the Medico-Actuarial Investigation Committee found a mortality of 188 per cent. among insured persons who had been thoroughly treated for syphilis, the diagnosis having been certain.

These figures assume added importance from the fact that they represent the mortality among insured persons selected with care from the general population. The high percentage of mortality among those who have had syphilis cannot be attributed directly to the disease itself or to parasyphilis in a large number of cases, as the damage done by syphilis consists largely in the lowering of the general health, making the subject more vulnerable to other diseases. Furthermore, the vitality and resistance to attacks of other diseases and injuries, and the recuperative powers, are badly undermined.

It becomes the duty, then, of every examiner to scan the body closely for scars, tertiary syphilis, destruction of bone and other tissues for remaining indications of the disorder. Furthermore, every applicant should be subjected to the well-known tests for the detection of the mental disorders, cerebral and spinal lesions and changes in the vascular system, which have become so prominent as causes of death among policyholders. The fine tremor of the tongue, which is one of the very first signs of general paralysis of the insane, is usually overlooked. The pupils should be scrutinized as a part of every examination, for the possible existence of the Argyll-Robertson pupil. Ptosis with external strabismus and dilatation of the pupil, is due to paralysis of the third nerve, and is significant of tertiary syphilis. The patellar reflexes should be tried out and the test for Romberg's symptom applied. If the case looks suspicious, Babinski's reflex should be sought for. The applicant should always be asked to walk so that the gait may be observed. High blood pressure in many cases is an indication that the vascular system has become involved. Thickening and hardening of the radial or temporal arteries in applicants under middle age may usually be attributed to syphilis.

Looking forward, the time may come when the practice of directly demonstrating the presence of the *Spirochæta pallida* in all suspicious venereal sores by the means which have been placed at our disposal by the serologists, will become so universal that applicants will be in a position to furnish actual proof of the nature of the lesion when they apply for insurance later on.

Some Helpful Hints Gathered in Court.—The medical director must know that in the jurisprudence of life insurance his work has its effect and he should be informed that much that comes to him from company management and field endeavor is highly important when company and agent are in court. The law is a part of every contract of insurance as much as if written therein at length. (Metropolitan Life vs. Johnson, 94 N. E. 785). Ordinarily the medical director may take his time in passing upon an application, but he may not unreasonably delay action. (Mutual Life vs. Neafas, 140 S. W. 1026.) "Are you in perfect health so far as you know and believe?" Answered in the affirmative covers only the one inquiry and cannot be made to relate to any preceding details regarding health. (Blenke vs. Citizens' Life, 140 S. W. 561.)—Thomas W. Blackburn, secretary and counsel, American Life Convention.

The Question of Contact with Infectious Disease.—A question on which there is little authority was determined in the North Carolina case of Gardner v. North State L. Ins. Co. 48 L.R.A.(N.S.) 714, which holds that denial in an application for life insurance of intimate association with anyone suffering from any transmissible disease within a year avoids the policy if the applicant had within that time nursed members of his family ill with typhoid fever.

Book Reviews.

A Handbook of Fevers. By J. Campbell McClure, M.D. (Glasgow), Physician to Out-Patients, the French Hospital, London, and Physician to the Margaret Street Hospital for Consumption and Diseases of the Chest, London; formerly Senior Resident Assistant Physician, Assistant Superintendent, and Resident Medical Officer in Charge of the Smallpox Hospital, Belvidere Fever Hospital, Glasgow. London: Shaw & Sons, 1914.

This volume is devoted to a description of the various infectious fevers, the practical aspects of the latter, particularly the treatment, being emphasized. The classification is as follows: Fevers of known bacteriology: enteric fever, diphtheria, the plague, cholera, relapsing fever, malaria, epidemic cerebrospinal meningitis, anthrax, glanders, influenza, pulmonary tuberculosis, dysentery, and kala azar. Fevers of uncertain bacteriology: scarlet fever, measles, German measles, smallpox, chicken-pox, typhus, mumps, rheumatic fever, yellow fever, and whooping cough. Acute diseases frequently attributed to a diet consisting largely of certain cereals: beriberi and pellagra. An introductory chapter gives an excellent description of certain details in the management of the patient which are common to all the infectious diseases. In the treatment of typhoid fever the author emphasizes the importance of an adequate amount of carbohydrate in the dietary and alludes to the value of a raw egg mixed with the milk in prolonged cases with much wasting. The author rightly advocates the use of single large doses of six to twenty thousand units of antitoxin in the treatment of diphtheria. One may question, however, his condemnation of intubation as a routine procedure in the treatment of diphtheritic stenosis of the larynx. The author's opinion on this subject may be quoted in full: "Intubation has been urged by many as a substitute for tracheotomy in many cases. It is possible that in skilled hands and in hospital practice it may be attended with small risk, but even under these conditions, where the tube, if dislodged, can be quickly replaced by the physician in charge, intubation has frequently to be followed by tracheotomy. In private practice it is not to be recommended. The operation requires a considerable amount of training and manipulative dexterity, and one cannot expect a nurse to replace a dislodged intubation tube, so that the proximity of the practitioner is necessary to a degree impossible for one engaged in a practice of any size. After tracheotomy, on the other hand, the tube, if dislodged, can be replaced by any nurse who has had an ordinary training in fevers, and the practitioner is able to do his work properly without the danger of impossible calls on his time. The objections to intubation in this way are very practical and the operation has not taken hold in this country for these reasons. However, if a practitioner is able to devote the time necessary to one patient, intubation will be found, in a certain number of cases, to obviate the need of tracheotomy, when otherwise the major operation would have to be performed." The answer to this argument may be stated simply as follows: If the practitioner cannot give to his patient the requisite degree of skill and vigilant observation that intubation requires then he should summon a colleague capable of giving this skill and observation or should place his patient in a hospital where these are available. Of course, tracheotomy may be necessary as an emergency operation which no practitioner should hesitate to perform. On the whole, this volume may be characterized as a clear, practical exposition of the latest knowledge of the infectious fevers. The typographical and other mechanical features leave nothing to be desired.

The Art of Compounding. A Textbook for Students and a Reference Book for Pharmacists at the Prescription Counter. By Wilbur L. Scoville, Ph.G., formerly Professor of Theory and Practice of Pharmacy in the Massachusetts College of Pharmacy; Member of the Eighth Committee of Revision of the United States Pharmacopeia and of the Second and Third Committees of Revision of the National Formulary. Fourth Edition, revised and enlarged, with 76 illustrations. Price $3.00 net. Philadelphia: P. Blakiston's Son & Co., 1914.

Comparatively few physicians have even a superficial knowledge of the art of compounding. Familiarity with the methods employed by the pharmacist will go a great way toward correcting a rather widespread chaos in prescription writing. The present volume is one that should find a suitable place in the doctor's library. It is strictly up-to-date, including such subjects as colloidal chemistry, the preparation and use of ampoules, physicochemical studies of emulsions, the "phase rule" in the liquefaction of mixtures of ketones and phenolic bodies, improvements in ointment bases, pharmaceutical applications of sterilization, and biological products. Of particular interest are the 225 prescriptions which have been culled from State Board Examinations and which have been arranged under the various classifications. The prescriptions illustrating different types of incompatibilities, with notes explaining fully the nature of the incompatibility, should prove of distinct service to the prescriber. This volume contains a large number of illustrations showing chiefly the manufacturing side of pharmacy. There can be no hesitation in recommending this book to the practitioner, although it is designed primarily for the pharmacist and the pharmaceutical student.

Psychopathology of Everyday Life. By Prof. Dr. Sigmund Freud, LL.D. Authorized English edition by A. A. Brill, Ph.B., M.D. Price $3.50 net. New York: The Macmillan Company, 1914.

This is a translation of another of Freud's works by his American pupil. In this work the doctrines of the German psychiatrician are developed and extended to the casual acts and thoughts of everyday life in a manner which is at least highly ingenious. The themes are developed with an appearance of logic, but the argument is often obviously forced and in many instances not at all convincing. This is, however, not the time or the place for a critical discussion of the theories. It is sufficient to say that the book represents Freudism carried to an extreme, but in the most attractive guise possible.

Progressive Medicine. A quarterly Digest of Advances, Discoveries and Improvements in the Medical and Surgical Sciences. Edited by Hobart Amory Hare, M.D., Professor of Therapeutics, Materia Medica and Diagnosis in the Jefferson Medical College, Philadelphia; Assisted by Leighton F. Appleman, M.D., Instructor in Therapeutics, Jefferson Medical College, Philadelphia. September, 1914. Price, $6.00 per annum. Philadelphia and New York: Lea & Febiger.

The September number contains contributions by W. Ewart, on Diseases of the Thorax and its Viscera, including the heart, lungs and bloodvessels; by W. S. Gottheil on Dermatology and syphilis; by E. P. Davis on Obstetrics; and by W. G. Spiller on Diseases of the nervous system. All of these writers are experienced hands, and the readers of this quarterly are familiar with their able presentation of the subjects entrusted to them.

The Cause of the Social Evil, and the Remedy. By Albert W. Elliott, President and General Manager, The Southern Rescue Mission, Atlanta, Ga.: Webb and Vary Co., 1914.

This little pamphlet is the work of one who has devoted several years to rescue work. He writes from what he knows, and has seen for himself; and his treatment of the question differs from almost all other writings on the subject by his wide sympathy and equally broad common sense. We strongly recommend this booklet to all interested in the subject of which it treats; it will prove a useful antidote to the larger and more pretentious works which are frequently the outcome of much zeal, little charity, and less knowledge.

A Manual of Normal Histology and Organography. By Charles Hill, Ph.D., M.D., Professor of Histology and Embryology, Chicago Veterinary College, formerly Assistant Professor of Histology and Embryology, Northwestern University Medical School, Chicago. Third edition thoroughly revised. Price, $2.25 net. Philadelphia and London: W. B. Saunders Company, 1914.

There is very little difference between this edition and the one which preceded it. The new matter consists mainly of a few paragraphs on the stomach in ruminants, and on the hoof of the horse. The volume is one of the best of the smaller works on histology; the main facts of the science are presented concisely and with suitable illustrations. The cloth binding is an improvement on the leather cover of the last edition.

Society Reports.

MISSISSIPPI VALLEY MEDICAL ASSOCIATION.

Fortieth Annual Meeting, Held at Cincinnati, October 27, 28, and 29, 1914.

THE PRESIDENT, DR. D'ORSAY HECHT OF CHICAGO, IN THE CHAIR.

Factors Which Determine the Advisability of Prostatectomy.—Dr. WILLIAM F. BRAASCH of Rochester, Minn., drew the following conclusions: 1. "With stone in the bladder it is usually advisable to remove the stone and drain the bladder for a time prior to prostatectomy. 2. Stone in the bladder may cause temporary enlargement of the prostate. 3. Pyelonephritis is a frequent complication of bladder drainage and a strong resistance should be established before attempting operation. 4. The renal condition is better estimated prior to operation by clinical evidence than by laboratory tests. 5. Cystoscopic examination, while valuable in certain conditions, may be the cause of harm if used as a routine procedure. 6. Urethroscopic examination is occasionally of greater value than cystoscopic examination. It is particularly valuable with intraurethral hypertrophy and with carcinoma."

Hemolysis Following Transfusion of Blood.—Dr. BERTRAM B. BERNHEIM of Baltimore said that having had one fatal case of hemolysis following an emergency transfusion of blood and one non-fatal case following a transfusion for therapeutic purposes, he sent out a question form to various men throughout the country with the view of ascertaining just how frequently hemolysis did occur following transfusion, and what were the consequences. Briefly, he found that in eight hundred reported transfusions there were fifteen instances of macroscopic hemolysis, an incidence of about 2 per cent. In these fifteen cases there were eleven recoveries and four deaths. No hemolytic tests were made in three of the instances where death occurred, although there was plenty of time to do so in two of the cases. The third was Bernheim's own case, which was a postoperative emergency where there was no time. In the fourth death tests were made and it was known that the "donor's cells were slightly agglutinated by the patient's serum," but since agglutination was an entirely different process from hemolysis, and since no other donor was available it was considered fairly safe to use this donor, and a fatality occurred. Tests were made in eleven of the fifteen recoveries, and in nine instances hemolysis was prognosticated. That there were no fatalities in this group was considered almost a miracle, as he felt that his study showed and proved the value of the blood tests. He divided the dangers of transfusion into the immediate and the late or delayed dangers. The first or immediate was acute dilation of the heart consequent upon an inflow of blood of such force and rate that the recipient's heart was overwhelmed. A definite train of signs and symptoms indicated such a condition, which could always be recognized and avoided by the careful operator, especially if he was experienced in this line of work. The late or delayed danger was that of hemolysis, which could be prognosticated in practically every instance by careful tests prior to transfusion. He felt that in the emergencies no thought should be given to hemolysis or anything else. Far better was it to transfuse immediately and save a patient from imminent death, running the slight risk of a late hemolysis, than to temporize with tests which required at least two hours, even under the most propitious circumstances, for their proper performance, during which time the last flicker of life might disappear. Where, however, there was time, and in the majority of instances such was the case, failure to have the tests done was an inexcusable blunder. The majority of bad results were not reported, and he knew of numerous instances of hemolysis which, for one reason or another, he could not include in his study; so that, instead of an incidence of 2 per cent., the true incidence of hemolysis would probably be at present nearer 4 per cent. And practically all of it could be prevented.

Radium in the Treatment of Cancer of the Uterus.—Dr. J. LOUIS RANSOHOFF of Cincinnati said that radium was of undoubted value in cancers of the uterus, at any and every stage of the disease. The control of hemorrhage, discharge, and pain was undoubted. The radium had a beneficial local action resulting in the local disappearance of the disease, in every instance. The question as to whether radium had a permanent curative effect on cancers of the uterus must be left to the future to decide, as a large number of permanent cures was necessary before the claims of radium could be substantiated. The same might be said of the use of radium in operable cases. At present, if possible, radium should be used in all cases of inoperable cancers of the uterus when the patient was not in the extreme stage of emaciation and cachexia. If the promises of radium in the treatment of cancers of the uterus were substantiated by permanent cures, radium might, in the future, entirely supplant operation, unless improved technique decreased the large operative mortality and promised a higher per cent. of radical cures.

Renal Infections from a Bacteriological Point of View.—Dr. IRVIN S. KOLL of Chicago said that to consider properly the bacteriology of renal infections, one must take into consideration the various factors that acted as contributory to the passage of the pathogenic bacteria into the kidney. The relative importance of the now accepted three routes, lymphogenous, hematogenous and urogenous, offered considerable interest. Our present definite knowledge of the lymph channels draining from the intestinal tract into the kidney readily accounted for the frequency of infections of the kidney associated with acute and chronic gastrointestinal disturbances. Infections through the ureter might be either extra or intraureteral. Of particular importance was the pyelitis associated with pregnancy, the frequency of which was estimated as high as twenty per cent. by some obstetricians. Of late the hematogenous route seemed to have been neglected in the consideration of the carriage of bacteria to the kidney. Its importance, however, should not be underestimated, as there could be no doubt that the circulatory system as a carrier of bacteria was of as great importance as the lymph stream. Three factors should be recognized in arriving at a diagnosis which would give a basis for a rational treatment: What was the contributing cause? What was the invading organism? What was the pathology—pyelitis, pyelonephritis, or pyonephrosis?

Experimental Studies in the Production of Chronic Gastric Ulcer.—Dr. WALTER W. HAMBURGER of Chicago said that he believed he had reproduced experimentally in dogs chronic ulcer of the stomach in a way strikingly similar to the clinical syndrome in man. While it was dangerous to draw parallels from artificial conditions in animals to clinical disease, in this instance certain conclusions seemed justifiable. If one was permitted to picture a human ulcer from the standpoint of these experiments, it might appear that slight abrasions of the mucosa, hemorrhagic erosions or even small acute ulcers occurred frequently in the human; that these acute lesions might result from food traumatization, emboli, or bacteria; that under usual conditions these acute lesions healed promptly with little or no evidence of their having occurred; that under unusual conditions, however, for instance the presence of hypersecretion and hyperacidity from the underlying neurotic cause—vagotonia; the presence of motor insufficiency from recurring pyloric spasm from swallowed toxic material and reflex pyloric spasm from disease of the appendix, gall-bladder, or elsewhere; the presence of delayed motility from low-lying atonic stomach, enlarged liver or kidney; distended gall-bladder, pancreas or colon—that under these unusual conditions these acute ulcers were prevented from healing and became chronic. As a matter of clinical experience such conditions were frequent attendants of chronic ulcer and were important causative and propagating factors. From this viewpoint they were of the utmost significance and prophylaxis.

Gastric and Duodenal Ulcer: Etiology, Diagnosis, and Treatment.—Dr. C. W. DOWDEN of West Baden, Ind., reported a statistical study of four hundred and twenty-five cases of gastrointestinal disturbances, in which a diagnosis of gastric or duodenal ulcer seemed warranted from a thorough examination, including the various laboratory methods and the employment of the Roentgen rays. Of this number, one hundred and seventy, or 40 per cent., bore a definite relation to some infection, and he concluded that this was the chief etiological factor. The anamnesis and the Roentgenological findings were the most important diagnostic methods, but the various laboratory procedures were valuable aids, particularly for outlining appropriate treatment. He believed that ulcers passed through a stage which was distinctly medical, and if diagnosed at

this time were amenable to treatment. Surgical ulcers were those that had involved more than one coat of the gastric mucosa and could always be demonstrated on the radiograms. Medical treatment at this time was worse than useless because the patient mistook temporary relief for cure, and finally suffered one of the several sequelæ, the most frequent and serious of which was carcinoma. In proof of the theory that pain was not a result of irritation by hydrochloric acid, he cited several cases and showed Roentgenograms, in which all symptoms of ulcer were present, but the gastric analyses showed a total absence of hydrochloric acid. That pain was a result of hyperperistalsis and tugging on the peritoneum he thought was a more logical conclusion. He believed a new era was dawning and that further study would show us that an active ulcer in its early stage was best treated by absolute rest to the stomach, by keeping it empty, and thus avoiding the possibility of carrying infections per os, controlling painful peristalsis by anti-spasmodics, preferably atropin, and by rectal feeding until the acute stage had passed. All foci of infection, no matter where located, should be removed.

Dr. CHARLES D. AARON of Detroit stated that in the treatment of gastric ulcer he had found that when it was complicated by vagotonia, the treatment of ulcer plus the treatment of the vagotonia would give a better result than if we ignored the vagotonia, and by our present physiological and pharmaco-dynamic tests for vagotonia, which was easily done in ulcer of the stomach, we could then tell whether the neurotic process should receive treatment or not. This was one side of the question. All had had healed cases of ulcer of the pylorus, with contraction at the pylorus, stenosis of the pylorus, dilatation of the stomach, and the visible peristalsis recognizable when the stomach was endeavoring to empty itself, trying to overcome obstruction of the food, working backward and forward on the mucous membrane, endeavoring to get through the part, the patients vomiting, and to relieve themselves temporarily would eat a crust of bread. There was a similar process going on in a patient who was becoming emaciated, weak and run down, and anemic. We submitted the patient to surgery, and what was found? We found no ulcer of the stomach. We found obstruction of the pylorus, a gastroenterostomy was done, and the patient recovered. Why in such cases did we not have chronic ulcer of the stomach?

Dr. CHARLES A. L. REED of Cincinnati stated that one thing that had impressed him in connection with these papers was the little regard that had been paid to one of the most important of the etiological factors, namely, chronic intestinal stasis. There was too little attention given to the conditions within the stomach proper, to the nerve conditions back of the stomach action, and to the various distinctly local causes as they applied directly to the pylorus or to the duodenum, but he thought if one fact had been demonstrated with more conclusiveness than any other in latter day surgery, it was in the majority of cases we found that the difficulty lay in favor of normal physiological drainage of the duodenum and stomach, thus inducing infection which in turn induced ulceration. He had succeeded in demonstrating this to his complete satisfaction in a considerable number of cases, whereas in his earlier practice he followed the then prevailing method of operating by posterior gastroenterostomy. He had latterly tried to establish drainage in the lower segment of the intestinal tract, and with what results? There was a normal physiological drainage of the duodenum; we had normal physiological drainage of the stomach if the pathological process had not already gone too far and certain direful results had become established, and when we succeeded in getting normal evacuation of the lower bowel or in doing away with intestinal stasis, we were getting normal physiological drainage by which the ulcer disappeared.

Dr. W. D. HAINES of Cincinnati said that in the class of cases under discussion we had been operating in the past on end results; we had not been seeking the cause.

Dr. HAMBURGER, in closing the discussion on his part, pointed out that in the ulcers which healed, the acidity values were low, and there was not much evidence of dilatation or hypertrophy of the stomach wall. Where he had the greatest hypertrophy or greatest dilatation he usually got the greatest amount of ulceration.

Dr. DOWDEN in closing said that he was fully in accord with everything Dr. Reed had said as to the important rôle intestinal stasis played in the production of gastric and duodenal ulcer.

Presidential Address: The Public and the Profession; a Criticism.—Dr. D'ORSAY HECHT of Chicago delivered this address. (See page 867.)

Colon Stasis.—Dr. JOSEPH R. EASTMAN of Indianapolis said that it seemed fair to say that treatment directed at the relief of chronic colitis would affect also the attendant ptosis and stasis and likewise the associated plastic peritonitis. Properly performed short-circuiting operations by the improved drainage which they provided or should provide relieved chronic colitis and indirectly affected favorably the other factors of stasis, ptosis, and peritonitis. It was well known that the feces was to a considerable extent made up of epithelial debris of intestinal secretions and of dead and living bacteria, and that these things mixed with food residue under the influence of contractions of the cecum rose in the ascending colon. But this contraction was not constant. The empty cecum was in repose; it did not contract. It was only awakened when the small intestine emptied into it its liquid contents. It was this irritant which provoked the contractions. If contractions were not produced in this way, the feces composed of epithelial debris, mucus, and bacteria had no tendency to be evacuated. The colon became lazy and atonic and obstipation was increased by antiperistalsis. It was for this reason that ileosigmoidostomy might be said to be falsely conceived. By this operation the liquid contents of the small intestine were not permitted to enter the cecum to bring about contraction. It was for this reason that Lane, Leriche, and others had been obliged to reoperate after ileosigmoidostomy and dealt with an enormous fecal accumulation in the cecum and ascending colon. It was clear that typhlosigmoidostomy or typhloproctostomy could not be opened to the above criticisms, for in these operations the fluid contents of the small intestine were permitted to enter the cecum. In a case of simple constipation concerning only the left colon, ileosigmoidostomy might be of some benefit, but it was debatable whether such a condition was not better treated by nonsurgical means. Bergmann first anastomosed the cecum to the sigmoid for volvulus of the ascending colon and the operation in cases of stasis was not indicated unless membranes or adhesions so fettered the colon as to make such an exclusion necessary because of incompetency or obstruction. If the colon was obstructed at the hepatic or splenic angles alone, then colocolostomy, as practised by Payr, which excluded these flexures alone was of obvious use. Sigmoidoproctostomy for the exclusion of redundant sigmoid might be often employed with advantage to supplement the anastomosis of the caput coli to the rectum or the redundant sigmoid might be treated by the Troyanoff-Winiwarter anastomosis between the loops of the sigmoid or eventually the redundant colon might be resected. At any rate, after typhloproctostomy, coils of redundant sigmoid could not with safety be left above the stoma. Montprofit's operation of dividing the terminal ileum and anastomosing both ends end-to-side with the sigmoid represented no improvement over simple typhloproctostomy. Here an attempt was made to drain the excluded cecum in defiance of the ileocecal valve through the short stump of the ileum, whereas this could be accomplished more simply and more completely by a large stoma in the floor of the cecum.

Dr. JOSEPH RANSOHOFF of Cincinnati stated that colon stasis existed without any question, but in a large number of individuals in which it existed, it produced no deleterious results whatever. There was a very small number of cases in which colon stasis was actually followed by conditions that were pathological. It had been said that idiopathic epilepsy might be brought on by colon stasis. It was a tremendously far cry from colon stasis to epilepsy. Idiopathic epilepsy was a condition which began exceedingly early in life in the form of petit mal. We knew that epilepsy was observed in children as early as the second or third year in some form or other. By no stretch of the imagination, by no amount of argumentation, could he believe that there was any possible connection between colon stasis and epilepsy.

Dr. WILLIAM SEAMAN BAINBRIDGE of New York said, that if there was one thing that Mr. Lane emphasized it was this, that nineteen cases out of twenty of intestinal stasis ought never to be operated on, and yet today all over the world men were saying that Lane performed colectomy, iliocolostomy, etc., on this class of patients, but if you analyzed carefully all he had written and what he had said over and over again, you would find that he hesitated about operating on certain cases. There were patients who had gone from New

York to London with their pocketbooks full of money to have their colons short-circuited or removed, but had come back to his positive knowledge to New York, living on Fifth Avenue, with belt on and plenty of Russian oil in their trunks, and some being taken every day.

Dr. Louis J. Hirschman of Detroit stated that he thought it was just as important to mention the non-surgical treatment of intestinal stasis as the surgical before a mixed body of this kind. Postural treatment, special localized exercise, etc., would cure many cases of intestinal stasis. We gave these patients Russian oil for months; it lubricated the stools, hastened their expulsion, and cured many of these cases. When they did not respond to these methods of treatment, as a final resort he fixed the plumbing.

Dr. J. Rawson Pennington of Chicago said that colon stasis was not a disease, but a symptom of a condition. Dr. Eastman had told us that by constricting the anus of a rabbit he was able to produce colon stasis. The treatment for colon stasis was to remove the constriction, and then the stasis disappeared. It did not make much difference what operation one did.

Functional Tests.—Dr. J. T. Geraghty of Baltimore stated that the necessity for functional renal tests arose from our inability to always recognize the presence of renal disease, and, above all, our inability to recognize the extent to which the presence of renal injury interfered with the function of the organ. On account of the great number of functional tests now proposed, it became necessary to know which tests were the most useful for practical purposes. In true nephritis they had found that the phthalein test in combination with a blood urea estimation, furnished practically all of the information which could be derived from these functional studies, except in rare instances. Chloride estimations were useful in a special group. For cases of urinary obstruction, the phthalein test was incomparable and only when the phthalein excretion was very low was it necessary to have a blood urea estimation. The presence of a high blood urea and a very low phthalein should contraindicate operation and called for more protracted preliminary treatment. For estimation of function in association with ureteral catheterization, the phthalein test was the simplest and furnished the most accurate information. A considerable increase in the blood urea only occurred in the presence of rather severe bilateral renal disease. While functional tests were extremely valuable and supplied data frequently unavailable from any other source, it should be remembered that they revealed only the excretory capacity of the kidney. By themselves they did not make the diagnosis or supply the prognosis. They only indicated the functional value of the kidney at the time at which the test was performed, but could not by themselves indicate what the renal function would be tomorrow or next week. This latter information must be derived from the knowledge of the underlying pathological process which was producing the reduced function. Functional tests should always be used in conjunction with careful clinical studies.

Observations Upon the Use of the Abderhalden Reaction with Normal and Pathological Serums.—Drs. Ellison L. Ross and H. Douglas Singer of Kankakee, Ill., said, that in a previous paper they proved that the blood serum of normal animals contained ferments capable of splitting substrates prepared from the organs of animals of the same species. A series of tests demonstrated that this was also true for human serum and substrate. Furthermore, the material split up by the ferment could be entirely washed out by the substrate by repeated washing with acidified water. Investigations were then made with serum from pathological conditions and it was shown that by washing testicular substrate 20 times dementia precox serum gave consistently negative results. A comparison between the proteolytic power for brain substrate of the blood serum from general paralysis and that from normal persons was then made at different stages of washing. It was found that normal serum failed to react when the material was washed 5 times, whereas paretic serum showed a gradually diminishing ferment activity and became entirely negative at, and after the 13th washing. The results might be briefly stated as follows: (1) Paretic serum. With 2 washings 10 serums all gave positive results; with 3 washings 6 were all positive; with 5 washings 8 of 11 were positive; with 10 washings 1 of 3 was positive; with 11, 2 of 8; with 13, 14, and 15 washings none of the 20 were positive. (2) Normal serum. With 2 washings 8 were all positive; with 3 washings 1 of 4 was positive; with 5, 8, 10, 11, 13, 14, and 15 washings a total of 34 serums all gave negative results. It was also demonstrated that, just as with animals, the water used for the washing of substrates contained material which underwent lysis when mixed with blood serum. Hence, in order to determine whether there was any specific difference between the ferments present in general paresis and the normal state, the water used for the 5th and 8th washings was concentrated and used as a substrate. It was found that, in spite of the failure of normal serum to digest brain substrate which had been washed 5 times or more, normal serum caused lysis of the material in this washwater fully as markedly as did that from cases of general paralysis. From these facts the following conclusions seemed justified: (1) No interpretation of the results of Abderhalden tests with tissue substrates was justifiable unless the same (not merely similarly prepared) substrate had been proven to give negative results with a series of normal serums. (2) Tissue substrates could be washed from material capable of digestion by ferments present in normal and pathological serums. (3) There was a difference between the ferment activity of the serum from normal persons and those suffering from general paralysis of the insane as regards lysis of brain substrates. (4) This difference appeared to be quantitative rather than qualitative.

Modern Syphilis Therapy and the Central Nervous System from a Biological Point of View.—Dr. Carl D. Camp of Ann Arbor, Mich., stated, that the treatment of tabes and paresis was probably the most important part of the treatment of syphilis of the nervous system. These diseases, while due to syphilis, had other determining factors. Intravenous injections of salvarsan had an effect in some cases. Intradural injections of salvarsan had greater effect on the spinal fluid findings but were distinctly dangerous. The Swift-Ellis treatment seemed to vary in effectiveness with different observers; the more conservative did not find any greater improvement than with intravenous injections. The rationale of this treatment was not very clear. The use of mercury by injections was probably as effective as any method of treatment we had at the present time and had less possibility of harm. Cases of tabes dorsalis frequently became stationary under mercurial treatment, the spinal fluid findings either showing improvement or else no change.

Certain Physical Signs Referable to the Diaphragm and Their Importance in Diagnosis.—Dr. Richard Dexter of Cleveland, Ohio, said, that the situation of the diaphragm made it possible for the structure to be involved frequently in diseases of the organs either immediately above or below it. This involvement would often be demonstrated by very definite physical signs. Conditions which involved the diaphragm might be divided into two groups: (1) Those in which the symptoms of involvement depended on the irritation of the nerves which supplied the diaphragm. (2) Those cases in which the position of the diaphragm was affected. The result of this was that the diaphragm was put on a greater or less mechanical advantage. Irritations of the pleural or peritoneal coverings of the diaphragm gave rise to symptoms at a distance from the structure. The paths of pain distribution conformed to type of the viscerosensory reflex in the sense of Mackenzie and Head. Further confirmation of this view was to be found in the view of Capps. He reported two cases illustrating the pain distribution in diaphragmatic irritation, one in which no lung involvement could be made out, which might have been considered as an acute condition within the peritoneal cavity had not the evidence of diaphragmatic irritation been noted. Pain in such inflammations of the diaphragm was referred along the phrenic nerves and transmitted to the third or fourth cervical segments or along the sixth to the twelfth intercostal nerves to the lower dorsal segments. The inspiratory contraction of the diaphragm tended to draw the subcostal angle toward the median line. Under normal conditions this contraction was not strong enough to overcome the antagonistic action of the scalene and intercostal muscles. When the position of the diaphragm was lower than normal the contraction of the muscle would be more direct, and would, therefore, equalize or overcome the action of the scalenes and intercostals. The result would be a retraction of the costal angle toward the median line during inspiration. The best method of demonstrating the movements of the subcostal angle was described, and he reported cases indicating the diagnostic value of this sign. If

the diaphragm was pushed up from below the power of its contraction would be lessened with the result that the subcostal angle would depart farther from the median line than usual. He also pointed out the importance of the symptom in diagnosis.

Röntgenoscopy of the Colon with Special Reference to Some Sources of Error in Diagnosis.—Dr. JAMES T. CASE of Battle Creek, Mich., stated that the colon was normally subjected to certain variations in form and position and in the disposition of its contents which were entirely physiological. The large pendulum movements first described by Rieder were especially active in changing the form and position of the transverse colon. The appearance of the bismuth-filled bowel underwent numerous changes within twenty-four hours and from hour to hour on account of the influence of the different kinds of peristaltic movements to which the colon was subjected. With increasing experience, morphological factors had shrunk in importance, whereas functional problems relating to the colon had assumed greater significance. An increasingly large number of symptoms formerly attributed to ptosis were now found to be due to other more tangible lesions. It was especially important for the roentgenologist to familiarize himself with the mechanical factors concerned in the activity of the large bowel. Cannon's work on physiology of the gastrointestinal tract was of the greatest importance. One must recognize the various changes in the disposition of the colon content by antiperistalsis and the different kinds of onward peristalsis, especially the large mass of peristaltic movements which constituted the principal onward propulsive influence in the colon. The filling defect in the colon shadow due to carcinoma might be closely simulated by the irregular disposition of the colon content following one of these mass peristaltic movements. Filling defects due to the pressure of extracolonic tumors were often definitely indicative of the identity of the organ or tumor which made the pressure. Retroperitoneal sarcomata, uterine and ovarian tumors, splenic, hepatic and renal tumors were all likely to produce characteristic dislocations of the colon. Exaggerated antiperistalsis might be associated with either functional or organic obstruction in the distal colon. This tended to keep the bowel content as near as possible to the cecum. Hence it was not safe to judge as to the exact localization of the colonic obstruction from the point reached by the head of the bismuth colon. A combination examination by means of the colon injection and the bismuth meal gave accurate information as to the location of colon obstructions. Adhesions of the pelvic colon and other benign obstructing lesions were especially common below the crest of the left ileum. The cause of the obstruction might be functional, as in very marked spasticity due to colitis, or to spasticity of neuromuscular origin, or organic due to adhesions which were especially common in the distal colon. It was sometimes extremely difficult to differentiate between the roentgen findings in carcinoma of the pelvic colon and in adhesions of the pelvic colon, especially in women. The writer showed a number of cases of multiple diverticula of the colon, the diverticula varying in number from two or three to more than could be counted accurately. These diverticula were best seen after a bismuth enema, the bismuth meal having been administered fifty or seventy-five hours previously.

Bone Transplants.—Drs. ISIDORE COHN and GUSTAV MANN of New Orleans stated that their work was based on eighty-seven animal experiments. Gross sections were presented in which transplants had been placed in muscle, and not in contact with bone, for periods varying between forty-five and sixty-seven days. The transplants remained in all instances. Periosteal transplants had been placed as bands around the carotid artery forty-five to seventy-seven days. Subperiosteal resection of ribs and similar experiments failed to show any osteogenetic function on the part of the periosteum. The defect following the removal of a trephine button from the shaft of the tibia had healed as well when the shaft of bone had previously had periosteum removed as on the side on which the periosteum was allowed to remain. Intramedullary transplants remained and seemed to have taken part in the new bone formation. Histological preparations were being made of all specimens. The authors concluded that the periosteum was not an essential part of the transplant. When the transplant received sufficient blood supply it would grow. The bone transplant method seemed to be the ideal fixation for old fractures.

Relation of the Gastrointestinal Tract to Joint Disturbances and the Value of Eliminative Treatment.—Dr. WILLIAM A. MOWRY of French Lick, Ind., pointed out that derangements of the gastrointestinal tract operated in the production of chronic affections, such as rheumatism, gout, obesity, and probably diabetes. He had classified joint affections, excepting those purely traumatic, into infectious or toxic arthritis, true gout and autotoxemic arthritis. In the first group were those in which definite foci could be determined or strongly suspected, for which surgery and vaccines were the best recognized methods of cure. From a series of 244 patients suffering from joint disturbance, 92 were excluded in the consideration of the relation of the gastrointestinal tract to such cases. The remaining 152 cases were divided into two groups, 59 true gout and 93 autotoxemic arthritis, both terms often covered by gouty or lithemic. The principal points in the diagnosis of true gout were family history, eating and drinking habits, sex, (gout occurring oftener in the male than in the female), the clinical history of acute metatarsophalangeal joints attacking usually the great toe, cardiovascular changes, tophaceous deposits, abnormally low uric acid excretion, except during acute attacks. Gastrointestinal disturbances were common to both groups, and in the second group they had seemed to be important causative factors in the arthritis. The diagnosis of acute toxemic arthritis had been governed in these 93 cases first by the arthritis itself. Most of the cases were of chronic type. The fingers in these were affected equally in two-thirds of the cases, with toes, wrists, ankles, and elbows next in order of frequency. Constipation was very frequent in these cases, a few had diarrhea, while some complained of alternating constipation and diarrhea. Only one-third gave a history of headache, usually coincident with stomach or bowel attacks. In 48 per cent. of cases mucus was present in the stools, constantly or intermittently. Fully half of the patients complained of some form of indigestion most frequently with eructation and regurgitations. Examination in most cases confirmed the diagnosis of gastritis, colitis, chronic appendicitis, and probably cholecystitis. The urinary findings showed an average specific gravity above 1,025 with high acidity. Nearly all had a large amount of indican, no albumin or sugar in any, and traces of bile in but five cases. There were a few showing bile in the casts; large numbers of calcium oxalate crystals, in all but eight, and an excess of uric acid in over one-half. Blood pressure showed an average of 149 systolic, which was high for the average age—47. In the diagnosis of acute arthritis based in two cases on loose putrefying stools and in one on impacted fecal masses in the colon, immediate relief was given by internal irrigation, free purgation, and diet. Salicylates were used in the autotoxemic group and atophan in the gouty condition for the relief from pain, while fomentations and other hydrotherapeutic measures were regulated for each individual patient. Laxative waters were used for free elimination in all but two cases. Paraffin oil and castor oil were given when too large doses of a saline irritated the gastrointestinal tracts. The results of treatment were most gratifying. Seventeen patients were relieved entirely from pain or stiffness in the joints; all but fifteen of the remaining showed marked improvement. Patients were instructed as to the importance of diet and regulation of the bowels to insure permanent benefit.

The Conservative Versus Radical Treatment of Eclampsia.—Dr. J. HENRY CARSTENS of Detroit, Mich., drew the followng conclusions: (1) Pregnant women should have their blood pressure taken frequently and also have the urine examined. (2) If symptoms of toxemia developed, a most restrictive diet should be started and the woman placed in a position where she could have prompt medical attendance, preferably a hospital. (3) If convulsions occurred, premature delivery should be brought about by slow process, if the case was mild. (4) In severe attacks or convulsions, immediate delivery should be instituted by the so-called vaginal cesarean section, if the woman was about seven months pregnant or thereabout. If the woman was at full term, and especially in a primipara, an abdominal cesarean section should be the operation.

Salvarsanized Serum in the Treatment of Locomotor Ataxia, Paresis, and Cerebrospinal Syphilis.—Dr. WILLIAM LITTERER of Nashville, Tenn., drew the following conclusions: (1) The success of the treatment, other things being equal, depended upon early insti-

tution and the amount of nerve degeneration. (2) The number of treatments to be given depended partly on the condition of the patient, but more especially in using as an index the four tests which were generally known as (*a*) the Wassermann reaction with the blood; (*b*) the Wassermann reaction with the spinal fluid; (*c*) the cell count in the spinal fluid, and (*d*) the protein (globulin and albumin) estimations of the spinal fluid. (3) After giving 90 intraspinal injections of neosalvarsanized serum to 15 patients over a period of ten months, he had seen in some of those cases remarkable improvement which had persisted up to the present time. He believed the method in careful hands, with perfect aseptic and cautious doses, to be devoid of little or no danger. (4) On account of the numerous areas of poor vascularization in the brain and cord, the most rational contribution to the treatment of nervous syphilis appeared to be the intraspinal administration of salvarsanized serum. Whether it would entirely annihilate the spirochete or whether there might still remain inaccessible foci of infection, which would make recrudescence possible after the lapse of time, the future alone would determine.

The Value of Blood Pressure Readings in Examinations for Life Insurance.—Dr. J. W. FISHER of Milwaukee, Wis., drew the following conclusions: "(1) A systolic blood pressure reading should be required in all examinations for life insurance irrespective of the age of the applicant or the amount of insurance applied for. (2) A persistent systolic pressure of 15 mm. above the average for any given age should at least excite suspicion and call for further careful study and painstaking investigation. (3) Applicants of all ages with a persistent pressure above 150 mm. show a mortality higher than normal. The mortality increases as the pressure increases and also becomes greater progressively with the time of exposure. (4) The deaths of such applicants as had a high systolic pressure at the time of examination were caused, as might be expected, to a large extent by such diseases as apoplexy, arteriosclerosis, organic heart disease, and nephritis."

Weak Feet.—Dr. W. BARNETT OWEN of Louisville, Ky., drew the following conclusions: "(1) Weak foot occurs more frequently in females than in males, and in the majority of instances is caused by the wearing of improper shoes. (2) The most reliable diagnostic symptom is pain when standing or walking, which is relieved by rest. (3) As a prophylactic measure, normal individuals should be taught to walk with the feet parallel. (4) Abducted feet should be forced to acquire a normal attitude by a fulcrum at the calcaneoastragaloid joint. (5) All weak feet are amenable to treatment by mechanical or operative measures and proper exercise with application of appropriate shoes. (6) All mechanical support should be withdrawn as soon as muscular power has been sufficiently developed.

The Mortality and Morbidity of Appendicitis.—Dr. F. F. LAWRENCE of Columbus, Ohio, summarized his paper as follows: The mortality could be said to be determined by (1) The promptness of action after a correct diagnosis. (2) The period at which a correct diagnosis was made. (3) The patient, his resistance, his environment, and whether it was his first or one of many attacks. (4) The family doctor, his ability, his conscience, and his courage. (5) The surgeon, his judgment, his skill, and his personal attention to detail. The morbidity depended upon: (1) Delayed operations resulting in complications. (2) Abscess formation requiring prolonged drainage. (3) Inefficient drainage when drainage was required. (4) Incomplete operations. (5) Faulty technic which tends to irritate the peritoneal covering, strictures favoring adhesions, leaving the uncovered stump, disseminating infection by overlooking the physics of distension or of tension, and unnecessary trauma. In the ultimate analysis it all came back to the surgeon, his knowledge of anatomy, pathology, and his conception of his part in the care of this most complex condition.

The Present-Day Conception of the Treatment of Nephritis.—Dr. ARTHUR R. ELLIOTT of Chicago stated that advances during recent years in the therapy of nephritis had not been notable. The brilliant work of experimental pathologists in the production of the study of nephritis in animals had helped us a little in the treatment of the disease. Improvements in treatment might be summarized as a better handling of the cardiac problem, a better standard of control in diet, and improved prophylaxis. The most productive field of etiologic investigation today was the influence of chronic focal and confined infection in the causation of systemic disease. That this factor might play an important part in the etiology of chronic nephritis not only appeared probable, but it was strongly suggested by experience as the search for infective foci became more thorough. As a primary measure of treatment every case should be thoroughly examined for infective foci and these obliterated by radical treatment when found. Syphilis and chronic lead intoxication were other insidious factors that should be combated. In chronic nephritis many of the old qualitative restrictions had been done away with. Recent observations apparently showed that in the vast majority of cases during the stage of cardia compensation that total function of the kidneys was well up to normal as shown by the phthalein test and the ratio of nonprotein nitrogen in the blood. Aided by periodic functional testing to check up the kidney condition the diet might be so regulated as to maintain general nutrition and kidney conservation on a parity. He discussed the items of fluid restriction and salt-restriction advocating the performance of fluid and salt excretion tests in every case of chronic nephritis before laying down the diet. If one wished to gather all possible clinical data he would not rest satisfied with the diagnosis of nephritis, but would proceed to determine for prognostic and therapeutic purposes the degree to which the functional impairment of the kidneys had advanced. This could be done by means of the functional tests, and the best and simplest test for total function was the phenolsulphonephthalein test of Rowntree and Geraghty. This might be used with advantage in the study of any case applying to the test at intervals in order to keep track of the functional index, thereby affording help toward regulating diet and instituting eliminative measures. The most important item in the treatment of chronic nephritis was the preservation of cardiac compensation. The high blood pressure and cardiac hypertrophy of chronic nephritis constituted a compensatory mechanism enabling the kidneys to maintain adequate function. They consequently were essential to the preservation of life and should be protected by every hygienic and dietetic safeguard. High blood pressure should not be made the object of direct therapeutic attack. Nitrites should be reserved for emergency use to combat such developments as angina, cardiac asthma, etc. The appearance of dropsy in primary chronic nephritis almost invariably signified the advent of cardiac failure. At this stage the digitalis bodies became the mainstay of treatment and should not be withheld because the blood pressure was high, as they acted just as well or even better with a high blood pressure as with a falling pressure.

The Pathology of Syphilis of the Heart.—Dr. ALDRED SCOTT WARTHIN of Ann Arbor, Mich., stated that the pathology of syphilis of the heart, as given in the majority of the text books on pathology and medicine, was about fifty years old, based upon observations made by the generation of pathologists who worked under the influence of Virchow. Even the best text books on special pathology at the present day (Kaufmann's and Aschoff's) gave little attention to cardiac pathology from this disease and added nothing new. Observations made by the writer based upon the presence of the spirochete in the myocardium had greatly extended our conceptions of cardiac syphilis and its clinical significance. Cardiac syphilis must at the present time be reviewed from a broader standpoint of acute parenchymatous and interstitial lesions due to the presence of the spirochetes in the myocardium rather than from the more restricted standpoint of gumma, arteriosclerosis, and fibroid heart. The writer had shown that purely parenchymatous lesion, such as cloudy swelling, fatty degeneration, hydropic degeneration, atrophy, and coagulation necrosis, might be the result of a localization of spirochetes in the heart muscle, and that such parenchymatous lesions might exist in the entire absence of any interstitial changes. As the result of such purely parenchymatous lesions, cardiac hypertrophy and dilatation might be produced as well as serious disturbances of the heart's action and efficiency. In fatal cases of cardiac insufficiency and dilatation, the only myocardial lesions present might be purely parenchymatous. That such lesions were syphilitic was shown by the presence of spirochetes in the muscles of such hearts. Between such parenchymatous lesions and the condition of ultimate fibrosis there existed every possible stage of gradation. The parenchymatous changes at times were accompanied by interstitial edema, cellular infiltrations and cell proliferation. In a great majority of cases these acute

interstitial changes were of slight degree and could not be recognized by the naked eye upon inspection of the heart. The separation of the muscle fibers in such cases was often due to a fluid containing mucin, a peculiar form of myxedema which was especially common in congenital syphilis. With an increase in the number and virulence of the spirochetes, the interstitial changes might become more marked and the picture of a localized or diffuse interstitial myocarditis was produced. These interstitial changes were particularly prominent in the neighborhood of the smaller branches of the coronary vessels, often partaking of the nature of a periarteritis or a periphlebitis. Spirochetes could always be found in these interstitial lesions until the connective tissue proliferation became scarlike or hyalin. Such fibroid areas rarely contained the spirochete. But wherever there were cellular portions or a connective tissue that was edematous in character, typical spirochetes could be found by the Levaditi method. The fibroid areas were therefore to be looked upon as the result of local healed processes. In the writer's experience, autopsy findings showed the presence of such syphilitic scars in the heart of every syphilitic, whether the disease be active in some part of the body or cured. In association with these scars in some part of the heart, on serial section the writer had always found active areas that contained spirochetes. He regarded the parenchymatous and interstitial lesions as the most important result of syphlitic infection of the heart. In his experience he had found the gumma to be very rare, having met it but once in acquired syphilis, but much more frequently in congenital syphilis in the form of a myxogumma. As sequelæ to these parenchymatous and interstitial changes, he found the fibroid heart as the ultimate condition. Associated with this there might be coronary sclerosis and thrombosis, anemic infection, localized endocarditis, or pericarditis, cardiac thrombosis, cardiac aneurysm, dilatation or heart rupture. The clinical symptoms varied from the mildest grades of cardiac insufficiency to the most severe. Angina pectoris was frequently present in the fibroid stages, and in a large number of cases there were marked disturbances of rhythm. Cardiac thrombosis frequently led to sudden death. The important clinical lesson to be derived from this was that syphilis, especially latent or cured syphilis, was the most important etiologic factor in heart disease and that our conceptions of syphilis therapy must be extended to periods of treatment over many years, if not through the entire life of the patient, rather than for a restricted term of two, three, or even five years.

The Emotional Factor in the Psychoneuroses.—Dr. Louis Miller of Toledo, Ohio, stated that in analyzing cases one would find the mental preoccupation to have followed along certain special lines. In one person it might be in regard to his health, in another it concerned the affections, and in another sexual matters. In the first place, by persuasion one endeavored to re-educate the patient to think clearly in a matter-of-fact way, to orient himself, to see the true relationship of facts. Second, an effort was made to patch together the disintegrated personality. Third, the affective state was influenced for the better by reassurances of a cure, by the patient's confession, liberating him to an extent from the effects of possible remorse and self-reproach, by redirecting him to definite aims in affairs and ambitions, and by comforting him. On the whole, this method had given the author better results than any other. If the cure succeeded, there was less chance of relapse than with methods like simple suggestion, or the use of electricity, drugs, etc.

Gall-Bladder Infections: Their Treatment from a Surgical Point of View.—Dr. Louis Frank of Louisville stated that his own operative work in recent years, particularly during the last two and a half years, since he had familiarized himself with the anoci-association method, had been performed under gas-oxygen anesthesia and complete blocking, contenting himself with preliminary drainage of the gall-bladder, and dividing the operation into two stages. After the gall-bladder had been permitted to drain for some time, and the patient's temperature had receded to normal and the jaundice had subsided, he then did a secondary operation for the purpose of removing the obstruction from the duct. In other words, he treated these cases by a two stage operation just as he did the old prostatic with high blood tension and impaired kidneys and a septic bladder. He was sure that the mortality had been materially reduced, and he would offer this suggestion to those who had not yet tried the method.

The Medico-Legal Aspect of Radiograms in Diagnosis and Treatment of Fractures and Joint Injuries.—Drs. John D. Trawick and D. Y. Keith of Louisville said that whether for judge, or jury, or lawyer, the photograph of a bone or joint lesion was evidence of an actual condition, and only the expert was capable of drawing conclusions as to the meaning of such condition and to interpret the probable effect of such lesion upon the possessor. Before the jury a radiogram was purely secondary evidence, a mere representation of a condition existing, and from that radiogram alone no judge could draw conclusions as to the probable results or ultimate function.

Shortening of the Round Ligaments by Transverse Suprapubic Incision.—Dr. Sigmar Stark of Cincinnati stated that should the examining fingers which had been introduced into the abdomen detect the existence of serious adhesions, tuboovarian disease, or other complications, then the procedure was as follows: The lower ends of the external oblique incisions were joined by a transverse fascial incision and the abdomen opened in conformity with the procedure of Pfannenstiel. Disturbances within the pelvis were eliminated and the abdomen closed according to the method peculiar to the Pfannenstiel incision. The round ligaments were then attached to the fascia in the manner previously described. Three of the cases in his series belonged to the complicated class, having been associated with pyosalpinx, ovarian abscess and extensive adhesions. It was particularly in this class of cases that the value of this procedure became evident as it enabled one to cope readily with complications very difficult to overcome with the bi-inguinal incision. Additional advantages were to be found in the greater ease with which the round ligaments were exposed, the greater rapidity with which the operation could be performed, the employment of a single incision, and the fact that the best part of it was hidden by the pubic hair.

THE MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Stated Meeting, Held October 26, 1914.

The President, Dr. T. Passmore Berens, in the Chair.

Unilateral Hematogenous Infection of the Kidney.—Dr. John H. Cunningham, Jr., of Boston, read this paper by invitation. He referred to acute unilateral infection of the kidney as a relatively rare, but interesting, and extremely important disease, and said that their knowledge of it was due largely to the communication of Dr. George Brewer, published in 1910-1911, recording cases and his experimental work. The acute renal infections of hematogenous origin were of two distinct classes: one induced by infective or toxemic conditions, for example, nearly all of the infections which gave rise to general diseases such as diphtheria, scarlet fever, measles, pneumonia, typhoid fever, etc. The disturbance within the kidney was due, in this class, to the action of toxic substances elaborated by the virus of the special disease which was in part eliminated through the kidneys. While the toxic substances of these acute general diseases conveyed to the kidney by the blood stream induced cellular necrosis, it was rare that suppuration occurred, and this type of hematogenous kidney remained medical rather than surgical. It was the second, rather smaller, yet more serious, class of kidney infection of hematogenous origin, whereby the kidney was invaded by the microorganisms themselves, resulting in acute inflammation and suppuration, that commanded attention from a surgical standpoint. Infection of this kind was theoretically of a metastatic nature, and when encountered in both kidneys was usually consecutive to septic endocarditis or other septic affections elsewhere in the body. When it occurred in but one of the two kidneys, the primary focus from which the organisms found their way to the kidney had seldom been determined. The pathology of acute unilateral hematogenous infections of the kidneys was quite different from the acute bilateral kidney infections. The latter were an expression of general septicemia in which the kidney participated while the former were not a part of general pyemia, but found their origin in the lodging of a minute embolus carrying one or several organisms in the terminal vessels of the kidney. It was believed that the process might be started by a single microorganism. The condition

started as a single focus in the cortex of the organ, from which other areas were secondarily involved by the infectious material gaining access to other tubules, to the lymph spaces, and through the vessels in the connective tissue stroma. This pathological process was of two distinct types: (1) Abscess formation, and (2) a diffuse inflammatory process without breaking down of the tissue. The organisms producing the first type were the pyogenic cocci. The second type of the disease had the same sequence of events in its pathology when of hematogenous origin. The clinical course of these two forms of the disease differed in some respects, and each had a definite relation with these two different pathological conditions. The picture which unilateral multiple abscess formation produced was an acute disease which might or might not be ushered in by a chill. There was a rapid rise of temperature to from 102° to 105° F., and an early acceleration of the pulse rate, usually to 120 or higher, occurring often within twenty-four hours of the onset. A high leucocytosis developed rapidly. Pain on the side of the diseased organ, abdominal tenderness, muscular rigidity, and spasm were found on the affected side. Lumbar tenderness, rigidity, and spasm were pathognomonic signs of the disease. The abdominal signs were similar to those occurring in acute affections of the appendix and gall-bladder, for which these diseases of the kidney were often, if not usually, mistaken. The diagnostician when confronted with a problem in the right upper quadrant of the abdomen must include acute infection of the kidney as a possibility. The urine in this disease did not excite suspicion of the true condition. When the infection was severe the patient grew progressively and rapidly worse, the toxemia became profound, delirium set in, and there was a fatal termination within a few days unless the body was rid of the infected organ. The clinical picture produced by a diffuse inflammatory process within the kidney without abscess formation differed from that with abscess formation chiefly in the severity of the symptoms and was the type of the disease most usually due to *B. coli* infection and most difficult to distinguish from an ascending infection. The chief feature differentiating this form of disease from that of abscess formation was the lesser degree of progressive toxemia and the presence of more abnormal elements in the urine. The illness after the first few days following the onset remained more or less stationary and might continue not unlike a beginning typhoid fever. Remissions in the acute symptoms occurred, but indefinite pain on the affected side usually persisted. Dr. Cunningham cited cases illustrating both of these types of disease and concluded that in the first class, the kidney with multiple miliary abscess formation from which malignant toxemia resulted, the organ must be sacrificed in order to save the patient's life. In one of the cases reported only the central quarter of the kidney was involved. In this instance the infected area was removed by a resection of the middle third of the kidney and the healthy upper and lower thirds united successfully and the outcome of the case was most favorable. This procedure, however, must be considered hazardous and could not be recommended. In the other cases of this class nephrectomy was performed and it was felt that this offered the only hope of saving the patient's life. The proper treatment in the second class, the type of diffuse acute unilateral inflammation of the kidney, could not be so clearly defined and must depend on the course of the disease in the individual case. As a broad rule, it was felt that palliation, forcing fluids, and the employment of urinary antiseptics, fortifying the patient's health by a nutritious diet and stimulating drugs, should be instituted at the outset, and operative interference should only be undertaken when the symptoms and physical signs gave evidence of progression to the point of serious lowering of the general resistance by toxic absorption. The time to operate in this class of cases required experience with the disease and judgment in regard to the patient's general condition. Some of the patients recovered without operation as noted by Brewer, Cobb, and others, and in the seven cases mentioned in this communication. When an operation was undertaken in this class of cases nephrectomy was not the only procedure to be employed. Favorable results had been obtained by simple decapsulation, by puncture of the infected area with drainage, and by splitting the kidney, closing the kidney wound by suture and decapsulating the organ, or decapsulation and drainage of the kidney pelvis. When the symptoms and signs were of a distressing nature and the infected kidney was found to be the seat of an old as well as a new inflammatory process, or when the acute process was extensive, nephrectomy was the best procedure. When the infecting organism could be isolated, vaccine therapy might be of value.

Dr. George Emerson Brewer expressed his pleasure at listening to the paper because it was one that had not been generally discussed; this type of disease had not been recognized as it should have been. He was pleased to learn that Dr. Cunningham had come to practically the same conclusions as he had in his clinical observations. His presentation of the subject was most complete, and especially his classification. He had also arrived at the same conclusions, but Dr. Brewer had not studied his cases as carefully. Dr. Cunningham spoke of the toxic type of the infection of the kidneys such as followed scarlet fever, diphtheria, and other acute infectious diseases. These were the results of toxemia, but not in all cases. Dr. Brewer then reported what he termed a typical case of scarletinal nephritis in which a nephrectomy was done. He next considered two types of cases which were to be differentiated by the symptoms alone. There was the severe type with the chill and high initial temperature of 104° or 105° F., in which in a few hours there would occur the distended abdomen, pain, and signs of an intraabdominal affection. There had been six cases in Roosevelt Hospital during the past eighteen months and in five the diagnosis had been "acute appendicitis." It had been strongly impressed upon him that in the great majority of the cases presenting clinical histories and physical signs strongly suggestive of some abdominal lesion, they got signs of renal disease. It seemed to him that the progressive toxemia differentiated these cases. It was timely and now necessary to recognize them. These cases of the mild type could be treated expectantly. Dr. Brewer referred to many cases that arose as the result of unilateral hematogenous infection of the kidney. The renal infection through the blood current was more common than the ascending infections. The examination of the urine showed little to lead one to suspect any kidney infection. The urine was as clear as cherry wine; but when it was centrifuged there would be found a few red blood cells, a few white cells, and a trace of albumin. The kidney was the seat of infection and was practically functionless. Dr. Brewer said that he had tried to produce experimentally a typical pyelitis in animals, but had never been able to succeed. They were all acute hematogenous infections.

Dr. Fenton B. Turck said that the old question in these cases of unilateral, as well as bilateral kidney infection was, whether the microorganisms were carried by the blood stream or through the tissues by diffusion, as commonly occurs from the gastrointestinal tract. Experimental evidence seemed to indicate that hematogenous kidney infection was of rare occurrence. In 1896 Biedel and Kraus injected *Pyococcus aureus* and *B. coli* into the blood and recovered them in the urine in 13 to 25 minutes. The urine remained albumin and blood free. Futterer and others, even after traumatism and various devices, had failed to produce hematogenous infection of the kidneys. N. P. Marsh claimed that infection was rarely carried by the blood, but ascended by the way of the ureter, or descended with the passage of germs from the bowel to the kidney. Hess regarded ascending infection as the usual form and Scheidemandel showed that infection through the lymphatics had an anatomical basis from the cecum and ascending colon to the right kidney. L. Fejes, as well as Muller, has also shown that the invasion of the kidney occurred *via* lymph spaces in the walls of the bladder and ureter. In Turck's own experiments repeated intravenous injection with *B. coli* or pyococci produced no marked acute or chronic kidney lesions. When the microorganisms were fed daily to dogs, kidney lesions invariably occurred, but the blood always remained sterile. The microorganisms through osmosis passed between the epithelial cells lining the intestines into the areolar tissue of the submucosa, and in the same manner proceeded onward between the muscle coat and the mucous membrane. From here the diffusion took place rapidly. The precise route of the microorganisms injected into the lower bowel was studied in the fetal pig. The fetal animal was sterile and while the circulation was stopped the tissue cells were living and the *vitro-vivo* experiments indicated a similar diffusion route, as that which occurred in the adult animal. It

was not necessary to starve the animal in order to cause the microorganisms to migrate from the intestinal lumen, as Ficker thought, or to introduce very virulent strains into the intestines, as had been suggested by Hedgerman. Dr. Turck had found that congestion of the abdominal vessels, as in case of shock or by tying off the mesenteric vessels to interfere with the blood supply, would cause the microorganisms to pass between the cells as through the pores of a filter, not entering the blood stream, but moving on by the interstitial route. Infection of kidney with *B. coli* occurred alone or in symbiosis with the pyogenic cocci. The *B. coli* might undergo rapid bacteriolysis and disappear, leaving conditions favorable for the growth and more destructive effect of the pyogenic cocci. The unilateral infection of the kidney would indicate the tissue diffusion route rather than the hematogenous, as shown by Hess, Marsh, Bond and others. The path taken by the microorganisms from the intestines to the kidney passed between mucous membrane and the muscle coat, reaching the bladder by the lymphatics, then up the bladder wall and ureters to the periphery of the kidney, continuing along the interstitial zone under the capsule and there set up the infection, as so beautifully shown in the lantern slides presented. A careful study of the precise nature of the etiology of these kidney infections was highly essential, as operative interference, according to Scheidemandel and others, was reserved for only undoubted abscess formation, and in any event the source of the infection must be stopped. The apparently sound kidney also needed protection. He had previously referred to the importance of intestinal treatment including the atony and splanchnic congestion combated by colonic lavage with colloidal demulcents, special diet, ingestion of hemicellulose demulcents, such as Irish moss, slippery elm emulsion, combined with liquid vaseline, which together acted as an artificial mucus, a barrier against the passage of bacteria through the intestinal wall. Alkalies, collodial metals, internally, and autogenous vaccines planted within the pelvis of the kidney supplied some of the indications for general and local treatment.

Dr. Edwin Beer said that although he had not had the pleasure of reading Dr. Turck's paper, in which he said he proved that the kidney infections followed the tubular channels from the bladder up through the ureter, and threw doubt on the paths of infection just described by Dr. Brewer, he felt that it was the duty of any one who had experimented along these lines to challenge the statements of the last speaker. Having done considerable work along these lines he could confirm much that Dr. Brewer had said. Mildly virulent germs introduced into the circulation would be deposited in traumatized kidneys, and lead to multiple abscesses without infecting the pelvis, *i.e.* without there being any pyelitis, as the last speaker would have them believe. On the other hand, virulent germs killed the experimental animal before the multiple abscesses formed, apparently from sepsis.

Question for Discussion: The Status of the Specialist in the Field of Surgery.—Dr. Charles H. Chetwood introduced the speakers as follows:

Ladies and Gentlemen; Doctors, Physicians, Specialists and Surgeons—Especially General Surgeons: Several months ago, the President of the County Medical Society paid me the honor of requesting me to arrange the program of the present meeting. And now, having listened to what has gone before, under the inspiration of our eminent guest from Boston, and in anticipation of what is yet to come, from the all-star cast that the remainder of the program announces, I am enjoying some of the feelings of a successful impressario.

My own part in the program is a brief one. It is to propound the question of the hour, which is to define the status of the specialist in the field of Surgery, and which, if I read aright the temper of the times, is agitating the minds of all of those who are concerned in the result of the verdict, be they Urologists, Gynecologists, Ophthalmologists, Otologists, Pediatrists, Rhinologists, and many others, too numerous to mention. Against this army of—shall we say invaders, these Allies?—there stands alone the Kaiser in the person of the General Surgeon. The General Surgeon wants to know where he "gets on," because the specialist doesn't know where to "get off."

Like all questions, great or small, this one has two sides to it, and one side seems to have been characterized in song. In the Lay of Koko, of Mikado fame, we have the General Surgeon's refrain, which runs somewhat in this vein:

As some day it may happen, a clearance must be made,
I've got a little list, I've got a little list
Of medical offenders, who should all be in the raid,
And who never will be missed, who never will be missed.

Query: Is the General Surgeon being driven from the field of operations upon any portion of the human anatomy, save that, perhaps, which already belongs to the tonsorial specialist? Or, on the other hand, shall the Urologist, the Gynecologist, and others of selective fame, expend their efforts in all that may tend toward the illumination of a case in question, and then, the moment operation becomes a consideration, shall recourse be had to a "real surgeon" or "operating specialist"?

To be sure, this question has its rules and its exceptions. It may depend upon whether it be applied to hospital or private practice. In my own case, I maintain there is a decided exception, and, as you no doubt have discovered, I am unable to discuss this subject seriously. I turn to these gentlemen, who are waiting in the lists, eager for the combat! You, Urologist, and You, Gynecologist, and You, any kind of "Ologist"! who doubt the General Surgeon's superior skill, and when 'tis said:

"To operate or not to operate
That is the question"* * *

You answer:

"To sleep, perhaps to die,
And there's the rub!"

But still the General Surgeon chants, with irritating grace:

There's the medico who plays upon the weakness of his race,
The G. U. Organist, I've got him on the list, I've got him on the list
He's just the same, tho' changed in name, as the Urologist;
He never will be missed, he never will be missed.
And last of all tho' not the least—in numbers they can boast,
For operations, great and small, they surely do the most,
That medical anomaly, the Gynecologist
He never will be missed, I'm sure he'll not be missed.

Province of the Urologist and Gynecologist in the Domain of Surgery.—Dr. Edwin B. Cragin said that some had argued that the province of the specialist was diagnosis and prognosis, and that the general surgeon should do the rest. Yet when one saw a general surgeon of the highest type specializing on diseases of the brain and spinal cord he could not but feel that a specialist was justified in cutting if he could do it better than his colleagues. The relation between gynecology and general surgery might perhaps be best represented by a concrete example. Other things being equal, the general surgeon would do better stomach work than the gynecologist because he did more of it and was more interested in it. For the same reasons, other things being equal, the gynecologist would excel in diagnosis, operative judgment, and surgical technique in any female pelvic work. Regarding the relation between urology and gynecology it might be said that the urologist from more frequent practice would usually be more dextrous in the use of the cystoscope and the ureteral catheter than the gynecologist, and yet it was absolutely necessary that the gynecologist, in order to hold his position in Class A of this specialty, be able to do this work. There was a border land in both urology and gynecology where cases were bound to overlap as, for instance, a cystic kidney resembling an ovarian cyst, or *vice versa*, and speaking for the gynecologist, he must be able to deal with this condition. Something should be said regarding the relation between gynecology and obstetrics. A man might be a good gynecologist without doing obstetrics, although he believed he was a better gynecologist if he had an obstetric service in which he could observe the effect of his operations on the process of maternity. On the other hand, one could not be an obstetrician in Class A to-day unless he was a gynecologist. The obstetrician of to-day and the future must be able to deal with cases of ruptured ectopic gestation, of ruptured uterus, and of pregnancy complicated by a tumor with twisted pedicle. He must be able to perform cesarean sections whether they were to be completed according to the orthodox Saenger method, or were to have added to them a myomectomy or a hysterectomy. In other words, the obstetrician must be able to do all kinds of

female pelvic work. This at present was called gynecology. In closing he wished to say a word regarding the preparation of the gynecologist. The preparation of experience with the speculum, the glycerin tampon, and the iodine swab would no longer hold as a requisite training for the gynecologist. He must have a surgical training and must be able to do the highest type of surgery in the pelvic field. Just so long as the gynecologist in diagnosis, surgical judgment, and operative technique could excel the general surgeon in female pelvic work, he deserved to hold his position and would do so. Failing to excel the general surgeon in this particular field, he deserved to be superseded.

The Relation of Gynecology and Urology to General Surgery.—Dr. HOWARD LILIENTHAL read this paper. (See page 872.)

Dr. EDWIN BEER said that the question under discussion as he saw it was, who should do the surgery of the kidneys, ureters, and bladders? Urologists claimed it as their field and general surgeons and gynecologists liked to make excursions in that direction. It was not his belief that they would settle the question, but it was a live one and deserved earnest consideration. This was an era of specialization and it had become such because the specialist did better work than that surgeon who devoted his major energies to other fields. In his opinion the answer to the question before them would be found in a consideration of the training that a physician should have, if he wished to do the surgical work on kidneys, ureters, and bladders. Such a physician should be an expert cystoscopist in the broadest sense, able to understand the pathological pictures, able to operate through the cystoscope, able to avail himself whenever the indication arose during an examination of the many resources that made for successful results, which only careful study, reading, and, above all, practice, developed. He should have a thorough knowledge of laboratory cooperation, bacteriological, chemical, and *x*-ray, and should constantly make use of these aids. In addition to these fundamental acquisitions he should be trained in general surgical technique so that he could meet all surgical emergencies and give his patients the best available care. The surgery of the organs under discussion was most difficult major surgery and it was absolutely wrong to think that anyone who handled the scalpel could do it efficiently. Any physician who fulfilled the requirements outlined was, in the speaker's opinion, fitted to apply surgical remedial methods to diseases of the kidneys, ureters and bladder.

The Province of the Gynecologist in the Domain of Surgery with Special Reference to the Malposed Kidney.—Dr. DOUGAL BISSELL presented this paper which was read by Dr. Charles Gardner Child, Jr. He said that he was free to admit at the outset that the line of demarkation between the surgical work of the gynecologist and that of the general surgeon was at times difficult to draw, but the same was true when discussing the limits of any branch of surgery which dealt with more than a very limited number of organs. Again it was difficult to draw a line between two recognized divisions of a special department of surgery, as for instance, gynecological and obstetrical surgery. In reality gynecological and obstetrical surgery went hand in hand and were practically inseparable, and a gynecologist without a thorough training in as well as a practical knowledge of obstetrics could lay claim to only a limited knowledge of diseases peculiar to women. They should be emancipated from the generally accepted limited meaning of the term "gynecology," claiming the same right to include the urinary system in their specialty as was conceded to those surgeons who dealt exclusively with diseases of the male. The writer expressed himself as being further puzzled to understand why the term "genitourinary" should be applied only to the surgery of the male, and claimed that the same might with propriety be applied to surgery of the female. The anatomy of the female genital organs was such that they were of necessity often forced to encroach upon the domains of general surgery when correcting pelvic complications so commonly met with in inflammatory diseases of the female genital organs. The writer then proceeded to consider the importance of the malposed kidney from the gynecologist's standpoint. Renal malpositions had not received the attention they deserved, and it was the gynecologist's opportunity to discover and teach their importance as a large proportion of them occurred in the female. As pathological entities, their existence was questioned by many students of medicine, and, even when admitted, surgical procedures for their replacement were given scant consideration. Symptoms resulting in the female from renal displacements or misplacements were many and varied, and might be classified under several groups, but their interest at the present time was directed to those symptoms which led the female and even her physician to believe that some genital disarrangement or disease existed. Pain was frequently present, but to conclude that the prolapsed kidney unaccompanied by pain was a harmless abnormality was a mistake. Furthermore, when it existed it was misleading, especially when located in the cecal or ovarian region, and in many instances was the sole reason for the removal of an appendix or an ovary. Acute pain in the kidney region indicated either a recent displacement of the organ or a displacement of considerable duration with distention of the upper urinary tract, the result of imperfect drainage. Those that held that pain must be present as an active symptom before nephropexy was justified forgot that in other acute displacements pain existed and was usually severe at the beginning, often being mistaken for other pelvic or abdominal lesions, but subsequently disappeared, followed in the vast majority of instances by neurotic disturbances. The association of symptoms referable to the bladder and the genital organs of the female with malposition of the kidney was too common to be considered coincidental. With the genitourinary symptoms one usually found those referable to the digestive and nervous systems and not uncommonly the prolapse was marked and of long standing, and the resulting general condition of the female was worse than that which followed pelvic disorders. Prolapsed kidney and menstrual disorders were often related as cause and effect, and in his own experience he had seen convincing evidence in certain cases that these symptoms were removed completely by the fixation of the kidney. In certain cases in which he had succeeded in relieving symptoms by nephropexy only, curettage alone had been previously resorted to for the cure of excessive flow and with but temporary or no relief (Kindelong). In other cases curettage with repair of lacerations and even replacement of the uterus, and in still others removal of the appendix alone or with the ovary or ovaries, as well as the removal of fibroids and diseased adnexæ without relief, in which a prolapsed kidney had been ignored, were corrected by a recognition of this mistake. It was his opinion that they too frequently attempted to diagnose by subjective or objective symptoms alone, and as a result not only minor gynecological lesions were repaired, but also major operations performed while the offending lesion was overlooked. He was convinced that if these facts were more generally appreciated fewer appendectomies, divulsions, and curettages, and even hysterectomies, would be performed. Prolapse of the kidney and retrodisplacement of the uterus though frequently associated were independent in origin. As the group of symptoms accompanying each had many features in common, there was danger of the surgeon, when discovering one lesion, hastily to conclude that the entire cause of the disturbance had been found. A replacement of either of these organs alone usually met with a disappointing result, as the correction of all elements entering into the pathology of the case was necessary to the complete restoration of the patient's health. The development of a specialty means a concentration of intellectual energy and skill upon division of a great subject and the specialist was a necessity only so long as surgeons operating generally failed in part or in whole to grapple successfully with the problems at hand. The result of the specialist's efforts was a rapid development and standardizing of surgical operations and technique in a given field. When in all departments of surgery it was an accomplished fact and there existed no longer a question as to what operation or technique was best under a given condition, the day would then have arrived when, though specializing might continue, the specialist or pioneer, as we know him, having completed his usefulness, would disappear.

PHILADELPHIA NEUROLOGICAL SOCIETY.

AT a stated meeting held October 23 Dr. WILLIAM B. CADWALLADER presented "A Case of Facial Hemiatrophy Greatly Improved by the Administration of Thyroid Extract." The patient was a woman, about 24 years old, who had presented an area on the left cheek over which the skin was shiny and parchment-like, and the subjacent tissues were wasted. Under treatment with thyroid extract in doses of one and two grains

thrice daily the local condition improved gradually and progressively until the skin lost its glossy appearance and acquired a considerable degree of mobility.

Dr. H. MAXWELL LANGDON presented "A Case of Tabes with Hippus." The patient was a colored man, about 28 years old, with ataxic gait and station abolition of knee-jerks, bilateral optic atrophy, and unequal pupils, one of which manifested characteristic hippus on exposure to light.

Dr. CHARLES W. BURR presented "A Case of Multiple Neuritis, with Astasia-Abasia." The patient was a man, about 45 years old, who exhibited weakness in all four extremities, consequent upon which he developed great difficulty in standing and in walking. It was thought the early symptoms were due to the lesion of the nerves, while the later ones might be attributed to functional disorder of hysterical character.

Dr. JAMES HENDRIE LLOYD presented "A Case of Tabes Dorsalis Suggestive of Friedreich's Ataxia." The patient was a man, about 28 years old, who presented ataxic gait and station, absence of knee-jerks, insignificant ocular changes, and high foot-arches. There was no history of similar disease in the family and the Wassermann reaction was negative.

Dr. CHARLES K. MILLS presented "A Case of Probable Cerebellar Disease." The patient was a man, about 65 years old, who had a seizure followed by motor disorder on the left side of the body, as manifested by difficulty in standing and walking, with a tendency to fall backward or to the left. On douching the right ear with water the usual responses with respect to nystagmus and the coordination of the fingers were found wanting, while these were present when the opposite ear was similarly treated. Accordingly it was concluded that there was a lesion of the cerebellum on the right side in its anterior-superior portion.

Dr. ALFRED GORDON presented "A Case of Hemiplegia with Unusual Symptoms." The patient was a man, 24 years old, who at the age of 8 had had an attack of typhoid fever, at the height of which he had a convulsion followed by weakness of the left side of the body, in association with temporary aphasia. In the interval the affected parts had undergone no wasting or want of development, but the right upper extremity exhibited certain contractures in accordance with varying positions of the part and there were also a number of associated movements. Speech was soon fully recovered. The knee-jerks were exaggerated, but there was no ankle clonus and no toe-phenomenon. It was believed the symptoms were due to a lesion outside the internal capsule, perhaps in the lenticular nucleus, and that the condition might be designated extra-pyramidal hemiplegia.

Dr. DAVIDSON presented for Dr. Wm. G. Spiller "A Case of Bilateral Lenticular-Nucleus Lesion." The patient was a man, about 30 years old, who had had an attack attended with disorder of motility on the left side and later a second attack followed by similar disorder on the right side. At times, when not observed, the man was quite still, but often, and particularly when under observation, he presented a fixed smile and he made movements of the shoulders or of the feet. He was able to walk well, but in the performing of this act he at times also engaged in extraneous movements. Intelligence was fairly good. There was a history of multiple venereal infection and the Wassermann reaction was positive.

Drs. WM. DRAYTON and H. MAXWELL LANGDON presented "A Case of Tabes Dorsalis with Lost Tendon-Reflexes and Argyll-Robertson Pupils, but Without other Characteristic Symptoms." The patient was a man, 22 years old, who presented himself with neurasthenic symptoms, but in whom routine examination disclosed absence of knee-jerks, ankle-jerks, abdominal reflex, cremasteric reflex, with contracted pupils, reacting in accommodation but not to light. He could walk perfectly well and had no ataxia in the upper extremities. Sexual power was preserved and there was no history of syphilis. The blood yielded a negative Wassermann reaction, but the cerebrospinal fluid yielded a weakly positive Wassermann reaction and the number of lymphocytes was increased.

Dr. FRANCIS X. DERCUM presented "An Interesting Case of Brain-Tumor; Localization by Means of *X*-Ray." The patient was a man, about 30 years old, who had seven years before exhibited some twitching of one side of the face, but who had no disorder of motility, no headache, and no convulsions. There was some mental irritability and some loss of memory, and *x*-ray examination disclosed clearly a tumor in the midst of one cerebral hemisphere. There were slight fundus-changes in one eye. It was concluded that the neoplasm, situated in a silent area and giving rise to no symptoms, had undergone calcification and had better be left undisturbed. Dr. Willis F. Manges demonstrated the *x*-ray pictures.

Dr. TOM A. WILLIAMS reported "A Case with Lesions Around the Sella Turcica." The pathological changes were disclosed on *x*-ray examination, and improvement followed on treatment with *x*-rays.

Dr. CHARLES M. BYRNS presented a communication entitled "The Indradural Administration of Mercurialized Serum in the Treatment of Cerebrospinal Syphilis." It was reasoned that when salvarsan or even a mercurial salt was introduced into the cerebrospinal fluid or the blood only small and uncertain amounts could be looked for in the serum obtained from such an individual, whereas if a definite amount of a soluble mercurial salt, such as mercuric chlorid, were added directly to the serum obtained in the usual manner the dosage could be more accurately set up, and more nearly positive results looked for. Practical application of the method clinically confirmed the correctness of the reasoning, and in some instances better results were obtained by this method than from the employment of salvarsanized serum, notably in some cases of tabes and paresis.

Dr. WILLIAM G. SPILLER presented a communication entitled "Intense Jaundice in the Newborn Child as a Cause of Encephalic Arrest." He cited a number of instances of mental deficiency, with or without motor phenomena, in which intense jaundice had been present, and he raised the question whether the associated toxic or infective process might not in some way be responsible for the changes in the nervous system. It was suggested that the underlying hemolysis or the profound cholemia might exert a deleterious irritative or destructive influence upon the delicate nerve-structures, and in this way bring about the symptoms noted. This was not to be expected of the mild and ordinary forms of jaundice, but only of those of profound degree associated with pronounced hemolytic or toxic infective changes.

COLLEGE OF PHYSICIANS OF PHILADELPHIA.

AT a stated meeting held November 4 Dr. CHARLES A. ELSBERG of New York presented by invitation a communication entitled "Pain as a Symptom of Diseases of the Spinal Cord, and its Surgical Treatment," illustrated with lantern slides. He pointed out the relative frequency with which pain in one portion of the body or other is referred to disorder of nerves or of internal viscera when in reality it will be found on careful inquiry to be due to disease of the nervous system, at times, tabes at other times neoplasm of the spine or its canal or its membranes. In some instances operations upon appendix, gall-bladder, stomach, kidneys, pelvic organs have been performed, naturally without relief, the condition being found later to be dependent upon spinal disease. Dr. Elsberg expressed himself in favor of bilateral laminectomy, great care being taken to avoid manipulation of the cord, which has been found to be extremely sensitive to traumatism. Observation appears to show that the outer surface of the spinal dura is insensitive to touch, while the inner surface reacts to stimuli with a burning sensation. Also the outer surface of the cord is insensitive except in the vicinity of the origin or the posterior or sensory roots. Incision of the cord in turn causes burning pain. It was found also that in the cervical and upper dorsal portions of the spine the individual elements of the posterior roots are fairly separate and distinct before entering the dura, while in the lower dorsal and the lumbar portions the nerves enter into rather intimate union before traversing the dura. Further, in the cervical region the posterior nerves pass off in almost a horizontal direction, while in the dorsal region they first pass downward and outward and then at a somewhat acute angle pass upward and outward. Lower down they pass directly downward and outward. In rare instances an extramedullary lesion on one side of the cord may give rise to impairment of sensation on the opposite side of the body and loss of motor power on the same side, for example, if the cord be displaced by a growth and pressure exerted upon it by the bony canal on the side opposite to that on which the tumor itself is situated and perhaps separated from the cord by a serous accumulation. The operation of laminectomy is a comparatively simple one in the hands of

a competent surgeon, and it should be free from fatal results.

Drs. CHARLES W. BURR and CHARLES H. FRAZIER took part in the discussion.

Dr. WILLIAM G. SPILLER read a paper entitled "The Pathology of Tabetic Ocular Palsies." He reported a case presenting the typical symptomatology and course of tabes dorsalis, and which on postmortem examination exhibited in addition to characteristic lesions of that disease also lymphocytic infiltration, meningitis and changes in nerves usually found in syphilis of the nervous system. He pointed out that nuclear changes are not indicative exclusively of tabes or paresis, separately or in association, nor nerve changes and meningitis indicative exclusively of cerebrospinal syphilis, but that the two sets of conditions may be present in the same case. Also, clinically it is impossible in some cases to make a clear differentiation between tabes and paresis on the one hand and cerebrospinal syphilis on the other hand.

Drs. CHARLES K. MILLS and DANIEL J. MCCARTHY took part in the discussion.

Items.

The Father of Preventive Medicine.—The early history of our hero is veiled in myth and mystery. Born of a persecuted race, adopted as a foundling by a princely house, forced to flee the country for committing murder, the subject of this sketch exhibited marvelous insight and remarkable powers of administration and leadership. Although not a physician as we understand the term, and living long before the days of bacteriology, he yet was able to draft and enact a sanitary code whose guiding principles are still regarded as correct. In this code he originated an entirely new system of medicine, totally opposed to the prevailing plan. For the curative and therapeutic methods then universally followed, he substituted the more philosophic and wiser hygienic and preventive method. Moreover, in the regulations which he formulated, emphasis is laid on discharges from the body (blood, pus, mucus) as vehicles of disease, and on personal cleanliness and isolation as the chief means of preventing infection. A hygienist whose influence has made itself felt throughout the world, and the father of preventive medicine—we salute Moses, maker of sanitary laws.—*Weekly Bulletin of the New York Department of Health.*

Census Estimates.—An estimation by the Census Bureau of the population of the continental United States on July 1, 1914, puts the total at 98,781,324, an increase of nearly seven million over the population on April 15, 1910. The population of New York City on July 1 will be, it is estimated, 5,333,539, distributed as follows: Bronx, 529,198; Brooklyn, 1,833,696; Manhattan, 2,536,716; Queens, 339,886; Richmond, 94,043. The estimated gain for the four years is 566,654. The population of New York State is estimated at 9,899,761, a gain of 786,047. The population of the other large cities throughout the country is estimated as follows: Chicago, 2,393,325; Philadelphia, 1,657,810; St. Louis, 734,667; Boston, 733,802; Cleveland, 639,431; Baltimore, 579,590; Pittsburgh, 564,878; San Francisco, 448,502; Buffalo, N. Y., 454,112; Cincinnati, 402,175; Newark, N. J., 389,106; Washington, 353,378; New Orleans, 361,221; Minneapolis, 343,466; Jersey City, 293,921; Kansas City, 281,911; Rochester, 241,518; St. Paul, 236,766; Syracuse, 149,353; Scranton, 141,351; Paterson, N. J., 134,305; Trenton, N. J., 106,831; Reading, 103,361; Albany, N. Y., 102,961.

Oxygen Compartments for Travellers.—On the nearly completed railway from Arica, Chile, to La Paz, Bolivia, which goes to an altitude of 14,105 feet above sea level, the effect of the quick ascent and great altitude on people having weak or abnormal hearts is to be counteracted by having oxygen compartments in the passenger cars. Passengers subject to mountain sickness or any affection of the heart may, by occupying these compartments, breathe air having the same percentage of oxygen as at sea level.—*Scientific American.*

No More Diseases with Foreign Names.—German medical men have begun a campaign against names of diseases derived from Russian, French, or English and urge the use of a Latin or Greek term if no German equivalent exists. The *Münchener medizinische Wochenschrift* proposes that a committee should draw up a list of acceptable German equivalents for the more common terms borrowed from the enemies' tongues.

Therapeutic Hints.

Creosote, Calcium, and Phosphorus Therapy in Tuberculosis.—E. Brandenburg extols the value of this method of treatment as carried out by him at the Sanatorium Shöneberg in Sternberg. Creosote and its derivatives stimulate the appetite and have a moderate expectorant action. The author uses potassium guiaacolsulphonate, a derivative of creosote, and apparently better tolerated by the organism than the latter. Recent investigations have shown that tuberculosis is accompanied by a relative calcium and phosphorus starvation; hence the administration of these elements is indicated. Brandenburg has employed the following formula:

℞ Potassium guaiacolsulphonate, 6 grams.
Calcium glycerophosphate, 1.2 grams.
Dissolve in
Water, 50 grams.
Add
Simple syrup,
Syrup of cherries (Ger. Phar.), āā 60 grams,
Water, ad 200 grams.

The dose is a tablespoonful twice daily for adults, and a teaspoonful twice daily for children.—*Zeitschrift für Tuberkulose.*

The Treatment of Bronchial Asthma.—T. Muirhead Martin states that one should first get the patient into as comfortable a position as possible, either in bed or sitting in an armchair. All the windows should be opened and all close-fitting clothing, especially about the neck, should be loosened. Three grains of calomel with soda should be administered. It is well to burn in the room a powder of lobelia and stramonium with nitrate of potassium. Hot compresses to the chest and back and alternate (hot and cold) hand and foot baths are useful. In the majority of cases these measures calm the breathing, but if this is still distressing it may be necessary to inject hypodermically ¼ grain of morphine with 1 120 grain of atropine to lessen the severity of the dyspnea. The morphine acts as a nerve sedative, shortening the paroxysm. The atropine diminishes bronchial secretion, probably by virtue of its sedative, vagal influence. Later a wet pack should be applied and should be renewed at the end of two hours. The action of the calomel should be aided by a large soapsuds enema. During the first twenty-four hours the author gives nothing but weak orange or lemon water, and keeps the patient resting until the chest has been relieved of its superabundant secretion. The drug par excellence for this is potassium iodide. For the first week the author gives 5-grain doses every four hours in a mixture containing tincture of stramonium, tolu, and extract of liquorice. At the end of the seventh day the potassium iodide is given three times a day and is kept up for three months, this time in a mixture containing sodium bicarbonate, powdered rhubarb, magnesium carbonate, stramonium, creosote, and peppermint water. After three months this medicine is to be taken at bedtime more or less for two years, and during the day the patient should receive a tonic containing dilute hydrochloric acid, arsenic, and strychnine. He is instructed to eat slowly, and if not hungry to partake only of distilled water or fresh fruit juices until hunger reappears; and to avoid table salt, except a very little in the cooking of foods. It may be necessary to establish free nasal breathing and to calm respiration by general massage.—*Clinical Journal.*

RADIUM BETA RAYS.

THE EFFICIENT FACTOR IN REPRESSIVE ACTION ON VITAL CELLS.

BY ROBERT ABBE, M.D.,

NEW YORK.

SENIOR SURGEON, ST. LUKE'S HOSPITAL.

THE extraordinary effect of radium radiation in retarding growth of cells and living organisms has never been explained.

The physical properties of this wonder-working substance are beginning to be understood, but it is such a composite agency that no demonstration has heretofore been made which assigns to any one of the several streams of particles flowing from the radioactive atoms the results, which all observers acknowledge.

The attempt I have made in this communication to elucidate the problem will, I hope, lead to further practical work.

For eleven years I have watched in vain for evidence of stimulation of tumors by radium. The rare cases where slight stimulation is seen after use of radium are many times rarer than those which exhibit the same effect without any previous treatment, or after surgical interference only. Such cases often apply to the surgeon because spontaneous increase of growth has attracted attention.

Three years ago I made experimental research in seed culture following exposure to radium at different distances, and seemed to show, though I am now inclined to think erroneously, that stimulation was seen when the distance was about an inch and a half. Less distance than that, produced destruction of life, while greater (up to four inches) caused retardation. These results I assigned to the three major rays: Alpha, with charges of positive electricity in all particles, which are credited with a range in air of half an inch at high velocity; beta, carrying negative electric charges, which have an average excursion of an inch and a half, and gamma, which are electrically neutral and travel far in straight lines. (See MEDICAL RECORD, February 10, 1912.)

Up to the time of that experiment the most practical way of studying the influence of the isolated alpha, beta and gamma rays was by accepting the known efficient distance of activity credited by scientists to them. It is evident, however, that the gamma only can be thus studied alone, because, in the alpha range the beta and gamma are passing through, and at the beta range the gamma is mixed, though the alpha is excluded.

There is, however, a far better method of separating the rays which has been known from the earliest days of radium study, namely, the effect of the magnetic field on the three rays. This beautiful demonstration, however, seems to have been confined to laboratory study with a very small beam of radium rays. With a magnetic field transverse to the beam, the stream of beta rays was shown (on a photographic plate in a vacuum) to be considerably deflected to one side—the alpha rays very slightly to the other.

After discussing the possibility of studying these isolated rays in larger bulk with Madame Curie in her laboratory last year, I decided to take up this new line of research. With her assurance that pretty nearly pure gamma rays could be obtained from radium by the interposition of one-tenth millimeter of lead, I sought to get the isolated beta of equal strength by aid of a suitable electromagnetic field.

With the aid of Professor Pegram of Columbia University, whose knowledge of the physics of radium was necessary to success, I had a strong electromagnet made. After some experimenting we worked out a device, which, tested with a fluoroscopic screen, gave us a brilliant display of isolated beta rays, on one side, and of gamma on the other, in apparently equal proportion. These were now available for study of their differing qualities.

For two years it had been my hope to experiment with living cells of known activity growing *in vitro*, when I had perfected some such method.

When I outlined this line of research to Dr. Alexis Carrel and asked his cooperation, he recognized the fundamental principles involved and offered his aid. No higher authority or keener observer could be found. He entered upon the work at the Rockefeller Institute with no prejudices or bias. Meanwhile I made some trials of the differentiated rays upon mealworms and upon seeds, beginning in January.

Later I had the cooperation of a scientist with experience in zoology and embryology, Dr. Charles Packard, who pursued his researches at Woods Hole, Mass., with my radium and electromagnet. He made some most interesting corroborative observations described later.

I find no record of successful study of the magnetically separated rays—in large quantity—though attempts have been made to segregate beams and pencils of rays through apertures in lead.

For the use of others let me describe the effective device of Professor Pegram and myself, evolved from many experiments.

But before doing so I will illustrate a method of showing complete ray separation. Four things are needed: (1) A fairly strong electromagnet. (2) A photograph plate. (3) Radium, best spread on a varnished surface, backed up by a half inch of lead. (4) Many little cylinders of lead about one-quarter inch long and an eighth in diameter.

Experiment I.—In a dark room place a photoplate horizontally between the poles of the magnet without the current, and arrange the lead cylinders

about the radium, all resting on the plate. (Fig. 1.)

After half an hour, develop the plate. The result will be as shown in Fig. 2—the illumination of the plate is seen with lead posts each casting a shadow radiating in a straight line from the radium and

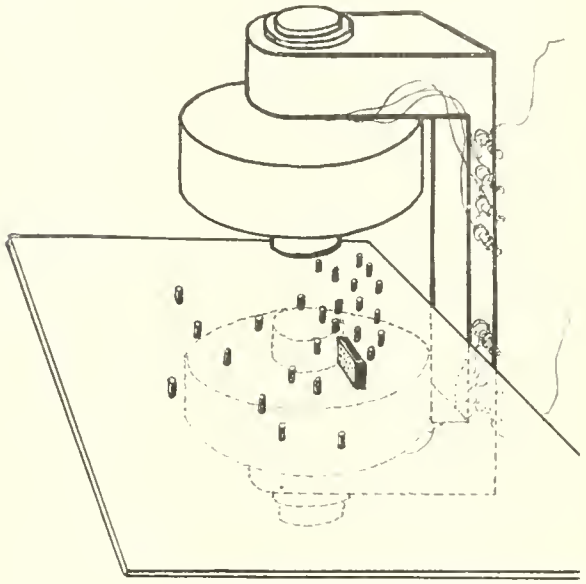

Fig. 1.

caused by all the combined rays in action. No shadows are seen behind the lead or at the sides.

Experiment II.—Repeat the arrangement and pass the current through the magnet. Instantly the beta rays are torn from their straight course, which they were traveling hand in hand with the gamma's. The developed plate now shows the shadows of the lead columns resting on the plate, displayed in two sets.* (Fig. 3.)

The pillars in front of the lead block faced with radium, still cast strong radial shadows straight from the radium, due to the gamma rays, but now shadows appear from the pillars at the side of and behind the lead block. These new shadows are due to the beta rays which have been deflected around the magnetic field.

This accords with the known path of deviated charged particles, which is in a direction tangentially deflected from the straight course and therefore describing a curved line.

If one would be more convinced of this phenomenon one should place his radium on the sensitive *x*-ray screen which he holds where the photograph plate had been. One sees an instant searchlight effect as the current is turned on or off, due to the illumination of the screen by the beta rays—separately. This brilliant and convincing exhibition will repay the trouble and stimulate thought.

A device for utilizing these separated beta rays was now invented by Professor Pegram and myself and is shown in Fig. 4.

A block of lead is so shaped that when radium is placed in a groove at one side, and a shelf made laterally with an inch and a half of solid lead between it and the radium, the gamma rays are practically shut off on that level. Below the radium a thin lead screen one-tenth millimeter thick shuts off beta rays and allows gamma only to fall on the lower shelf. With this device held between the active magnets there will be a shower of nearly pure beta rays on the upper shelf and a similar play of gamma rays on the lower one. This can be shown by a piece of sensitive screen cut to fit each shelf, which becomes intensely luminous from the beta rays when the current is on and quite black when it is cut off. The gamma rays create a continuous illumination of the lower screen. This working device was now put into service as follows:

1. Mealworms were put in paper cages covered by netting and subjected to beta and gamma radiation separately for an hour and studied for several months afterward.

Fig. 2.

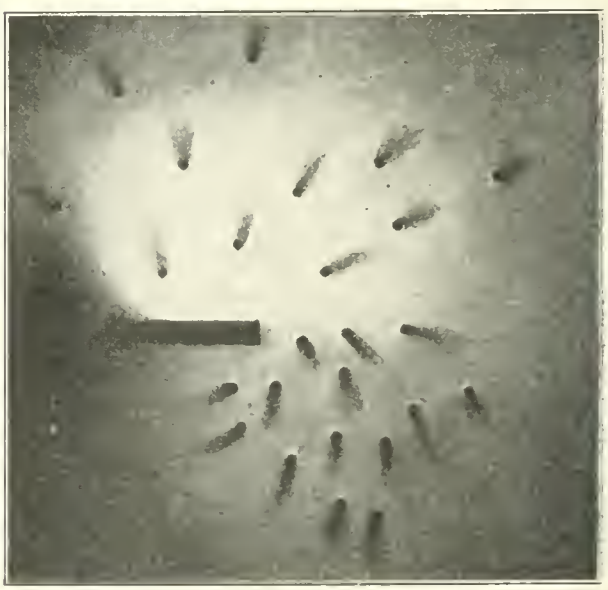

Fig. 3.

*The photograph gives a surprising proof of the generation of secondary rays by the impact of all the rays against a barrier. At the front of each lead column will be seen a brilliant white spot. This is due to the impact of myriad particles generating more rays. It has usually been asserted that gamma rays detained by a lead screen create intensification and burning effect on the skin; hence, as Wickham and Dominici have insisted, many layers of paper must be interposed to prevent unpleasant burning. It is evident from these clear pictures that it is not the gamma only, but beta rays, for in the shadows made by exclusive beta, even behind the lead block, there is the same bright spot due to secondarily generated rays.

2. Prolonged study of cell growth in vitro was made by Dr. Carrel. He used the identical tissue and technique which has demonstrated for three years, and through more than three hundred generations, the persistent and unvarying growth of cells from one stock. This could be relied on to show any change which beta or gamma rays might cause. He adopted my suggestion of extremely thin mica instead of the usual glass cover of the cell, thereby allowing penetration of even the weakest beta rays.

3. Seeds of wheat were exposed and planted with others for control.

4. Research by Dr. Packard was carried on with the same magnet, radium, and lead device during the past summer, using fertilized eggs of the sea urchin, eggs and larvæ of flies, and other objects.

From these initial studies conclusions can be made which are corroborated by independent and competent observers.

These demonstrate that *beta rays are the efficient factor in radium repressive action on vital cells.* This has been equally shown through the use of our apparatus in the varied work of all these observers. Moreover, there has been observed no stimulation in tissues submitted to beta and gamma rays separately.

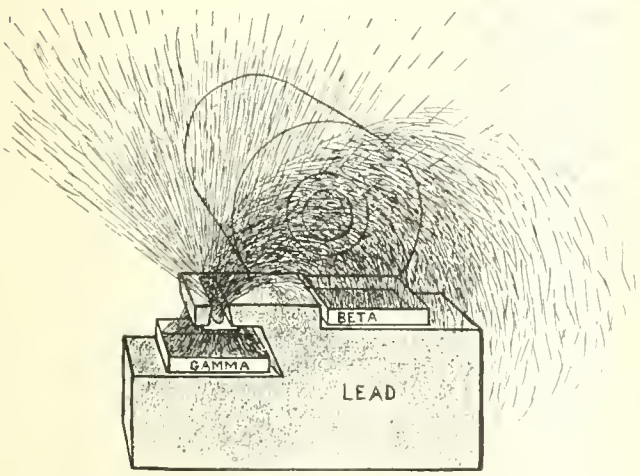

FIG. 4.

In Dr. Carrel's delicate daily measurements of growing cells the beta rays repressed growth 25 to 50 per cent. The gamma rays showed no retardation worth noting. There was no morphological change in the cells, but only in rate of growth. An important incidental observation showed that *the retarding influence persists through twenty generations* at least after radiation, showing no return to the normal, as has always happened after other temporary deterrents, such as change in temperature, nutrition, or environment.

The influence on mealworms under beta rays was corroborative and showed a slight delay in their time of changing to beetles in the few experiments made.

My experiments of three years ago, trying to disclose any point of stimulation on oats or wheat after general radiumization, were repeated and elaborated and my conclusion must now stand, that no stimulation was shown. A thousand wheat grains were placed on seven shelves of mosquito netting an inch apart, and above the top one, 250 milligrams of radium bromide was placed at one inch distance. Some seeds were removed every day from each shelf during one month and put aside to be planted simultaneously with non-radiumized controls. After growing one month they were gathered in bundles and studied. No stimulation was noted anywhere, judged either by time or distance. The universal effect was depression of growth exactly in proportion to both time and distance. The greatest destruction of seed life was at one inch. Only 7 per cent. of these seeds even sprouted and made a feeble attempt to grow. All normal seed growth was uniformly healthy, but in number and size the proportion of a like number of planted seeds after radium was as follows:

At 1 inch	7%	survived
2 "	33%	"
3 "	50%	"
4 "	85%	"
5 "	90%	"
6 "	90%	"
7 "	90%	"
No radium	100%	"

So much for the combined-rays effect.

The segregated beta and gamma effects were only given for eight hours and the results were not striking enough for conclusions. A much longer exposure would have been wiser.

As seed life is less sensitive than cell life it is with special pleasure that I can record the biological experiments of Dr. Charles Packard. The following is his own account of these experiments:

"The following experiments on the effects of the beta and gamma rays were made at the Marine Biological Laboratory at Wood Hole, Mass., during the summer of 1914. They deal chiefly with the effects of these radiations on the early development of two marine invertebrates, *Nereis limbata* and *Arbacia punctulata*, since the process of cell division at such a time is most easily affected and the resulting changes most readily observed. The procedure of the experiments was as follows: (1) The unfertilized eggs in small glass chambers were placed under the beta and the gamma rays for varying lengths of time, then fertilized with normal sperm, and their subsequent development noted. (2) Fertilized eggs were exposed for varying periods, both immediately after insemination and after the process of fertilization had proceeded for some time. (3) Ripe sperm was radiated and mixed with fresh eggs. Other experiments were made on the developmental stages of the fruit fly (*Drosophila ampelophila*) and on *Paramœcium aurelia*.

"In general it may be said that the beta rays from 50 mg. of pure radium bromide produce well-marked effects, while the gamma rays bring about no appreciable changes. Numerous experiments show that the beta rays bring about a retardation in the rate of cell division, but that the effect is not uniform in different organisms. The sea urchin egg is readily affected; the egg of Nereis is affected only with fairly long exposures; Paramœcium is not affected at all.

"Retardation is permanent. Thus the fertilized sea urchin egg after one hour's exposure may lag behind the control by as much as twenty minutes, and fall still further behind during subsequent development until at the end of five days the larva is at least twenty-four hours behind the control. Such embryos are normal in appearance. So marked an effect does not occur in Nereis, although some retardation is evident. This effect of the beta rays is most strikingly seen in fertilized eggs which have been exposed immediately after the fusion of the sperm and egg nuclei. Apparently the egg is most

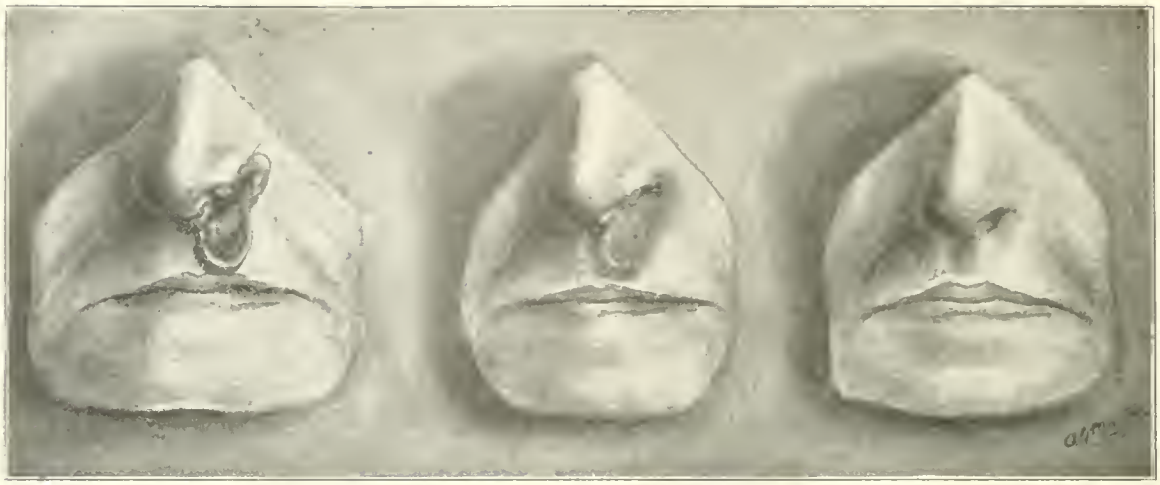

FIG. 5.
Epithelioma of the nose and upper lip, showing diminution at the end of two weeks, and disappearance at the end of five weeks. (Reprinted from MEDICAL RECORD, Oct. 12, 1907.)

sensitive during the time of actual cell division and the preceding period when nuclear activity is at its height. Unfertilized eggs may be treated for longer periods and show slighter effects.

"The gamma rays from 50 mg. of the pure bromide produce no appreciable effects. Exposures for two hours do not change the rate of division or the growth of the embryo in any way. The larvæ and pupæ of the fruit fly, as well as the imagos can be exposed for very long periods and still develop normally. The imagos are perfectly fertile.

"The distance of the object under treatment from the radium is an important factor in the character of the effects produced. In the device used in these experiments the object was about 35 mm. from the radium, and the path of the beta particles was much longer. Eggs exposed to the combined beta and gamma rays at a distance of 50 mm. from the radium showed the same phenomena of retardation which have been described above. At shorter distances the retarding effect became less evident, while marked protoplasmic changes appeared. This is evidently an effect solely of the beta rays operating at a short distance. The egg membrane and the cortical layer of protoplasm in the Nereis egg lose their firm consistency, the latter becoming so

FIG. 6.
Same patient as represented in Fig. 5, showing permanence of cure by radium after nearly ten years.

fluid that it flows out freely when the membrane is punctured by a glass needle about one micron in diameter. This effect is probably greatest in the unfertilized egg. Such eggs after fertilization divide very abnormally a few times and then die. Sections show that the chromatin also is much affected. Fly pupæ placed directly on the radium (the alpha rays were excluded) grew normally and hatched, but the adults failed to form either eggs or sperm.

"From these experiments it appears that the beta rays from 50 mg. of pure radium bromide acting at a distance of about 50 mm. produce a retardation in the rate of cell division in the early development of the sea urchin and Nereis. The chromatin is more affected than the protoplasm. At shorter distances (2 mm. to 30 mm.) the effect is more pronounced and appears chiefly as a marked softening of the protoplasm, accompanied by very abnormal cell division. The gamma rays produce no appreciable effect."

It would be an error to say that equal potentials of gamma and beta rays are used in these experiments. The main idea has been, thus far, to differentiate the kind of action each exerts.

No measurements were made of the absolute quantity of beta and gamma energy, absorbed by the tissues experimented on.

The results of the experiments relate, so far as the quantities of energy are concerned, on the one hand, to that absorbed by the several tissues when placed in gamma radiation of the intensity to be found at a distance of 20 millimeters from the glass wall of the tube 1 10 mm. thick, and 1/10 mm. of lead being interposed—and, on the other hand, to the corresponding quantities of energy absorbed by the tissues when placed in beta radiation of the intensity to be found at a distance of 35 mm. from the radium (26 mgr. radium element), the 1/10 mm. glass wall of the tubes and intervening air being interposed.

Interpretation.—Growing tumor cells of certain types are arrested in their disorderly career by the play of certain rays issuing from radium.

We come a little nearer to understanding *why* this occurs, when we differentiate one special kind of ray and find that this retarding power resides in it alone.

The beta rays are responsible for checking the tumor. The permanence of this phenomenon is shown by Dr. Carrel's demonstration of the unprecedented continuance of the influence through twenty generations. This is corroborated by Dr. Packard's work on eggs and larvæ and by my own recent and former notes.

The generation of secondary rays by both beta and gamma is of itself of interest in this demonstration.

The known effect of gamma rays in producing secondary betas on meeting resistance, coupled with their greater penetrating power—a hundred times greater than that of beta—adds to our understanding of its action on deep structures.

It would seem probable that it is the evolution of these new secondary beta rays in the deep structures, that can be considered the agent of greatest efficiency in radium work.

But most important of all is the permanence of results in curing destructive growths on human beings.

I will select one out of hundreds from my note book. It is an interesting one, because it was quickly cured ten years ago, and I have lately seen the patient for the first time since then. I marvel at the perfection and health of the little scar and submit the recent photograph.

The basal-cell epithelioma had been eating away the lip and nostril for seven years. A few hours' treatment by radium cured it in five weeks. It has never recurred.

The illustrations are taken from an early report of the case (MEDICAL RECORD, October 10, 1907), Fig. 5, and the later photograph, Fig. 6, shows the condition nearly ten years later.

Conclusion.—Separated beta rays from radium are demonstrated to be the efficient force most active against living cells.

These rays are electrons or particles discharged from the radium atom, each bearing a charge of negative electricity.

What the force is which actuates living cells is unknown, but it adds one link to the chain of facts to know that a charge of negative electrons carried into certain types of disorderly growing cell tumors reduces them to orderly growth.

The permanency of this checking force is established.

IMBEDDED RADIUM TUBES IN THE TREATMENT OF CANCER.

WITH REPORT OF A CASE OF SARCOMA REMAINING CURED NINE YEARS AFTER RADIATION.

BY WILLIAM JAMES MORTON, M.D.,

NEW YORK.

LATE PROFESSOR OF DISEASES OF THE MIND AND NERVOUS SYSTEM AND ELECTRO-THERAPEUTICS, NEW YORK POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL.

IN cases of cancer, in radium therapy as in surgery, a record of the permanency of favorable results is of prime importance. The patient here referred to remains well at the end of nine years, and may therefore be said to be "cured." Attendant points of interest are the utter hopelessness of relief by other measures, the method employed of low radioactivity and length of time of exposure, a Roentgengram of the imbedded tube *in situ* showing even the radium salt within the tube, and a recent Roentgengram showing the healed humerus.

The case was tentatively reported as an "apparent cure at the end of two years," in the MEDICAL RECORD of November 9, 1907, in a general article which covers essentially the entire ground of radium therapy as practised to-day, with the single exception of the elaboration of the system of filtration of the rays. A much condensed record from my private note book and from the records of the hospital, follows:

Miss L. V., aged 22. May 17, 1905. Referred by Dr. William Kemble of Kingston, N. Y. About one year previous to this date the patient noticed a swelling about the size of a walnut in the region of the upper third of the humerus. In six months the growth gradually increased to the size of a lemon. Accidentally striking her arm against a hard object a fracture occurred at the site of the tumor. The patient went to a hospital and a part of the growth was removed and pronounced to be cancer. A large tumor grew at the site of the incision and she then visited Dr. Kemble who removed portions and had slides prepared at the Pathological Laboratory of the Post-Graduate Medical School. These were submitted to Dr. H. T. Brooks, who reported that they exhibited the "histological features of sarcoma of spindle-cell variety." The tumor was fusiform in shape, four inches in length, and two and one-half inches in width at its greatest diameter. Following the two operations an opening freely discharging pus remained, large enough to admit of the introduction of a finger to a considerable depth. The patient had emaciated rapidly, had lost her appetite, presented extreme cachexia, and her skin was of a yellowish and sallow hue. No hope whatever was entertained of saving her life, but as a last resort amputation of the arm at the shoulder was proposed. This was rejected both by the patient and her mother. At the site of the growth, what little bone had survived the ravages of the disease had undergone spontaneous fracture and a splint was required for support.

Soddy had sometime earlier suggested that a tube containing radium might with advantage be introduced within a malignant tumor. Radium salts of high radioactivity were not, as I now recollect, at that time (early in 1905), available, at least in this country. But I pos-

FIG. 1.—Radiograph taken at the beginning of treatment showing the radium tube within the tumor, the radium within the tube and the state of fracture.

sessed a glass tube of radium chloride containing 100 milligrams, of an estimated radioactivity of 20,000. This tube gave excellent radium skiagraphs and I determined to insert it within the opening referred to and placed the patient in the Post-Graduate Hospital. The tube remained continuously within the wound for about six weeks. Within ten days there was a very great diminution of the discharge. At the same time the pain, which had been severe, ceased. Within five weeks the patient was able to dispense with the splint which she had worn constantly with heavy bandages and could move the arm freely and walk about. She had gained seven pounds in weight in a period of the first two weeks and showed every sign of returning health and vigor. The cancer growth receded steadily. About six weeks from the beginning of treatment the patient was discharged from the hospital and the tube was removed permanently, owing to the development of a severe second-degree radium dermatitis. This was represented by a vivid hyperemia, in places of a dusky hue, associated with a burning seasation and itching. The hyperemia extended peripherally outward from the focus of the wound, reaching almost to the elbow. Necrosis of the tumor tissue with breaking down and discharge occurred with a rise of temperature, on one day to 104° F., due to absorption of toxic material. These cases of severe toxemia due to intensive raying and consequent resorption of decomposition products, with fever, nausea, vomiting, exhaustion, and fatigue are now well recognized and will be again referred to below. From this moment complete recovery was established. At the end of three months the wound after discharging less and less freely was nearly healed. The opening closed entirely in March, 1906.

I shall not at this moment encumber this brief communication with the results of quite a number of other cases. Suffice it to say that one of these,

Fig. 2.—Radiogram taken two years after. By this time the patient had recovered the full use of her arm. Negative accidentally broken

"Case II, Carcinomatous tumor of the knee," also reported in the Medical Record of November 9, 1907, with skiagraph of imbedded tube at the time of treatment made continuous and rapid improvement, gained eleven pounds in weight, was relieved of all

Fig. 3.—Radiograph taken October 10, 1914, more than nine years later on.* The patient is in perfect health and has no disability of the arm.

pain, regained the flexibility of the joint, showed no further evidence of tumor growth, and was discharged apparently well. I am informed that some years afterward the patient died of general carcinosis. Another case, treated in 1907, but not yet reported, presents in brief this history:

Primary carcinoma of the breast of the size of a large egg. Operation firmly refused. An incision into the center of the tumor was made for me by Dr. James N. West of this city. Misroscopic examination of a piece of the tissue removed established the diagnosis of carcinoma. Into this incision I inserted a tube containing ten milligrams of pure radium bromide of an activity, as was the custom at that time to estimate it, of 1,800,000. The tube was left in place sixteen hours. A severe radium necrosis ensued, very slow to heal. Some time later on it was thought best on account of the slow healing of the wound simply to remove surgically the mammary gland involved. Microscopical

*Radiograph, Fig. 3, was kindly taken for me by Dr. Eben Clayton Hill, radiographer to Vassar Hospital, Poughkeepsie, N. Y., where the patient now resides. In his letter of October 17, 1914, Dr. Hill writes: "The woman uses that arm as if it had never been diseased and yet the plates even now show how far that sarcoma had affected the humerus." It is to be regretted that the delicate structural lines of the tumor as shown in the negatives are lost in reproduction.

examination showed, as reported by the surgeon who operated in a distant city, remaining cancer cells in the periphery of the broken-down area. The patient at this date (1914) seven years later has never shown any signs of recurrence of the disease and remains in perfect health.

That cancer cells, at some distance peripheral to the central influence of radium rays, may retain vitality for a time and yet lose their capability of proliferation, has now been established by the researches of von Wassermann. It is probable, therefore, that the patient would have made full recovery even without the comparatively minor operation resorted to.

As bearing upon the use of radium and of other radioactive elements some general considerations are not out of place. That the alpha, beta, and gamma rays of the radioactive elements are the sole and only known demonstrable means of effecting a deterrent influence upon the vitality and the proliferative power of cancer cells is now established beyond doubt. The extreme effect of all or any of the three classes of rays upon animal tissue is caustic and destructive, whether the cells be cancerous or not. A lesser effect is biological and concerns itself with the life history of the cell to the extent of inhibiting either its viability or its proliferation, while a milder effect still is to stimulate the cell growth; but how these rays act is unknown, as unknown as is the cause of cancer. It may be, as W. S. Lazarus-Barlow argues,[1] that an immunity is created by reason of a production of antibodies and autogenous vaccines. There is some strong evidence of this derived from practical work. For instance, affected glands and secondary skin nodules at a distance from local radiations have been known to return to normal.

Again, the action of radiation upon cells is selective in the sense that the normal tissue systems react in well recognized gradations. For instance, the testicles and the ovaries have an extreme affinity for radiation and sterility is produced. But further, the cancer cell reacts as fully, if not more so, than any normal cell. Thus rat sarcoma is twenty-four times more vulnerable to radiation than are leucocytes.—(Lazarus-Barlow.)

As to dosage, the radiotherapist has the choice of a small quantity of radioactive substance used over a long period or a large quantity over a short period. He may use five milligrams of a given radium salt twenty times as long as one hundred milligrams. Undoubtedly modern consensus of opinion is in favor of the massive dosage, viz., large quantity and shortened duration. But here a grave question meets the operator. So much cancer tissue may be caused to undergo necrosis that the patient may succumb to a resulting toxic effect due to the absorption of the necrosed material. This has been clearly proven by the experiments of A. v. Wassermann[2] in mouse tumor treated by chemotherapy. In the case of tumors which had reached the size of a plum, if the breakdown of the tumor occurred rapidly the animal quickly sickened and died, while under a slower action the tumor, after liquefaction, was gradually absorbed. This happened regularly and left no doubt in the experimenter's mind that the animals died owing to the toxicity of the reabsorbed tumor mass.

Herein will lie in many cases a favorable or unfavorable result, depending upon the expert knowledge and good judgment of the operator. In cases of large tumors quickly necrosed by over-massive doses of radium, it may well be that the issue of death has been determined by the sudden influx of the necrosed material thrown into the economy.

All the above and many more considerations must be taken into account in imbedding tubes of radioactive elements in cancer tissue. By this method all that is valuable in radiotherapy is retained, while there is an advantage in not being obliged to protect intervening normal tissue and thus limit a desired dosage. Indeed imbedding the tube is an intensive radiotherapy and must come more and more into practice.

MICROSCOPICAL TRAUMATIC LESIONS OF THE MUCOSA FOUND IN SOME RECENT CASES OF APPENDICITIS.

By CARLO SAVINI, M.D.,

NEW YORK.

In 1892 Talamon called attention to traumatism in the etiology of appendicitis. He thought that relatively large foreign bodies, directly lacerating the mucosa, or indirectly favoring stagnation in the appendix and alteration in its blood supply, were responsible for the greatest majority of appendicites.

In our days, of the theory of Talamon nothing remains but an historical interest. Although it is possible that a wound produced in the mucosa by a large pointed foreign body may be the starting point of appendicitis, this occurrence is very rare, and the origin of the disease is attributed to many other factors.

Very often, in the microscopical examination of specimens of recent appendicitis, I found lesions which appeared to me as of a traumatic origin, and I have tried to find an explanation of this fact. This report is to bring in evidence that in some cases the initial lesion in appendicitis consists in small wounds in the mucosa, produced most probably by very minute sharp foreign bodies that usually reside in the appendix.

The specimens used for this study were obtained in the 244 operations for different lesions of the vermiform appendix, which I performed in my private hospital since January, 1907.

To insure a good examination, I have taken the precaution during the operation to handle the appendix with great care. Soon after the operation the specimens that were to be sectioned for microscopical examination were split open in a line opposite to the insertion of the mesentery. Only those appendices were left intact which, being atrophic and obliterated, were very difficult to cut open.

The splitting of the appendix is not approved by some pathologists, but in my opinion it is a necessary procedure. It permits the macroscopical inspection of the specimen, which is of the greatest importance, and thus the area most affected can be selected and isolated for further microscopical examination. Besides, in the split appendix the fixing fluid is brought into better contact with all the specimen.

As fixing fluids I used alcohol in different degrees of concentration, and the fluid of Carnoy. The pieces were imbedded in celloidin. Sometimes I stained the pieces in mass, but generally the sections

were stained separately with different solutions: boric carmine, hematoxylin and eosin, and with a solution of toluidin blue.

In the very first stages of appendicitis the only lesion revealed at the macroscopical inspection is an

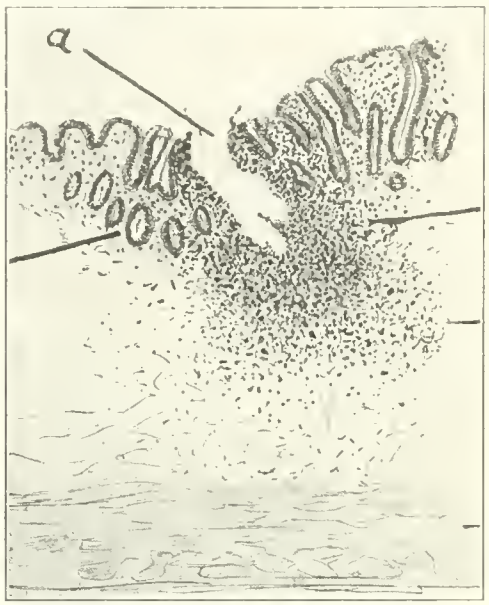

FIG. 1.—The initial lesion in appendicitis. a, abrasion of the glandular layer; b, Lieberkühn glands distorted; c, cellular infiltration; d, submucosa infiltrated; e, muscularis.

ecchymosis that occupies a limited part, or limited parts of the mucosa. Microscopically observed, this ecchymosis shows as a solution of continuity, an abrasion, of the glandular layer of the mucous membrane. In many cases this abrasion is so limited and its margins are so sharp as to appear to be an injury produced by a traumatic agent as, for instance, by a cutting instrument.

The Lieberkühn glands, which represent the most internal layer of the mucosa, are partially destroyed at the site of this abrasion, and are normal in its vicinity. This initial lesion is surrounded by a great amount of cellular infiltration which expands from this lesion as from a center on all sides in the submucosa and toward the lymphoid follicles.

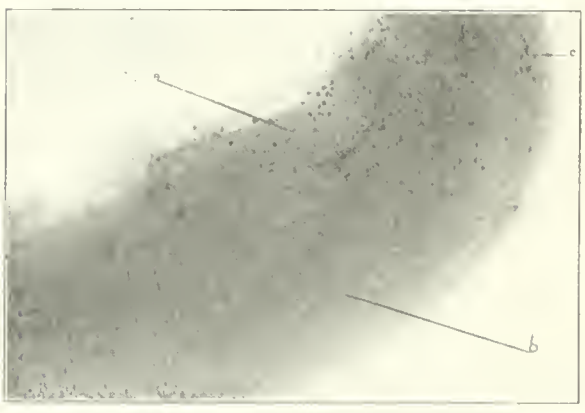

FIG. 2.—Skiagram of a specimen of appendix affected with empyema enlarged about 100 times; a, small foreign bodies; b, situation of the necrotic area without bodies; c, fundus of the appendix.

In a section a little distant from the initial lesion, it is possible to find infiltrated only the submucosa, and over it the glandular layer perfectly normal. By the observation of this fact some pathologists have been led to believe that the initial lesion of appendicitis was the infiltration of the submucosa or the inflammation of the lymphoid follicles.

In transverse sections of specimens of very recent appendicitis the tubuli are placed regularly and cut longitudinally in the greater part of the preparation, but, in the immediate vicinity of the initial lesion (the destruction of the glands) the cellular infiltration separates the tubules from each other.

In more advanced appendicitis the infiltration grows greater, and in consequence the tubuli are not only displaced, but also distorted in an irregular way. And in transverse sections of these specimens the tubuli, instead of appearing regularly disposed and cut longitudinally are cut transversely and obliquely. The interposition of the cellular infiltration is responsible for their displacement.

The lymphoid follicles take part in the inflammation as do the other elements of the appendix, more so when the lesion happens to be in the glands near the follicles, but I could never detect that they are primarily affected in the recent disease.

More or less also the other layers (muscularis and serosa) are found infiltrated.

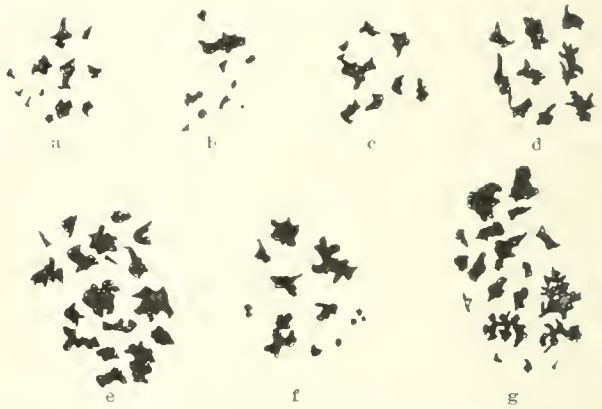

FIG. 3.—Foreign bodies obtained directly from the internal cavity of diseased appendices and from the sediment of appendices destroyed with antiformin (Oc. 2. Ob. 4mm.); a, b, c, d, were obtained by washing the mucosa with alcohol; a, specimen of gangrenous appendicitis, operation August 27, 1913; b, empyema of the appendix (this specimen was used for the *x*-ray picture), operation May 1, 1910; c, acute inflammatory appendicitis, operation September 16, 1913; d, acute gangrenous appendicitis with ulceration of the cecum, operation February 2, 1914; e, f, g, from the sediment of three specimens of gangrenous appendicitis destroyed with antiformin; e, operation January 17, 1913; f, operation June 16, 1913; g, operation September 22, 1914. The figures d, e, f, g are enlarged to bring in evidence the cutting edges.

This destruction of the mucosa has been differently explained by different observers. Some have thought that this lesion was artificial and due to a defect of the preparation, others that it was consecutive and secondary to an inflammation of the lymphoid follicles.

It is easy to demonstrate that the lesion is not an artificial tear in the preparation, by the observation of the surrounding cellular infiltration. That it is not always dependent upon and consecutive to an inflammation of the submucosa and of the lymphoid follicles is proved by the finding of this lesion at a distance from the follicles, and by the fact that the destruction of the tubuli proceeds from the lumen of the appendix toward the submucosa. In some specimens it is possible to find destroyed only the most internal part of the tubuli, the fundus being intact and the neighboring lymphoid follicles normal and unaffected in any way by the inflammatory process.

To ascertain the possible cause of this initial lesion I have resorted to the use of the *x*-rays and to direct researches in the appendix.

X-Ray Examination.—I have exposed some diseased appendices to the *x*-rays produced by a Bartlett tube for three and four seconds at a distance of 18 inches. I have printed the image thus obtained enlarging it about 100 diameters. This skiagram (Fig. 2) shows the presence of a great number of small bodies occupying all the area of the appendix but especially numerous in the fundus of the organ. These bodies are found less abundant in the place where the main lesion of the appendix is found. This dislodgment is due evidently to the suppuration and consecutive destruction of the mucosa in the place of the lesion.

In the first experiments it seemed clear to me that the punctiform shades in the picture were produced by small metallic bodies. But other enlarged *x*-ray pictures, made to determine the appearance of the diseased appendix, and the appearance of the shape and position of various microscopical substances gave results so contradictory that now I doubt that this skiagram is a proof of the presence of foreign bodies in the appendix.

Although the first interpretation was based upon an hypothesis which I could not yet verify to my satisfaction with experiments, and which most probably was not real, it has suggested the search for small foreign bodies in the lumen of the appendix.

Direct Research in the Diseased Appendix.—The specimens used in this research have been kept in alcohol.

The appendix is opened in all its length, and the mucosa is washed in alcohol with the aid of a camel's hair brush. The liquid obtained is centrifugated, and the sediment examined under the microscope. This method brings in evidence the foreign bodies free in the surface of the mucosa.

To reveal all the bodies which might be concealed in the folds of the mucosa the whole appendix is immersed in antiformin, and left in contact with the fluid for a week. In this time all the appendix is destroyed. The residuum is then well mixed, left to deposit, and decanted. The sediment is successively washed with hot water, alcohol, and ether, decanted and centrifugated each time, and finally examined. The quantity of sediment obtained in this way is large enough to be recognized by the naked eye as being of a gritty, sandy, or metallic composition.

At the microscopical examination, the sediments obtained in the two preparations appear as formed of small black bodies of various shape. Some of them are round, some quadrilateral, some triangular, and many quite irregularly formed. (Fig. 3.) Their diameter is 10 or 15 micromillimeters, some of them are larger, and a few are about one-tenth of a millimeter in diameter.

These bodies are so numerous and so heavy, that they could be separated without centrifugation, and they can easily be detected with the microscope in the bottom of the glass receptacle used for the destruction of the specimen, after the liquid has been removed.

To determine the nature of these foreign bodies, I introduced a small magnet in the microscopical field. This experiment, which must be carried out under the microscope, is difficult and the results were not satisfactory. The greatest number of the bodies were not attracted by the magnet, a few small bodies seemed attracted. But the results were not demonstrative.

The chemical tests were more conclusive:

I added a drop of aqua regia to the preparation dried over a slide, and examined with the microscope. I noticed that the great majority of the bodies were not affected by the reagent, but a few of them were very vigorously attacked, and that yellow ferric chloride was formed with abundant eruption of bubbles of hydrogen.

A short time after, a few drops of a solution of potassium ferricyanide were introduced in the preparation and in the areas occupied by the ferric chloride prussian blue was formed and revealed by its characteristic color.

Even when the quantity of iron is so small that the yellow color of the ferric chloride is hardly visible, the addition of the potassium ferricyanide solution produces an intense blue coloration, and thus reveals the presence of the most minute particles of iron.

This reaction proves that these foreign bodies are for the most part slivers of coal containing a small quantity of iron.

Conclusions.—In the cavity of some diseased appendices is found a great number of foreign bodies of very small dimensions, sometimes with very sharp cutting edges, composed of carbon with particles of iron.

It is most probable that these bodies may occasionally produce a traumatic lesion in the mucosa of the appendix, favoring the entrance of pathogenic microorganisms into the layers of the appendix, and causing various degrees of inflammation and necrosis.

31 Washington Square West

REPORT OF A CASE OF MYXEDEMA ALLIED TO THE INFECTIVE EXHAUSTIVE GROUP.*

By EDWARD F. LEONARD, M.D.,

CHICAGO, ILLINOIS.

INSTRUCTOR IN NEUROLOGY, COLLEGE OF MEDICINE, UNIVERSITY OF ILLINOIS. FORMERLY ASSISTANT PHYSICIAN, JACKSONVILLE STATE HOSPITAL, JACKSONVILLE, ILLINOIS.

I REPORT this case, not to bring forth any new symptomatology, but on account of its rarity; it being the first one of its kind admitted to the Jacksonville

FIG. 1.—In health

State Hospital. During the last twenty-five years many cases of myxedema have been described, particularly in England and America. But, although many cases have been reported, in most of them appropriate treatment was instituted before they

*Read at a meeting of Alienists and Neurologists held under the auspices of the Chicago Medical Society, June 23-25, 1913.

reached the stage necessitating removal to an insane hospital.

The disease was first described by Sir William Gull in 1873 as a "cretinoid state supervening in women"; and Dr. William Ord named it myxedema in 1878. Later Charcot—who described it under the name of "cachexie pachydermique"—met with the disease in the male. In 1894, in a compilation of 127 cases of myxedema, Heinsheimer found only ten men, or 7.8 per cent.

A number of papers have been published on this subject by different writers, but the most exhaustive communication on it is the report of a Committee of the Clinical Society of London that was nominated in 1883 and reported in 1888.

We have here an interesting case: R. N., male, 32 years old, admitted to the Jacksonville State Hospital, February 11, 1913, who is a school teacher, married, and has two healthy children. Present attack began five years ago, following mental shock caused by brother-in-law committing suicide, also worry over wife's illness. The family history elicits alcoholism on father's side; the father having taken the Keeley cure. His brothers, except one, use alcohol freely. Mother's family history is negative, except that she has an exophthalmic goiter. Patient's birth and childhood show nothing abnormal. He was a hard student and ambitious; had no injuries or serious diseases until present sickness. He is not syphilitic, nor does he use drugs, alcohol, or tobacco.

Present Illness.—The history states that the first change noticed was in the spring of 1908, when, after working hard at school, he would feel weak and drowsy, and seemed to be bilious. He improved slightly and

FIGS. 2, 3, AND 4.—Disease in full development (showing the large, clumsy and coarse features).

went to Normal School in the summer of that year, when he was called home on account of the suicide of his brother-in-law. The settlement of his brother-in-law's affairs, and worry over the wife's illness caused him to lose sleep; and a few days later he became delirious and was found wandering over the country. After several days under treatment, he again improved. In September, 1910, he returned to school, and was apparently all right until April, 1911. At that time he began to complain of weakness and of feeling cold, and his teachers at Normal noticed a lack of thoroughness in his work. From April, 1911 to January 27,

FIG. 5 FIG. 6

FIGS. 5 AND 6.—When admitted to Jacksonville State Hospital (showing changes in the hair).

1913, he gave up school work because of his inability to perform his duties. The writing of only a few words would cause his arm to become fatigued; and when he wrote a letter it would take him half a day to complete it, because of the difficulty he experienced in forming the letters. So, at this time, he turned to farming and other outdoor work in an effort to regain his health.

His condition gradually grew worse, and he was finally placed in a general hospital at Bloomington. He was at this hospital ten days, becoming delirious the last two days; at which time he talked incoherently; had hallucinations of hearing; thought he was going to die that evening at 7 o'clock; became destructive of glass and furniture, and was noisy during the day and night. He escaped from the Hospital through a window, and was found wandering in the country, when he was brought to the Jacksonville State Hospital.

On his admission he was a well-built man, in a weak and exhausted state. His face appeared coarse and swollen, especially the upper and lower eyelids and lips, but these parts did not pit on pressure. With the exception of a flush over the malar eminences the complexion was sallow and pasty. There was some epitaxis, and patient said he had nose bleed frequently. His facial expression was drowsy. The skin of the whole body was dry, rough, scaly, and wrinkled in places, more especially over the elbows, knees, ankles, and over the region of the tendon Achilles; and in these places there were small furrows. Patient said he seldom perspired. There were a number of warts on the left hand. The finger and toe nails were lusterless, brittle, and furrowed. The ends of the fingers were blunted, or clubbed. The hair on the head was dark in color and scanty, giving the appearance of having been pulled out; but the patient said it began to fall out two years before; it was lusterless, dry and brittle. The scalp was dry and scaly in places; and the eyebrows were also scant. The pulse was slow (60).

As I said previously, the features were clumsy and coarse, and the lips thickened. The patient said he had noticed his voice changing gradually, and thought at times his tongue was getting larger; and when eating or talking would sometimes bite the buccal mucous membrane. His movements were slow and clumsy; and the whole body showed an increase in bulk. Large pads of what seemed to be fat could be seen and felt above the scapulæ and at the sides of the abdomen. He said he felt a little nervous and weak. The respiratory and circulatory systems were negative.

The appetite has been poor; often he ate only a small piece of bread. His bowels were constipated. When the smell tests were made he noticed a difference in the tests, but could not name them correctly. The taste test, however, showed no inaccuracy. The tactile and pain senses were blunted, and there was some tenderness of muscles and nerves of the upper and lower extremities. The stereognostic sense was blunted. He said his fingers felt all thumbs, and it

took him considerable time to name objects in his hands. Sense of position, coordination and Romberg tests were good. The pupils reacted readily to light and accommodation. The masticatory and facial groups were normal. His articulation was indistinct, thick and monotonous, his speech was slow and labored.

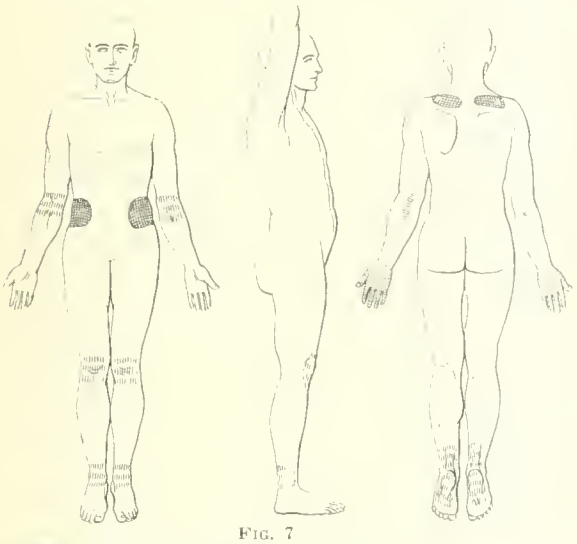

Fig. 7

Position of so-called "pads of fat."

Position of rough, scaly, and wrinkled skin.

Fig. 7.—Areas of rough skin and so-called "pads of fat."

The muscles were large, and the grip good. The hands and the calves of the legs were large. There were slight tremors of fingers and tongue. The gait was slow, labored, and stooping. There was nothing abnormal in the superficial or deep reflexes.

He has advised me recently that at times when he looked at a distant object it would seem to be at a much greater distance than it really was; also that he had difficulty in getting around in the dark, as he would run into the furniture, etc. He also said that when he felt a little bit cold he would experience great difficulty in putting on a collar or buttoning his clothes.

Although the patient cooperated fairly well during the physical examination, it was necessary to have an attendant with him, as he would get up and try to leave the room, saying: "They are calling me. There is a call for me. Let me go down there. I want to go right away. I want to go. It is getting about time for my train" (showing hallucinations of hearing). Again he said: "I want to go and see my brother. He is only going to live a few minutes. I don't want to be in here with my brother down there. We can postpone this examination." Another time during the examination he said: "Listen, I have to go out there! Let me down. Ask the gentleman there at the door if there isn't someone calling for me," and it was only after much coaxing and telling him no one was calling him that the examination could be continued. Another time he said: "Here, he is in there, I have to go. It is time now for the train to go. Let me go now. I can make the train all right if I go now. This examination won't do me any good."

Mental Examination.—Although he was quiet when admitted to the hospital, he became very restless, talkative, and hallucinated that evening, saying: "My brother is calling me," also "I am the Lord." He would not stay in bed, and it was necessary to transfer him to a disturbed ward. He refused to take nourishment.

Delusions.—"I to-day repeat, I am the Lord. The cause of my physical condition to-day is that someone has been persecuting me; and that I have been unwillingly given drugs I didn't know anything about; it had been fixed up for me. There has been considerable poison run through my system for their own personal benefit."

Fig. 9.—After 5 months under thyroid (return to health)

Hallucinations.—"I can hear voices; I can hear individuals, it seems I can hear a long distance away. A man claimed to be in Springfield, another in Jacksonville, Florida, another in Manchester! I talk to them; I can hear them speak. I have a wireless line in my head; a battery is there, and I can talk to voices anywhere. Things are sent to me by wire, and I read them in the paper the next day. I call them up; I can hear them right out of the air. It seems like it comes right down. The voices come to me and say: 'You are the Lord.' I hear angels singing religious songs. I can't explain how I hear the voices. It just seems like I can hear them coming right out of the air, their voices coming to me. They also tell me what to do. They tell me not to eat. I will die at 7 o'clock."

Orientation and Memory.—Although he knew his name, occupation and town, he did not know the day, date, month or year, or when he came to the hospital. After a long pause he was able to give the year in which he was born; but did not know his age or the year he was married, and could not give the ages of his children.

Memory of Immediate Past.—When asked where he was yesterday he replied: "Over in Heaven," "I don't know when I came or with whom; I get puzzled on these things."

To Show His Confusion.—When asked to give an account of what was done for him when he came to the hospital, he said: "Well, there wasn't anything much done. I took a bath, and then my sister was hurt and—an accident occurred with which you are all familiar—my brother was hurt—there have been so many events occurred since I have been here that I—that it has kept me in such a turmoil that it is a wonder I even lived to the present time."

Fig. 8.—After 3 months under thyroid (coarse features disappearing)

His retention was poor. His school knowledge and calculation was good.

Insight.—He said: "My mind could be worse, and I needed a little rest. There may be something the matter with it. The poisons given me is the cause of my condition more than anything else. I certainly want to get well. I don't know what line I will follow when I get well. The future alone can tell."

Urinary Examination.—February 26, 1913: Sp. gr. 1027. Acid reaction. No albumin or sugar. Indican present. Few epithelial cells and leucocytes. Few small hyaline casts. Very few granular casts.

The red blood cells were variable in size.
Wassermann test made March 5, 1913, result negative

Course and Treatment.—As he became weak from insufficient nourishment the patient was transferred to the hospital ward and placed in bed. At first he was restless, would not eat, and had hallucinations and delusions. After persuasion he began to eat, and was then given iron and arsenic, also thyroid, gr. v, t. i. d. at first, which was gradually increased to 30 grains a day. Under the thyroid treatment the red blood cells at first decreased in number and the hemoglobin lessened. The dose of thyroid was decreased, until, three months after admission to hospital, he was taking 20 grains a day. During that time the bulky appearance of the body gradually disappeared; the intellect cleared; the skin gradually became normal; the nails changed in appearance; the old hair slowly fell out, and fine, soft hair began to come in; and the gait and speech improved. Finally he began to take interest in his surroundings, and said he felt as well as he ever had. Besides the medicinal treatment, light work with the florist was obtained for him, and a special nutritious diet was prescribed. He is at present a pleasant and agreeable patient.*

Although cases of myxedema are classed usually under the heading of the intoxication psychosis, I think this case can be allied to the infective exhaustive group, on account of the physical exhaustion, anemia, low percentage of red cells, confusion, hallucinations, changeable delusions, disorientation, clouding of consciousness, and changeable emotional reactions.

ANNULAR, SERPIGINOUS, BULLOUS ERUPTION COMPLICATING VACCINATION.

By C. AUGUSTUS SIMPSON,

WASHINGTON, D. C.

ASSOCIATE PROFESSOR OF DERMATOLOGY, GEORGE WASHINGTON UNIVERSITY; DERMATOLOGIST TO THE GEORGE WASHINGTON UNIVERSITY HOSPITAL DISPENSARY; DERMATOLOGIST TO THE WASHINGTON ASYLUM HOSPITAL; ASSISTANT SURGEON, MEDICAL RESERVE CORPS, U. S. NAVY.

ECTHYMA, impetigo, and bullous eruptions complicating vaccination have claimed the attention of dermatologists for many years past and yet the subject seems most unsettled. The number of case reports has served to build up a large class of lesions that may complicate this operation but efforts to classify them have caused endless confusion. The bullous eruptions particularly are hard to systematize and efforts to do so have only served to confuse our ideas of pemphigus, Duhring's disease, and other conditions they may simulate. Jenner[1] in his first writings on vaccination as early as 1799 mentioned these accidents following vaccination and pleaded for a more careful training and technique on the part of the vaccinator.[2] Stellwagon[3] in 1883 published a splendid article on the bullous eruptions following vaccination and concluded that such an eruption had no direct relation to it. Pusey[4] in 1893 reported a bullous eruption resembling dermatitis herpetiformis following vaccination, and similar cases were later reported by Becker and Stellwagon. Schamberg[5] in 1896 had in his practice an annular, serpiginous impetigo following vaccination, but this case had the usual impetigo crusts around the mouth in the beginning, attacking the axilla and pubic region later. Bowen[6] published in 1901 his report on six cases of bullous eruptions following vaccination that closely resembled Duhring's disease. Schamberg[7] reported in 1901 a case of acute pemphigus following vaccination. Howe[8] up to 1903 had ten cases of acute pemphigus or bullous dermatitis in his practice, nine of which had been recently vaccinated. A typical case of acute pemphigus following vaccination was shown the London Dermatological Society by Sequira[9] in 1902. T. Colcott Fox* in 1907 wrote an excellent article on the frequency of ecthyma, impetigo, and bullous eruption following vaccination and the presence of pure cultures of streptococci in all the lesions. These reports are a small number of the cases to be found in the literature and other men as Wipham, Saundby, Winfield, Zeisler, Kirby-Smith, Dyer, and others have all contributed cases which have a more or less direct bearing on this class of bullous eruptions.

The above is a fair example of the difficulty of arranging a satisfactory classification of skin diseases, in this instance three supposedly different diseases being reported as complicating vaccination with closely allied clinical symptoms and etiological factors which may be considered very similar. The question of how much the personal equation has entered into the diagnosing and separation of the diseases is a point to consider. Corlett[10] states in his report of a case of erythema multiforme bullosum that at one stage it could have very properly been diagnosed pemphigus foliaceus. Hazen's[11] case in other hands would have probably been classed as a bullous impetigo, beginning as it did in typical impetigo lesions of the scalp, spreading to the body, and yielding a pure culture of *Staphylococcus albus*, probably a secondary infection. Towle[12] showed a case of Duhring's disease that many dermatologists considered acute pemphigus. Too much attention in the past has been paid to such clinical symptoms as grouping, itching, proceeding or surrounding redness, recurrences, and foliation and not enough to laboratory examination of the contents of these bullæ, autoinoculation, and animal inoculation. Many or all of the above clinical points may be brought out in cases of dermatitis herpetiformis, acute pemphigus, bullous impetigo, and bullous erythema multiforme and time only is necessary in many cases to cause one disease to become another, at least clinically. To my mind it should take more than mere itching and grouping to change a case of pemphigus into dermatitis herpetiformis as Pernet's[13] case reported in the *British Journal of Dermatology*, January, 1910. The pemphigus class probably suffer more by this inflation than any other. Congenital pemphigus

*Through correspondence I have kept in touch with this patient up to June, 1914. He is in good health, and is teaching school in the South. He is taking a 2-grain tablet of thyroid daily.

**British Journal Dermatology*, 1907, page 191.

has been placed in an entirely separate chapter of dermatology, while bacteriological examinations have convinced us of the impetiginous nature of pemphigus neonatorum and its terminal dry stage dermatitis exfoliativa neonatorum (Ritter[14]). Is it not possible to swell further the coccogenic and impetiginous group at the expense of the heterogenous pemphigus class? Hartzell,[15] speaking of the bullous lesions following vaccination, was of the opinion that they were closely related to pemphigus and he sees no reason why they should not be included in its category. Pusey[16] in his textbook goes further and places these cases in a separate chapter but still under the general heading of pemphigus. Sequira[17] apparently thinks that they conform better to the acute malignant type than to true pemphigus. In fact, from the arrangement in his book one would be led to believe that he considers them less related to true pemphigus than is Duhring's disease. It seems to me that a certain number of these so-called cases of bullous erythema multiforme, bullous impetigo, bullous dermatitis herpetiformis, and acute pemphigus deserve to be placed under an entirely different heading. By stretching the imagination the bullous eruptions following injuries, vaccinations, infections, and uncommon impetigo-like lesions may be placed with one or the other of the above diseases, but that they represent true types I believe few will admit. As Hartzell stated, the acute pemphigus class is better fitted to receive the majority of these cases than any other we may have at present, but as long as the word pemphigus is affixed there will be confusion. If pemphigus is to include these progressive bullous diseases which follow worry, nervous disturbances, and anxiety, which are noncontagious and noninoculable, our conception of it must be stretched to the breaking point in order to include some of the above mentioned cases. Enough bacteriological work has been done at this time to show the multiform organisms that are to be found in the present pemphigus group. This has led various dermatologists throughout the world to insist on this or that coccus or bacillus being the cause of pemphigus. A survey of the papers by Pernet[17] and Balloch, Bowen,[18] Demme, Bleibtreu, Corlett, Wiphàm, Du Mesnil de Rochmont, Allen Petges and Bechlonne, Towles, Hazen, and Pusey will give one some idea of the number of different organisms that produce pemphigus in one of its forms, and each particular writer seems to have a good reason for his conclusions. It may be that when laboratory methods are much further advanced and the specificity of the organisms commonly found in these skin lesions is more thoroughly understood, there will cease to be any pemphigus and each bullous eruption will have its particular etiological organism. This would necessarily cause a tremendous commotion in the present classification but it would, to say the least, place the whole category of pemphigus on a scientific and sane basis which is not the case at present. Nor do I consider the pemphigus group alone at fault in this regard, but such cases of bullous erythema multiforme following injuries and infections as Corlett's case or the quoted epidemics by Molones-Mahon, Vidal, Leloir, Rigler, Herxheimer, and Goal lead one to believe that they are not to be considered true examples of erythema multiforme but are examples of bullous eruptions caused by specific organisms. Streptococci have been found in the blood and unruptured bullæ of some of these cases and may account for some of the reported epidemics. The dermatitis herpetiformis group has also been stretched to make room for some of these bullous eruptions. Enough is known of the etiology of this disease to lead one to suspect that exposure to cold, shock, nervous exhaustion, and worry are the chief underlying cause of Duhring's disease. No specific organisms have been found in the lesions and the disease is neither contagious, infectious, nor autoinoculable. Because a bullous eruption has a few characteristic clinical symptoms, such as itching or grouping seems insufficient cause to warrant a diagnosis of dermatitis herpetiformis bullosa in cases that run a septic course and follow infected wounds as vaccinations. The reports of cases by Dyer, Bowen, Pusey Becker, and Kirby-Smith failed to discuss the bacteriological findings except to a limited degree Acute bullous dermatitis or septic bullous dermatitis seems to me a more suitable name for most of the above-mentioned aberrant forms of acute pemphigus, erythema multiforme, dermatitis herpetiformis, and impetigo. Under this heading I would like to report an interesting case that I have had in my service at the Washington Asylum Hospital.

Frank S., colored, 28 years old, born in the District of Columbia. Family history—Mother and father living and in good health, five sisters and two brothers also living and in good health. Personal history—Measles at 13, a history of repeated sore throat before that time, whooping cough at 15 with slight conjunctivitis complicating it which lasted for three weeks Gonorrhea at 19 which lasted one month. In one month and a half after the first attack the patient had another attack which gave him very little trouble and disappeared in two weeks. This preceded a sore on the upper surface of the corona of the glans penis which was pronounced a chancre at one of the local hospitals No dark field examination was made in this case. The lesion disappeared in three days after dusting it with calomel. October 15, of last year he suffered from what he terms his third attack of gonorrhea. The discharge at this time was very profuse at first but yielded to treatment and was finally cured by April 1. At this time he was confined in the District Work House at Occequan, Virginia, and was still confined in the same institution until June 16. Nine days before being discharged from this prison he was vaccinated against smallpox along with a number of other prisoners. Three days after vaccination he noticed several small blisters on his right leg and soon the back, face, arms, and chest became involved in the order named after which he was placed on my dermatological service.

On June 26, 1914, an examination of the lungs, liver, spleen, and kidneys proved them to be normal, osseous system normal, arteries compressible, muscular system well developed and normal, nervous system showing knee reflexes absent, Babinski's sign not present, cutaneous sensibility normal. Cervical, popliteal, and inguinal glands not enlarged, submental, axillary, ulnar, supratrochlear enlarged and tender, hearing normal, left iridobulbar and palpebral conjunctivitis appearing at the same time as the cutaneous eruption; temperature 100°, pulse 99, respirations 26. The patient has a generalized bullous eruption which gave rise to a sickening odor by some thought to be characteristic of pemphigus. The lesions were variable in size as the photograph shows and located mostly on the lateral chest walls and extensor surfaces of legs and arms, while the face was more mildly attacked. The axilla, scalp, flexor elbow surface, popliteal space, palmar and plantar surfaces, fingers, and toes all remained free of the eruption to the end. Some of the bullæ were as small as 4 mm. in diameter others well over 4 cm. across. The earliest bullæ were preceded by congested spots, without subjective symptoms, which within twelve hours would develop into well distended blisters with firm covering which were sharply convex, making each lesion stand out prominently as a distinct globular elevation. The older lesions tended to be somewhat more flaccid and Nickelski's sign could be demonstrated in some; a number of the bullæ retained their hemispherical character until ruptured or absorbed. After the individual lesions were 48 hours old a narrow sur-

rounding congested halo could be discerned accompanied by a changing of the perfectly clear watery contents of the blister to a purulent or seropurulent fluid, many of the lesions would persist for a variable time after this change, advancing and progressing on one border, broadening out fan-shaped, while subsiding, becoming

Fig. 1.—Annular, serpiginous arrangement of bullæ.

less active, and absorbing on the other. In some locations, as the lateral chest walls, the center and edges of some of the larger bullæ had become less active and depressed producing in places ring, crescent, and gyrate lesions which would advance in some cases two inches before finally subsiding, bursting, or absorbing. (Fig. 1.) This would cause the lesions to change their shape in a few days and lead to the formation of the most interesting gyrations. As the daily changing and spreading led to unusual configuration so would the subsidence and drying up of the eruption leave in its trail the most striking scroll-like lesions, resembling the plates of tinea imbricata or the case of annular syphilis reported by Howard Fox. The concentric rings formed by the dropping in and desiccation of the bullæ coverings persisted until the patient left the hospital, and recalled the tendency of cutaneous eruptions in the negro to undergo such fantastic scroll-like formations. (Fig. 2.) The bullous eruption persisted from June 16, until July 1. The temperature in the meantime showed a septic course and a daily variation of from one to three degrees, but at no time was it charted over 100°. Autoinoculation was not attempted, but the first lesions developing on the legs following scratching and the course of the disease would lead one to believe that such an accident played a prominent part in its spread. After July 1 the eruption began to subside, the bullæ ruptured more easily, absorption of the fluid from them seemed to be increasing, while new lesions failed to appear. These blisters that ruptured and exfoliated their coverings persisted a few days as raw, moist, secreting surfaces which soon became covered with epithelium, leaving dark stains but no scars in their places. At no time were there any signs of honeycomb stuck on impetiginous crusts to complicate the true bullous eruption which remained of one type throughout. The mucous membrane of the mouth was attacked also, the quickly rupturing lesions in this location leaving denuded, red, easily bleeding lesions and made the taking of food painful. The only subjective symptoms the patient ever complained of were stiffness and tenderness of the cutaneous surface when he changed his position. The eye condition persisted while the eruption continued to appear, but improved and had almost disappeared when the patient left the hospital. It would be interesting to know if it would lead to essential shrinking of the conjunctiva, as reported by von Grafe, Morris, and Fuchs following pemphigus. Three days after the patient was admitted to the hospital a newly formed unruptured blister was painted over with tincture of iodine U. S. P., and opened under the most aseptic conditions. Cultures were made on agar and the organism proved to be a pure growth of *Staphylococcus pyogenes aureus*. July 1 found the eruption almost healed and the patient insisted on leaving the hospital against my wishes.

Leaving aside the peculiar configuration of the eruption seen in this case, it is to me of sufficient importance to be reported in order to try to clarify the subject of bullous eruptions. Here is an eruption which certainly should not be considered a case of true pemphigus, although many such cases have been reported in the past as acute pemphigus or malignant pemphigus. The entire course of the disease suggests an infection possibly in addition to some anaphylactic reaction in a patient presensitized by vaccine and who was perfectly well before being vaccinated and infected and in whom the supposedly commonly suspected etiological factors of pemphigus played no part whatever. The staphyloccoccus grown from a prematured unruptured bulla would point to this organism as being the exciting cause of the eruption. Bullous impetigo, dermatitis herpetiformis, or erythema multiforme would not enter into the diagnosis, although closely allied cases have been reported under such headings. Acute bullous dermatitis or septic bullous dermatitis seems to me to be a name more suitable than any of those given above and one which makes unnecessary the distortion of any particular group in order to classify it.

Fig. 2.—Showing scroll-like remains of the eruption with concentric rings of exfoliating scales.

ACUTE MYELOGENOUS LEUCEMIA.

BY WARREN B. STONE, M.D.,

PATHOLOGIST TO ELLIS HOSPITAL AND TO THE SCHENECTADY LABORATORY ASSOCIATION,

AND

ALBERT S. FAY, M.D.,

SCHENECTADY, N. Y.

THE various diseases characterized by changes in the blood itself are always of extreme interest, but because they are not especially rare and because the differential stain shows such a clear cut picture it is only in the so-called border line cases and in cases similar to the one we are studying that we are traveling in diagnostic fields which are still somewhat obscure and which require more cases to be studied more carefully before a proper classification can be made. In respect to etiology and treatment, the whole field of blood diseases offers most promising rewards for diligent research workers.

In 1896 Van der Wey described the first case of this condition reported in the literature. In 1903 Billings and Capps through the medium of the *American Journal of the Medical Sciences* first brought the condition strongly to the notice of the American medical profession and were able to report 9 cases which they collected from the literature. In 1910 Wolfer (*New York Medical Journal*, November 26, 1910) was able to bring the list up to 20. Since then 3 or 4 other cases have been reported so that the total list of cases is now under 25 and it is quite generally recognized as a distinct disease, although some men, even of the prominence of Adami, while freely admitting the occurrence of acute lymphatic leucemia deny the myelogenic counterpart.

Mrs. R., aged 64; father died at the age of 69 and mother at 64 from acute diseases unknown to the patient. She has a brother and sister who are both living and well. She is married, has had 13 children and with the exception of a severe attack of pneumonia in 1894 has always been strong and well. The present illness began about July 1 when she was taken with a severe attack of nosebleed which was not fully controlled until two days. On July 12 she was up and about, but complained of a tired feeling and lassitude. She had lost some weight and always complained of shortness of breath. At that time she was somewhat anemic, had a blood pressure of 118 millimeters and had a soft blowing systolic heart murmur. Her pulse was 80, of fair quality. Her temperature was not taken. On July 15 she was again seen and again suffered from severe nosebleed, which required to be tamponed and did not entirely cease until about July 20. At that time her temperature was 101°, her pulse 90, respiration 20. The lungs were negative, heart negative except for slight systolic murmur, spleen slightly enlarged but not palpable, liver slightly enlarged, abdomen soft and tympanitic. During the first two weeks of her illness the bowels functioned normally but later obstinate constipation developed. Here it may be stated that during the whole course of the illness the patient ran a temperature which varied between 99.5° and 102°. The temperature was continuous and characterized by slight, if any, morning remissions. About July 23 small hemorrhagic areas developed on the upper lip and on the under surface of the chin and there also developed small hemorrhages into the subcutaneous tissue of the orbits which gradually increased until both eyes were surrounded by dark blue hemorrhagic areas. Throughout the whole course of the disease the patient was somewhat listless and apathetic, but was not delirious and retained consciousness until a very few minutes before death. There was very slight enlargement of the inguinal glands. At different times during her illness she complained of a sore throat which was reddened and congested. She developed sordes on the lips and tongue and at times developed slight hemorrhages from the gums.

This clinical history beginning with nosebleed, fever, and malaise naturally suggested the probability that we were dealing with typhoid fever, so about this time a Widal was done which proved negative. Early in August the hemorrhages all ceased and the ecchymoses began to be absorbed, but the fever continued and the patient very gradually lost in strength and vitality. On August 5 the Widal was again repeated and was again negative and a complete blood examination was made with the following results: Hemoglobin, 40 per cent.; red cells, 2,480,000; leucoctyes, 64,000; color index, 8.8. Differential count of 200 white cells showed

FIG. 1.—Mrs. R., 6 hours before death, showing remains of orbital hemorrhage.

the following proportions: Polynuclear neutrophiles, 20 per cent.; transitionals, 8 per cent.; lymphocytes, 7 per cent.; large mononuclears, 23 per cent.; myelocytes, 42 per cent. During the count an occasional nucleated red cell was seen and there was a moderate degree of poikilocytosis.

On August 6 blood cultures were made from blood removed from the median vein with a 10 c.c. syringe. From all inoculations made with this blood Gram positive non-pigment-forming staplylococci were isolated in pure culture. Another blood examination on August 7 gave findings identical with the one just reported except that the leucocytes had increased to 70,000.

The urine was scanty, acid in reaction had a specific gravity of 1.022, contained a slight trace of albumin, a great excess of indican, and the sediment showed a few hyalin and finely granular casts.

The patient gradually weakened, the heart's action became more rapid, and she finally succumbed on August 8. A partial autopsy was allowed which was performed that evening. The body was that of a fairly well developed, poorly nourished woman of apparently 60 years of age. The remains of the hemorrhages were seen about the eyes and upon the upper lip. Rigor mortis was slightly developed. There were no hemorrhages in the peritoneum and nothing of importance was noted except that the liver was somewhat enlarged, and anemic and the cross section showed indistinct markings and a condition of cloudy swelling of the organ.

The spleen weighed 267 grams and was 10 by 5 by 2½ centimeters in its dimensions. The surface was smooth, of a deep brownish red color and showed a few small areas of perisplenitis. The splenic tissue was very friable and tore under the slightest pressure. On cross-section it was seen that the tissue was very succulent and the pulp was easily expressed from the surface and smears were made which showed many large mononuclear cells with granulars which stained some with the acid and some with the neutrophilic stains. The trabeculæ and Malpighian bodies were distinguished with difficulty.

The kidneys showed senile changes and also a moderate degree of cloudy swelling. Paraffin sections were made of these organs and are now being studied. It is to be regretted that the marrow of the long bones could not be examined.

Bouillon cultures were made of the staphylococcus and guinea pigs and rabbits were injected, but it was apparently non-pathogenic and produced no symptoms except that in the rabbits the leucocyte count was raised from 3,200 to 18,000 and 20,000.

Conclusion.—We are dealing with a case of myelogenous leucemia ushered in by nosebleed about July 1, running a course, at least highly suggestive of an acute infection, and terminating in death about 39 days after the onset.

In regard to the blood cultures, we believe that contamination with the common *Staphylococcus albus* may be ruled out because of a most careful technique because of the isolation of the same organism in four separate inoculations and because the colonies of this organism are colorless, not white. We then are dealing with either an intercurrent infection, a terminal infection or an infection which is of etiological importance. We believe that a discussion of this question at this time would be of little weight or value and wish merely to state that the disease has all the earmarks of an acute infection and to say that in 1907 Zeigler and Jochman (*Deutsche medizinische Wochenschrift*) reported a case in which staphylococci were isolated from the pericardial cavity after a severe hemorrhage.

We believe that a careful blood examination in cases of apparent typhoid fever which have failed to give a positive Widal, will bring to light more of these interesting and obscure cases, and that blood cultures taken early in the course of the disease will clearly show its bacterial origin, and reveal the presence of an organism of low grade virulence, possibly identical with the one that we have mentioned, that has gained entrance to the red bone marrow or other hematapoietic tissue and there developed a type of sepsis which manifests itself in the symptom complex known as acute myelogenous leucemia.

THE LOAD OUR STUDENTS BEAR.

By WILLIAM F. WAUGH, M.D.,

CHICAGO.

EMERITUS DEAN, BENNETT MEDICAL COLLEGE.

SOME time ago the Coroner of Philadelphia, investigating the death of a student at the University of Pennsylvania, made the startling assertion that three-fourths of the class at that institution were in the habit of taking stimulants to enable them to fulfil the tasks imposed upon them by the course required. Coming from an official source like that, the statement demands consideration. If any appreciable proportion of our students are forced into drug habits by the severity of the strain laid upon them, it is time to call a halt on the increase of the requirements.

Bennett Medical College is distinctly a "poor man's school." Of 443 students in one year, about two-fifths work during term time to earn their expenses; in addition to attending college for an average of 44 hours a week, and such study as they may do outside of school hours. These men work in the post office, express, railway, pharmacy, and many other places—wherever a few dollars are to be earned during the hours not devoted to their classes. Certainly, if any medical students feel the strain it should be these men.

I wrote to every member of the class graduating last year, requesting information concerning their own cases and that of their classmates. These men had completed their courses and received their diplomas. They had no reason to refuse the information asked, and every reason to tell the truth. As far as possible I have counter-checked their statements by the evidence of each concerning the others. I believe, therefore, that the data here given may be considered trustworthy.

No. 1.—Besides college class work studied 25 hours a week; worked 12 hours a week. Total 82 hours a week, or about 12 hours a day. Effect on health rather bad. Used no stimulants except a little nux, iron, and gentian, when anemic. Only a strong constitution could endure it.

2.—Worked 58½ hours a week; making with school duties 18 hours a day. Tried alcohol to keep away sleep but failed. Tobacco did better. Coffee answered the need. During last 3 years took tonics and cannabin gr. 1/10 thrice daily, increasing during examinations. Supported wife and two children. "Most positively could not have done this without stimulation."

3.—Studied 27 hours a week; did well by keeping bowels regular and resting on Sundays. Those who studied on Sundays, or used alcohol and tobacco, did not do as well as others. This man did not work during his last two years.

4.—Worked none during school time. Studied five hours a day. Perfect health; needed and took no drugs. Some did take drugs, more from habit than necessity.

5.—Used no stimulants.

6.—Studied four hours a day. Worked two hours a day. Health not injured. Some others used strychnine and alcohol during examinations.

7.—Studied and worked four hours a day each. Used no stimulants.

8.—Used no stimulants but took good care of health. "Four long years of hard study besides the work one has to do outside of the school are certainly enough to shake the health of any robust student."

9.—Studied five hours a day outside school; did not work. Developed indigestion from over-eating and lack of exercise; also iritis from over-work. Nursed a sick mother. Took no stimulants but a two-mile walk daily.

10.—Studied three hours a day; did not work. Took no stimulants. No ill effect except nervousness.

11.—Worked 8 hours a day, studying at odd moments. No stimulants. Health now poor, having lost 17 pounds weight in last year. Smokes after meals. Supports family. Did not pass finals, from inability to learn when exhausted by work and lack of sleep.

12.—Studied four hours a week-day. No work. Gained weight and was never in better health. Used no stimulants, but drank beer and wine as ac-

customed to before and since school years.

13.—Studied three hours a day. Devoted 2½ hours a week-day and four hours Sunday to business. Grew thin but remained well. Used only tobacco regularly; occasional beer. While it is a hard game to work and study, men who used stimulants did so from habit or choice, strain being a mere excuse. "School work doesn't worry these except at examinations." Very few real workers use anything, or suffer in health.

14.—"Should the requisites be more exacting many of us would be obliged to resort to stimulants to keep up; or acquire some magic force or power to make good." Use coffee daily as a habit. Occasional beer or wine relished. Never used either, or any drug, as a stimulant. Stopped when limit of endurance was reached. Working students do not do themselves justice.

15.—Did no work; averaged four hours a day studying. Used no stimulants.

16.—Studied three hours a day, more near end of term. Did no work. Used no stimulants. Cared for health. One other student used caffeine.

17.—Used no stimulants. Studied five hours a day. Quite a number of students used strychnine, caffeine, and alcohol.

18.—"The medical course is too strenuous and I would not repeat it for a quarter section of land each year." Studied four hours a day. Worked three hours a day. Unfitted for work much of the time. Used strychnine and other tonics; wife says he lived on stimulants but this he denies. Shunned alcohol but used malt. Took camphor to induce sleep. Others used strychnine.

19.—Studied three hours a day. Worked three hours a day. Was nerve-racking, and still feels the evil effects. Took no stimulants. Some use strychnine—among the best in the class.

20.—Studied four hours a day. Did little work outside. During third year suffered sense of high vascular tension after two hours' study, with mental disability and headache. Is now well as when he entered college. Took coffee for dizziness when studying more than two hours. Lost much health during course. This was a foreigner who had difficulty with his English.

21.—Studied three hours a day; worked six hours but did some study during these; the college course did not injure health, finished in excellent condition and remains well; had plenty of exercise, but could not regulate quantity or quality of food, both which were at times deficient; used no stimulants, did not need them; not even tea or coffee as a habit; alcohol did not stimulate but hindered.

22.—Studied twelve hours a week; used no stimulants of any kind to aid in work; did little outside work; health not affected—gained weight.

23.—Did no study, his previous attainments being so great as to render it unnecessary; but reviewed the week's work each Sunday; worked in shop every evening until midnight, supporting wife and child; no effect upon health; used no stimulants to aid study, but smoked.

24.—Studied seven hours a day; worked six hours a day for first semester, but not after holidays; weight dropped from 118 to 102; used stimulants and narcotics, mainly coffee with occasional alcohol; it is not the work that hurts but the worry.

25.—Used no narcotics, but strychnine and caffeine to keep awake all night during examinations; worked from 5.30 to 11 P.M., studied till 2 A.M., slept from 2 to 7 A.M., became neurasthenic and hypochondriac, lost 40 pounds weight, had appendectomy, and three other operations; but has regained health since graduation.

26.—Studied six hours a day; did little work; closed college course with health improved; used no tobacco, alcohol or other drugs; his stimulant a cold bath; vegetarian, eating meat once a week.

27.—There were no drug addicts in the class; tobacco and alcohol used by majority; studied two and one-half hours daily; health better at end of senior year than at beginning of freshman; used dumbbells and cold showers; did no outside work; used tobacco regularly and alcohol occasionally, the latter in sophomore and last semester of senior years; passed State Board with record of over 88 per cent.

28.—Studied 2 to 3 hours; worked 4 to 5 hours daily; effect on health fair; used no stimulants beyond several cups coffee daily, no alcohol, very little tobacco, slept well.

29.—Studied four hours daily; during senior year served as extern, rarely having a night undisturbed; operated on for appendectomy when senior, effect on health doubtful—gained 15 pounds since graduation; never used stimulants or narcotics or even thought of using them during course.

30.—Used no stimulants or narcotics, not even coffee or tobacco; did little outside work during last year, but did some in the other years; "Eight hours' note-taking after lecturers daily, taxed physical being to the extreme limit."

31.—Worked outside school from 4 to 12 P.M., besides two to three hours' daily study; health good but lost 12 pounds weight; used no stimulants except a rare glass of beer. Passed state board before graduation, in two states.

32.—Studied one hour a day outside classes and put in all spare time days and evenings in the hospital; effect on health good; used no stimulants, smoked some.

33.—Studied 2 to 3 hours a day outside college; worked 3 to 4 hours a day; used alcohol moderately, tobacco to excess; did not study Sundays; in no way affected health.

34.—Studied 5 hours daily; did no work; no ill effects; used no stimulants or hypnotics. This was a colored man who passed his examinations with credit in Jamaica and in Massachusetts.

35.—Used no drugs except tobacco and an occasional beer; and hot coffee to keep away sleep; studied 35 hours a week but thinks the average student cannot bear more than 20 hours; when students made a poor showing they and not the curriculum were at fault. This man attended his first and second years at a night school; he passed before the Illinois Board the best examination of the last five years, stood nineteenth in the Cook County Hospital competition held exclusively by examiners from one of the competing colleges, and secured immediately a lucrative hospital appointment.

36.—Studied five hours a day; not including Sundays; spent no time at supportive work; no bad effect on health, but took exercise, never crowded digestion, kept bowels regular and slept well; too many students lost out by crowding brains; took no stimulants but went to bed when overcome by sleep, studying in early morning; once or twice in freshman year took caffeine citrate gr. ½, but it did not answer.

37.—Studied eight hours a week outside class; worked four hours a day; no bad effect on health;

used no drugs, cut out smoking the three months before end of term.

38.—Had to work so hard in junior year that near its end had to take several cups strong coffee to keep awake at nights; for a month also took phosphorus; studied 25 hours a week; 42 hours' work weekly; at end of third year became nervous, memory and thought became difficult; smoked often, to 10 cigarettes a day, seldom drank except on a holiday a glass of wine.

39.—Studied 5 to 6 hours seven days a week; did no work for money; no harm to health; never had to use stimulants—the course was never so heavy as to compel him to extend himself very much; same as to drugs.

40.—Studied little because had to work every hour possible outside college classes; used no stimulants or narcotics; health always good. This man barely passed his finals.

41.—Studied 10 hours a day; did no manual work; used no stimulants, litttle tobacco; lost 10 pounds weight, but suffered no real injury to health.

42.—During first and second years worked average of four hours a day; studied three hours a day, smoked as usual five cigars a day; third and fourth years studied 30 to 40 hours a week, smoked as usual, had good health except some eye-strain; gained weight 10 pounds; used no stimulants; suffered in examinations from nervousness; health good now.

43.—Studied three hours a day. Did janitor work 5½ hours a day. Kept awake by walking. Never lost a day from school. Used nothing; never tasted alcohol.

44.—Studied four to five hours a day outside college; worked six hours a day besides; no ill effect on health because of a very strong constitution; no stimulants except cigars seven a day and coffee three cups a day.

45.—Studied two hours a day; worked six hours a day; lost 26 pounds weight; used no stimulants or tobacco.

46.—Studied three hours a day; did not work; health broke down from bad sanitation as well as overwork; used no stimulants.

47.—Studied three hours a day excepting Sunday; worked six hours a day including Sunday; earning thus entire expenses of college course; as well as four-year high school; health at graduation fairly good, due to active outside work; without which health would have given way; used no stimulants except a cup of strong coffee or chocolate just before going in for examinations.

48.—Studied an hour occasionally; did no other work; perfect health during entire four years at Bennett; occasional cigar or beer, used no stimulants or tonics, drank coffee at breakfast, because always in a hurry, and did not always have price of a breakfast. The average student could cover the course in less than four years and do it better.

From several men I have been unable to obtain a direct reply. Of each of these I have secured data from room-mates or intimate friends, and I am sure that not one of them used alcohol or drugs habitually during his term. Nevertheless, as some may not trust this indirect evidence I state the facts of the matter.

It is evident that the personal equation must be applied, rather than any generalization based on averages. Probably the most significant reply is that given as No. 47. This man gave 18 hours a week to study, and 42 hours to productive work, yet finished in good health and even attributed this to his outside work. Note that he did no study on Sunday, and this stands for a moral life as well, which has not been without its influence. Such men are not likely to dissipate their energies in other ways.

Nevertheless, the showing is not a good one for the workers, more than half complaining of the strain. This goes to confirm the views of those who claim that the student should not try to do productive work while studying medicine. I regret this, for the students of this class have as a rule approved themselves of superior quality. The man who works to earn his education does better and is of better stuff than the one whose relatives pay his expenses through college. But—truth is truth, and I present the evidence as it comes to me from the students themselves.

The man who attempts to earn his living while attending the modern medical school, should lay down his campaign as carefully as the modern general does, and calculate his own powers, the means of keeping his body in the best condition and the extent of his own working capacities without undue strain. In a word, he must be a qualified sanitarian and successfully apply the laws of sanitary science to his own case.

Beyond this, the same duty accrues to the school. I have had to advise intending nurses to avoid one at least of the Chicago nursing schools, because the students broke down from overwork and bad hygiene before the completion of their course, and presented themselves at graduation in a condition of physical exhaustion that reflected anything but credit upon the institution.

Questioning the head of the school upon this, the only satisfaction received was that "this was a matter the nurse should have seen to before she undertook the course." Believing that this was not the spirit that should be inculcated in the nurse, and that there was evident a lack of capacity for comprehending or teaching the necessary duties of the profession, I had to advise prospective nurses against that school.

A medical college that allows its students to work during term time must look after the health of these men and see that it does not suffer. It need not; but it is up to the college to see that it does not suffer.

A CASE OF RETROPERITONEAL AND EXTENSIVE SUBCUTANEOUS EMPHYSEMA FOLLOWING INTRATRACHEAL ANESTHESIA, WITH RECOVERY.

BY SIMON D. EHRLICH, M.D.,

NEW YORK

ANESTHETIST [illegible] BETH ISRAEL AND JEWISH MATERNITY HOSPITALS.

THE writer desires to place on record the following case which is one of unusual interest:

Celia B., aged 31, was admitted to the Beth Israel Hospital February 5, 1913. She was kept under observation until April 2, 1913, when she was operated on by Dr. Charles Goodman for intermittent pyonephrosis due to obstruction of the ureter. On examination of the patient, before anesthesia, the general condition was found to be good; heart and lungs normal, temperature normal, pulse 88, respirations 24. The patient was easily anesthetized by gas, oxygen, and ether, a Coburn inhaler being used. She was then easily intubated with an ordinary soft sterile rubber catheter, 22 Fr., introduced by means of the Cotton introducer. The catheter was then connected with the

Elsberg intratracheal apparatus and the anesthesia continued with a pressure of 20 mm. Hg. and an ether index of 30. Color, respiration, and pulse were good. The operation was then begun, the first part being an exploration of the kidney through the usual lumbar incision, the patient being placed on her stomach. (I wish to remark that since the advent of intratracheal anesthesia, we have been using this method to distinct advantage for all kidney operations where the patient is placed flat on the stomach and the breathing is embarrassed, making the ordinary methods of anesthesia difficult and unsatisfactory.) The kidney was delivered and incised. It was then found impractical to continue the operation in this position. The kidney was then sutured and replaced, and the wound closed. The patient was then turned over and the abdomen was opened on the right side and a transplantation of the ureter above the point of obstruction was made into the bladder. The first part of the operation took about thirty minutes. The anesthesia progressed smoothly: breathing and color were good. Soon after opening the abdomen and the search for the ureter begun, a marked emphysema of the retroperitoneal space was noticed. There was no change in the appearance of the face or neck. The general condition was good. The operation progressed and the anesthesia was continued. It was only at the close of the operation, about forty-five minutes after the appearance of the subperitoneal emphysema, that the swelling of the face with the characteristic crackling of emphysema was noticed. This soon spread, involving the entire face, neck, and chest. The anesthesia, which had lasted one and a half hours, was discontinued. General condition was good: color, respiration, and pulse were satisfactory. April 3, the day following the operation, emphysema of the face and neck was somewhat less marked. April 4, still less. April 5, it had diminished considerably, and the patient's general condition was very much better; the abdominal distention from which she had been suffering was relieved. The emphysema diminished rapidly, so that on April 8, six days after the onset, it had completely disappeared. The pulse rate on the days following the operation ranged between 88 and 100, respirations between 22 and 28. The patient was never cyanosed, the breathing was not labored, and there were no signs of laryngitis or bronchitis. The patient's wound closed by primary union. Her general condition was good and continued so, until her discharge from the hospital on May 6, 1913.

In explanation of this condition the only possible cause that I can see is a slight abrasion of the pharynx or larynx, due to the introduction of the catheter. I do not believe that we can consider here the possibility of overdistention of a bronchus and rupture of the lung, this being the probable etiological factor in Luke's[1] cases, because we had here an instrument which was under constant control, a safety valve in action, with pressure never above 25 mm., and the catheter not being down far enough to have entered a bronchus. The extensive retroperitoneal emphysema is explained by the entrance of air through the abrasion in the pharynx or larynx into the posterior mediastinum and from here along the spinal column to the retroperitoneal space. This condition is very rare. I have not been able to find a single reference to it in the literature. There is a report by Carl Herrman Dischler[2] of subperitoneal emphysemas following rupture of the uterus during labor. In these cases the air was found in the anterior wall of the abdomen in the hypogastric space. I suppose there have been instances of air in the retroperitoneal space, but these remained unnoticed because laparotomies were not performed. In our case recognition was simple, because the abdomen was open.

To those who may object to the method of intubation used, I wish to state that I have been using it for two years, and find it much more simple and satisfactory than the introduction by Jackson's direct vision laryngoscope. Contrary to the Jackson method, in the use of the Cotton introducer, the patient does not have to be moved over the edge of the table, there are no interruptions due to the burning out of lamps; the handling of the introducer is much more easily mastered. After all, why should it not be possible to introduce a catheter into the larynx, by means of the sense of touch, as easily as is constantly done with tubes in intubation? I have had difficulty with the introducer in a few cases and I found the cause to be a rather small pharyngeal orifice which did not allow the catheter to be brought to the larynx on account of the large curve of the Cotton introducer. I had Tiemann & Company make an introducer for me, with a smaller and somewhat differently shaped curve which I find overcomes this difficulty. One of the principal reasons for the use of the Jackson method of introduction was that one could be absolutely certain that the catheter was introduced into the larynx. In spite of this there have been numerous instances of pharyngeal introduction and anesthesia as is mentioned by Meltzer[3] in his recent article on how far the catheter should be inserted into the larynx. He there speaks of the fact that one must introduce the catheter up to the point where one meets with an obstruction, showing that it has entered a bronchus. This is done to make certain that the catheter is in the larynx, and not in the esophagus, which proves that by this method, even by direct vision, one cannot tell absolutely whether the catheter is in the trachea. With the ordinary introducer, however, it is always possible to make sure with the index finger of the left hand, which is in the throat as a guide to the introducer, as it is used in intubation, whether the catheter is really in the trachea.

In closing, I wish to state that, in spite of the possibility of this accident of subcutaneous emphysema occurring, which is after all very infrequent, this being the third case reported, I believe that, with the proper use of a safety valve, this form of anesthesia is the safest and most convenient we have to-day in operations on the head and neck, in those within the thorax, and those requiring positions which embarrass respiration.

Medicolegal Notes.

Application for Charter—Legal Status of Applicants. In an application for a charter for a corporation of the first class, to be known as the "Chiropractors' Association of Pennsylvania," it appeared that the applicants were engaged in general practice in the treatment of diseases, but that they had no legal status as medical practitioners. It was held not an abuse of discretion of the court below to withhold approval of the application until they had attained such status under the laws governing medical practitioners.—Appeal of Chiropractors' Assn. of Pennsylvania, Pennsylvania Supreme Court, 90 Atl. 335.

Hypothetical Questions—Basis.—A physician's opinion that the plaintiff's condition was the result of an injury received by her in a specified accident was held to be incompetent where it was based in part upon a physical examination, in part upon the history of the case as related to him by the plaintiff, and in part upon what the plaintiff's attending physician had told him in a consultation.—Beattie vs. J. L. Hudson Co., Michigan Supreme Court, 146 N. W. 650.

CEREBROSPINAL FLUID.

SINCE the introduction of lumbar puncture by Quincke in 1891 a great amount of information has been accumulated concerning the composition of the cerebrospinal fluid under both normal and pathological conditions. The investigation of this fluid has become a matter of importance in the diagnosis of many diseases, and the method of lumbar puncture is used for the administration of a number of therapeutic agents. In all this time the knowledge of the physiology of this secretion has advanced very slowly. Theories have been many but few of them have found confirmatory facts to support them. In this accumulation of fact and fancy the work which has recently appeared (*Journal of Medical Research*, September, 1914) by Cushing, Weed, and Wegefarth, stands out as the most important contribution to the physiology and pathology of the subject since Quincke's revolutionary announcement. The source of the cerebrospinal fluid has for a comparatively long time been believed to exist chiefly in the choroid plexus, and since the work of His, some investigators have considered the so-called perivascular lymph spaces as an accessory source. No direct proof, however, has been offered to support these theories. These workers introduced a silk catheter through a slit in the exposed occipito-atlantoid ligament, through the aqueduct of Sylvius into the third ventricle. From the opening of this catheter fluid dropped which was exactly similar to cerebrospinal fluid, and continued to drop for some time. This experiment thus affords direct evidence that fluid is secreted by the choroid plexus, since the lining ependyma of the ventricle fails to yield any histological evidence of secretory activity. It also has afforded an excellent opportunity to study the effect of drugs upon the secretion of cerebrospinal fluid and it was found that the secretion was stimulated by ether, pilocarpine, choroid extract, and the secretion of the posterior lobe of the hypophysis. By means of their injection experiments they were able to demonstrate a direct connection between the subarachnoid space and the perivascular spaces. It is noteworthy that the injection of these spaces was satisfactory only when an anemia of the brain was created during the course of the injection. Thus there is demonstrated a dual source for the fluid, the chief one through the choroid plexus and the accessory one from the perivascular spaces. They believe it is over the latter path that the brain cells rid themselves of waste products. In addition they draw the analogy to the dual source, from the ciliary body and from the retina, of the aqueous humor of the eye.

In their studies they tried out many methods of injection and finally determined the superiority of the injection of a solution of potassium ferrocyanide and iron and ammonium citrate in such strengths that the solution was practically isotonic. This was injected very slowly at a pressure only slightly above that of the spinal fluid normally. At the end of the injection the animal was killed and the head fixed in formalin containing hydrochloric acid. This treatment resulted in a precipitate of Prussian blue in all places reached by the injected solution. The results obtained by this method far exceeded those hitherto thought possible. The authors were able to show conclusively that the fluid escaped from the ventricles into the subarachnoid space and thence found its way into the sinuses of the dura through special processes of the arachnoid, the arachnoidal villi, which project directly into the sinuses. These villi are delicate web-like structures which continue the outer arachnoid membrane into the dural wall. They have not hitherto been described at all adequately, especially in this connection, although anatomists have always been familiar with the pathological form of the villus, the Pacchionian granulations. There exists also an accessory pathway of absorption through the perineural spaces around the cranial and spinal nerves from which the fluid is taken up by the lymphatics. Here, again, these authors have demonstrated a remarkable analogy between the cerebrospinal fluid and the aqueous humor of the eye. The principal pathway in the eye is through the spaces of Fontana and the pectinate ligament and into the canal of Schlemm by means of the pectinate villi which are wholly similar to the arachnoidal villi. The accessory pathway here is apparently by way of the perineural space about the optic nerve, which furnishes a direct connection between the subarachnoid space and the interior of the eye. They also point out the close chemical similarity of the two fluids.

These studies are exceedingly enlightening and open wide and attractive fields for research and speculation. It will take years to realize to the full their possibilities of practical application. It was the good fortune of these workers, however, to obtain a naturally hydrocephalic kitten and by pushing a hollow needle through the superior longitudinal sinus into the subarachnoid space they were able to create a direct connection between the two. This remained open for at least a week and the operation was repeated several times. Each time the symptoms were relieved for about a week and there were apparently no unpleasant sequelæ. In this connection they were able also to demonstrate that the pressure of the cerebrospinal fluid was greater than that of the blood in the dural sinuses. Further experimentation along the lines suggested by this work will no doubt yield information of tremendous therapeutic value. The authors state that they are investigating the effect of drugs on

the rate of secretion of the cerebrospinal fluid and there are many other important questions which are probably susceptible of solution by these methods.

FIBRINOLYSIS AND HEPATIC INSUFFICIENCY.

It was Dastre who in 1893 applied the term "fibrinolysis" to connote the dissolving of fibrin in the blood serum. This process is manifested to a small extent under normal conditions, whipped fibrin losing eight per cent. of its weight in eighteen hours. But if a clot is incubated at body temperature in a sterile serum, it can be kept for many weeks without undergoing complete dissolution.

These facts are pointed out by E. W. Goodpasture (*Johns Hopkins Hospital Bulletin*, November, 1914) who has made a special study of the increased fibrinolysis of the blood serum occurring in association with chronic hepatic insufficiency. This study was suggested by the observation that the clot forming in the blood removed from the heart of a patient that had died from advanced cirrhosis of the liver completely dissolved in the course of three and one-half hours.

Jacoby in 1900 observed a greatly increased fibrinolysis of the blood serum in experimental phosphorus poisoning in the dog. Later Wolf reported the same sequence in dogs that had received intravenous injections of proteoses or in animals subjected to extirpation of the liver. There was ample evidence to support the view that fibrinolysis is the result of enzyme action, two possibilities suggesting themselves in explanation of the increased fibrinolysis occurring under pathological conditions, namely, an increase in the proteolytic ferment over an antiproteolytic ferment, or a diminution in or an absence of the latter permitting the proteolytic ferment to go on unchecked.

Goodpasture has made the first definite observation of increased fibrinolysis as a phenomenon accompanying pathological conditions, for he reports a series of four cases of atrophic cirrhosis of the liver in which the process of fibrinolysis was so active that the blood dissolved its own clot within a few hours at body temperature. He also proves that fibrinolysis is the result of enzyme activity, for the process is destroyed by the temperature of 65° C., inhibited by normal serum, and diminished in the presence of old plasma. On the basis of all available data Goodpasture concludes that increased fibrinolysis is the result of a diminution in or an absence of normal antiproteolytic substances.

In all of the author's cases there was a hemorrhagic tendency. The association with atrophic cirrhosis of the liver suggests a close analogy with the cases of hepatic injury resulting from phosphorus poisoning. The tendency to hemorrhage in cases of insufficiency of the liver cells can now be easily explained as resulting perhaps from a rapid dissolution of the clots that under normal conditions act as Nature's hemostatic. Although in these cases the fibrinogen content was below normal, it was not so far below normal as by itself sufficiently to predispose to bleeding.

The demonstration of active fibrinolysis in cases of advanced hepatic insufficiency therefore becomes a sign of eminently practical value in diagnosis and prognosis: first, as a means of differentiating those cases of obscure ascites in which one may be uncertain as to whether the heart or the liver may be at fault; and second, as a means of determining whether the hepatic impairment is in an early or a late stage.

ANTITYPHOID INOCULATION.

Facts as to the efficacy of antityphoid inoculation accumulate almost daily. Perhaps the most satisfactory statistics with regard to the value of the method are those afforded by the United States Army. As pointed out by Mayor Russell of the Medical Corps, U. S. Army, in 1911, it was made compulsory for all recruits in the army. The following figures showed the contrast between the state of affairs in the Spanish War and that in 1911. At Jacksonville, Fla., in the earlier campaign there occurred certainly 1,729 and probably 2,673 cases of typhoid fever with 248 deaths. The strength of the force was 10,579. At San Antonio when an American army was concentrated on the Mexican border in 1911, 13,000 men were encamped for about the same length of time as in the Spanish War and among these there were only two cases of enteric fever and no deaths, though the disease was actually present in the civil population of San Antonio and the troops were allowed to enter the town freely. According to Major Russell, in the army as a whole a great drop has occurred in the incidence of typhoid fever since inoculation was made compulsory. Reports from France are as favorable as those from this country. For example, during an epidemic of typhoid fever in Avignon, the garrison of the town consisted of 2,053 men, of whom 1,366 were inoculated. Among the unvaccinated soldiers 155 cases of typhoid fever with 21 deaths occurred, while among the vaccinated there was not a single case. All the soldiers lived under exactly the same conditions. Again, in Eastern Morocco among 962 vaccinated soldiers there was no case of infection, whereas among the nonvaccinated the morbidity was 38.22 and the mortality 5.51 per 1,000.

In the British Army in India the results of the method have been conspicuously brilliant. There the typhoid rate fell in five years from over 15 to under 5 per 1,000, and the death rate from over 3 to 0.63 per 1,000. During the year 1910 among about 70,000 men there was a total of 306 cases of enteric fever; 151 of these occurred in the 10,000 who were unprotected and only 155 in the 60,000 who had been vaccinated. Only 11.2 per cent. of the inoculated died and 16.1 per cent. of the uninoculated. It must be borne in mind that members of the white race in India are peculiarly prone to typhoid fever and that up to recent years this has been one of the main causes of sickness and death.

Figures dealing with the efficacy of antityphoid inoculation in the Italian and Japanese armies tend to show that the method has greatly decreased the death rate and morbidity rate from this cause. The Italian statistics are especially favorable, while the

heads of the Japanese Army have found antityphoid inoculation of so great preventive value that it has been made compulsory.

At the present juncture, the question is insistently of moment. Immense masses of men are gathered together in Europe under conditions necessarily the reverse of sanitary. In spite of all precautions typhoid fever is certain to break out, in fact, has already broken out. Consequently, any method calculated to protect individuals from contracting the disease should be employed without hesitation. Even if the method had not been proved to be as efficacious as it certainly is it should be practised. When an authority of the rank of Sir William Leishman declares that not only is antityphoid vaccination efficacious but the subsequent ill effects are slight and fleeting, a view which is endorsed by the great majority of the British medical profession, and when Professor Chantemesse of Paris goes so far as to state active belief that typhoid fever will gradually disappear during the present century just as smallpox vanished in the nineteenth century and when Italian and Japanese authorities, who have tested the method, are practically unanimous in giving evidence as to its value, scepticism must, to a great extent, vanish.

POLLUTION OF THE GREAT LAKES.

THE Progress Report of the International Joint Commission of the United States and Canada with regard to the pollution of the boundary waters of the Great Lakes, has been published recently. The publication is one of much value as it records the work of experts, so far as it has gone, in discovering the effect of sewage pollution, more especially of cities bordering on the lakes, on the health of the community and particularly with respect to the dissemination of typhoid fever. In Bulletin No. 77, prepared by Dr. Allan J. McLaughlin and issued by the U. S. Public Health Service, the extent of sewage pollution of the Niagara River and the danger to the public health were shown.

Attention has been drawn on several occasions to the menace of Niagara to the public health. Niagara City has long been somewhat notorious as a place in which typhoid fever is more prevalent than is fitting, and it seems obvious that just so long as the city of Buffalo, situated at the head of the Niagara River, is permitted to discharge all its sewage untreated into the river above the intakes of the public water supplies, will the Niagara River be a source of danger to those dwelling along its banks. Buffalo is not the only guilty community, for there are also several Canadian municipalities on the river and the sewage from these is discharged into the river untreated. The problem of how best to deal with the sewage of Buffalo, as also that of the other towns on the Niagara River, is being considered, and it is anticipated that in the not far distant future all the communities abutting on the famous river will deal with their water supply in a manner in keeping with modern methods and in the interests of public health.

The second factor in point of importance is the discharge of sewage by vessels. Not only do vessels contribute their quota to the sewage pollution of these waterways, but they menace the public health in other ways. Vessels are supposed to fill their drinking water tanks from mid-lake, remote from sources of pollution. But they frequently neglect to do this and obtain their drinking water from polluted sources.

It goes without saying that the effect of pollution of the lake waters on public health shows itself principally in the form of typhoid fever. Statistics demonstrate that several of the lake cities have a mortality from the disease which would not be tolerated for one moment in the large cities of Northern Europe, and this, moreover, where the conditions relating to filth and poverty are more obvious by far. In the past three years the death rate per 100,000 from enteric fever in Niagara Falls, N. Y., was 196; in Port Arthur, Ont., 179, and 330 in Sault Ste. Marie, Ont. Even in those large and prosperous cities in which it might be imagined that no trouble or money would be spared to ensure an uncontaminated water supply, the typhoid death rates are such as would shock a British or German public health authority.

However, the appointment of the International Commission on the Pollution of the Great Lakes is a step in the right direction, and it is to be hoped that the result of their labors will act as incentive to those concerned in matters of the public health in every State of the Union.

ABDERHALDEN'S SEROREACTION AND X-RAYED ORGANS.

SINCE organs which have been persistently *x*-rayed undergo changes, due perhaps to activation of the tissue enzymes, the thought lies near that they may give up foreign substances to the blood which cause in the latter the production of defensive ferments. It is also not improbable that radiations of a given portion of the body are able to provide changes in certain remotely seated organs—as the genital glands, liver, and brain. The first experiments in this direction, however, have met with negative results. At the medical section of the Naturwissenschaft.-medizinische Gesellschaft of Jena last summer (*Münchener medizinische Wochenschrift*, September 29) Eden reported that he had subjected both men and animals to intensive radiation. The former comprised chiefly victims of surgical tuberculosis and malignant tumors. The Abderhalden reaction exhibited no form of behavior which could be attributed to any positive action from the rays. The human subjects had previously reacted in accordance with their diseases, and no further change occurred. The rayed dogs who were healthy before the experiments afterwards showed reaction evidence of disintegrated brain tissue, but this was attributed to the action of the narcotic.

News of the Week.

Civil Service Examinations.—A competitive examination will be held December 12, 1914, for superintendent, Tompkins County, N. Y., Tuberculosis Hospital, salary $1,200 and maintenance for the superintendent. An unmarried man is preferred for this position as the hospital has no ac-

commodations for the family of the superintendent. Preference will also be given to residents of New York State. This examination is open only to male physicians, who are licensed to practise medicine in New York State. Persons desiring to enter the examination must file applications on blank form E-10 in the office of the State Civil Service Commission on or before December 8, 1914.

An examination will also be held on the same date to fill the position of laboratory assistant, qualified in complement fixation work, State Department of Health. $720. Open to men and women. The duties of this position are to assist in the work of the laboratory and candidates should possess an elementary knowledge of bacteriology and immunity, together with practical experience in the tests used in serum diagnosis, such as complement fixation or Wassermann reaction and the agglutinative and bacteriolytic reactions.

New York City Death Rate.—The death rate in this city for the week ending November 21 was 11.92 per thousand, during the corresponding week last year it was 12.14, the decrease being equivalent to a saving of twenty-four lives. During this year up to the present there has been a decrease of three-tenths of a point in the death rate, compared with the corresponding rate of 1913. The maintenance of this decrease to the end of the year will indicate a saving of 1,730 lives as compared with the mortality experience of 1913.

Against Fee Splitting.—At a meeting of the Medical Society of the County of Monroe, held in Rochester, October 20, a resolution was adopted "that the Society hereby expresses itself definitely as being vigorously opposed to this practice in any form whatsoever, that there is no justification of this practice even on economic grounds for it seems entirely improbable that there will grow up any adequate recognition of the value of purely diagnostic medical services, until this evil secret adjustment be abolished, and that a correct and sufficient fee for such services be openly and courageously charged in its stead."

Personal.—Dr. C. C. Bass of New Orleans has been awarded the medal of the Southern Medical Society for scientific research. This is the third year in succession that this medal has been given to Dr. Bass.

Dr. J. B. Carnett has been appointed surgeon to the Philadelphia General Hospital in succession to Dr. Edward Martin resigned.

The National Health Guard is the name of an association having for its object the promotion of public and individual health and to stimulate public interest in every wisely designed movement to prevent life-waste and upbuild national vitality. Those who enlist in this organization give the following pledge: "I will, in so far as my circumstances and opportunities will permit, make an earnest effort: (1) To inform myself upon the subject of personal, community, and household hygiene, and to myself obey the laws of health. (2) To encourage the practice of individuals having periodic health examinations to upbuild physical efficiency and to detect disease in time to check or cure it. (3) To give support and encouragement, and to urge my friends to do the same, to the public health service and officials who are laboring to protect the most precious asset of the nation. (4) To encourage schools, churches, social, and civic bodies and employers to give as a patriotic duty all consistent help in stimulating public interest in and in spreading knowledge of the rapidly advancing science of health and life conservation. (5) To cooperate with and advise the Life Extension Institute in its purpose to reduce life-waste and to guard and strengthen the vitality and vigor of our race."

Professor Rudolf Emmerich, chief of the department of bacteriology and hygiene in the Königliche Bayrische Ludwig-Maximilians-Universität, Munich, Germany, since 1902, died recently in his sixty-second year.

Harvey Society Lecture.—The fourth lecture of the tenth course of the Harvey Society will be delivered at the New York Academy of Medicine on the evening of Saturday, November 28, at 8:30, by Prof. Lafayette B. Mendel of Yale University. Subject: "Nutrition and Growth."

The Mutter Lecture, on "Surgical Pathology," will be delivered by Dr. F. H. Albee of New York City in the Thomson Hall of the College of Physicians of Philadelphia at 8 p. m., December 4, 1914. Subject: "The Fundamental Principles Involved in the Use of the Bone Graft in Surgery." After the lecture a reception will be given to Dr. Albee at the Hotel Rittenhouse.

Charitable Bequests.—In the will of the late William Endicott of Boston bequests are made of $25,000 for cancer research at Harvard University, $50,000 to the Beverly Hospital, $25,000 to the Massachusetts General Hospital, and $10,000 each to the Sharon Sanitarium, Y. M. C. A. and Instructive District Nursing Association of Boston.

The will of the late Jean Baptiste Guttin, a restaurant proprietor of this city, gives $4,000 to the French Hospital of New York.

By the will of the late Annie E. Matthews the sum of $5,000 is bequeathed to the Howard Hospital for the establishment and maintenance of a free bed in the name of Anna E. Ulmer to be dedicated to the use of female patients, and also the sum of $1,000 to the West Philadelphia Hospital for Women.

By the will of the late Jennie E. Disston the sum of $1,000 is bequeathed to the Germantown Hospital.

By the will of the late Emma L. Forrest the sum of $10,000 is bequeathed to the trustees of the University of Pennsylvania for the endowment of a room in the Agnew Pavilion of the University Hospital in memory of her husband, the late Dr. Morton H. Forrest.

Medical Society Elections.—The Southern Medical Association, at its eighth annual meeting in Richmond, Va., November 12-14, elected the following officers: *President*, Dr. Oscar Dowling of Shreveport, La.; *First Vice-President*, Dr. R. C. Dorr of Batesville, Ark.; *Second Vice-President*, Dr. McGuire Newton of Richmond, Va.; *Secretary*, Dr. Seale Harris of Mobile, Ala. The next meeting will be in Dallas, Texas.

The Southwesteern Medical Association held its ninth annual meeting in Galveston on November 10 and 11. The following officers were elected: *President*, Dr. J. D. Griffith, Kansas City; *First Vice-President*, Malvern B. Clopton, St. Louis; *Vice-President for Texas*, Dr. A. E. Sweatland, Nacogdoches; *Oklahoma*, Dr. T. H. Flescher, Shawnee; *Missouri*, Dr. Malvern M. Clopton, St. Louis; *Arkansas*, Dr. F. D. Holland, Jr., Fort Smith; *Kansas*, Dr. Ernest F. Day, Arkansas City; *Secretary-Treas-*

ver, Dr. Fred H. Clark, El Reno, Okla. The next annual meeting will be held in Oklahoma City.

The Georgia Sixth District Medical Society, meeting at Macon on November 11, elected the following officers: *President*, Dr. O. H. Weaver of Macon; *Vice-President*, Dr. Charles C. Harrold of Macon; *Secretary*, Dr. I. H. Adams of Macon. The Southern Illinois Medical Society elected the following officers at its annual meeting held in Mount Vernon on November 7: *President*, E. W. Lingle, Cobden; *Vice-Presidents*, Drs. T. H. D. Griffith, Springfield, and A. J. W. Armstrong, Centralia. The next meeting will be held in Harrisburg.

At the annual meeting of the Aid Association of the Philadelphia County Medical Society, held November 9, the following officers were elected for the ensuing year: *President*, Dr. Jacob R. Shellenberger; *Vice-President*, Dr. J. C. Wilson; *Secretary*, Dr. Lewis H. Adler, Jr.: *Treasurer*, Dr. John B. Turner; *Solicitor*, Francis C. Adler; *Directors*, Drs. James M. Anders, William M. Welch, J. Solis Cohen, Samuel D. Risley, Samuel W. Morton, Charles A. E. Codman, Isador P. Strittmatter, William S. Wray, and William T. Hamilton.

The following officers of the New York Division, Association of the Medical Reserve Corps, U. S Army, were elected November 14: *President*, Reynold W. Wilcox; *Vice-President*, Howard Fox; *Secretary*, Harold Hays; *Treasurer*, H. Sheridan Baketel; *Councillors*, Henry C. Coe, Herbert Lawson, Walter M. Brickner, S. Meredith Strong, Thomas Darlington, Frederick N. Wilson.

Obituary Notes.—Dr. ANDREW J. JACKSON of Matawan, N. J., a graduate of the Medical Department of the University of Buffalo, N. Y., in 1873, and a member of the American Medical Association, the Medical Society of New Jersey, and the Monmouth County Medical Society, died at his home on November 17, aged 72 years.

Dr. ANDREW SPRAGUE OLIVER of San José, Cal., a graduate of the Hahneman Medical College and Hospital, Philadelphia, in 1881, died at his home suddenly on November 8.

Dr. WILSON R. PRIEST of Concordia, Kan., a graduate of the Medical College of Ohio, Cincinnati, in 1886, and a member of the Kansas and Cloud County Medical Societies, died at his home, after a long illness, on November 9, aged 54 years.

Dr. AMOS DAVIS of Owensboro, Ky., a graduate of the Medical Department of the University of Louisville in 1874, and a member of the Kentucky State Medical Association and the Daviess County Medical Society, died at his home from Bright's disease, after a long illness, on November 10, aged 66 years.

Dr. EUGENE V. WEST of Tampa, Fla., a graduate of the Mebarry Medical College, Nashville, Tenn., in 1892, and in point of service the oldest neegro physician in the city, died at his home on November 5, aged 45 years.

Dr. AMOS H. FARISH of Perry, Ark., died at his home on November 3, aged 47 years.

Dr. JOHN AUGUSTUS HORGAN of Boston, Mass., a graduate of the Harvard Medical School in 1888 and a member of the American Medical Association and the Massachusetts and Suffolk District Medical Societies, died after a short illness, following a surgical operation, on November 11, aged 50 years.

Dr. SAMUEL P. BRUNDIGE of Marion, Ind., a graduate of the Medical College of Ohio, Cincinnati, in 1872, died at his home from paralysis on November 9, aged 77 years.

Dr. LEONARD W. CARPENTER of Trumansburg, N. Y., a graduate of the Cleveland, O., University of Medicine and Surgery, in 1865, a veteran of the Civil War, and formerly instructor in the Homeopathic Medical College, Cleveland, died at his home, after a long illness, on November 8, aged 81 years.

Dr. EUGENE A. HUTCHINS of Minneapolis, Minn., a graduate of the Berkshire Medical College, Pittsfield, Mass., in 1862, and a member of the Minnesota State Medical Association and the Hennepin County Medical Society, died at the Asbury Hospital, Minneapolis, on November 9, aged 76 years.

Dr. ELLA S. WEBB, formerly of Oxford, Pa., died at St. Paul, Minn., on November 15. She was graduated from the Women's Medical College of Pennsylvania in the class of 1885.

Dr. WILLIAM B. BULLOCK, for 56 years a practitioner at Wilmington, Del., died at Philadelphia on November 18 at the age of 90 years. He was a graduate of the medical department of the University of Pennsylvania and one of the founders of the Delaware Hospital.

Dr. JOHN E. STEPHENS of Joliet, Ill., a graduate of the Illinois Medical College, Chicago, in 1898, died at his home on October 31, aged 65 years.

Obituary.

CHARLES SEDGWICK MINOT, Sc.D., LL.D.

BOSTON, MASS.

PROFESSOR CHARLES SEDGWICK MINOT, Professor of Comparative Anatomy at Harvard University, and director of the Anatomical Laboratories, author of several works on embryology, and inventor of two widely used forms of microtomes, died at his home in Milton, Mass., near Boston, on November 19. Prof. Minot was born in Boston on December 23, 1852, and was educated in that city, graduating from the Massachusetts Institute of Technology in 1872, with the degree of B. S. He continued his studies at the Universities of Paris, Leipzig, and Würzburg, and in 1880 entered the Harvard Medical School as lecturer on embryology and instructor in oral pathology and surgery. In 1883 he became instructor in histology and embryology, in 1887 assistant professor, in 1892 professor, and in 1906, James Stillman professor of comparative anatomy and director of the laboratories. In 1912-13 he served as Harvard Exchange Professor at the Universities of Berlin and Jena.

The value of Dr. Minot's research work into the origin of life was widely recognized, and he was the recipient of many honorary degrees. In addition to the degree of Sc.D. received from Harvard in 1878, he received those of LL.D. from Yale, 1902; honorary Sc.D. from Oxford, 1904; LL.D., from Toronto, 1906, and LL.D. from St. Andrew's, Scotland, 1911. He was a fellow of the American Association for the Advancement of Science, and had served successively as secretary, general secretary, vice-president, and president; a corresponding member of the British Association for the Advancement of Science, the Société de Biologie, Paris, the Physikalisch-medizinische Sozietät, Erlangen, the Accademia Reale, Turin, and the Académie Royale de Médecine of Belgium; and a member of the National Academy of Sciences, the Association of American Anatomists, the New York Academy of Sciences, the American Physiological Society, the Massachusetts Zoological Society, the Boston Society of Natural History, of which he was president in 1897, and the Anatomische Gesellschaft, Jena.

Correspondence.

OUR LONDON LETTER.

(From Our Regular Correspondent.)

THE WAR AND THE SOCIETIES—EXHIBITIONS OF CASES AND NOTES.

LONDON, November 7, 1914

THE medical schools are feeling somewhat the effect of the war in lessening the new entries of students for this session, though to a less extent than many anticipated. The London Hospital has an increase over last year. Of its senior students about 80 have gone to the front as have also several of the staff, but the usual work is carried on. At St. Thomas's Hospital the number is only slightly under the average, and the same may be said of St. Bartholomew's, while at Guy's the average is reached.

The Red Cross Society is most active. Sir A. Sloggett, Director-General of St. John's Order, is at the front representing both societies and is assisted by Sir A. Crossley. The order has 107 hospitals in England with 4,610 beds, as well as 78 convalescent homes with 2,665 beds. A large proportion are in full work.

The war also intrudes into the proceedings of most of the medical societies, though it is early at present to look for more than notes and items of temporary interest. Several of the societies have been devoting themselves to the exhibition of cases rather than to set purposes.

The Royal Society of Medicine made a good show; the Section of Obstetrics and Gynecology opened with specimens and records of cases. Dr. Russell Andrews related a case of hemorrhage after the menopause set up by a rupture of a vein in the endometrium, in a patient of 49. A tumor was found reaching above the umbilicus; at operation it proved to be a degenerating fibroid; this did not bulge into the interior cavity, which was, however, enlarged and there were two dilated veins on the lining, one with a visible opening and blood came out of this on squeezing the organ.

Drs. Giles and Lockyer showed a case of ovarian pregnancy in a patient of 32 who sought advice for sterility—the period having missed once but having been resumed for six months. Ectopic gestation having been diagnosed, operation was performed when the tumor was found on the right side. With the epidiascope Dr. Lockyer demonstrated that (a) the pregnancy sac was surrounded by a capsule of ovarian stroma; (b) an amniotic sac in which no foetus had been found; (c) chorionic villi with their mesoblasts undergoing degeneration; (d) calcarious deposits in blood-clot around these villi; (e) decidual reaction in the connective tissue of the medullary part of the ovary, also in the cortical substance; no lutein lamina investing the sac. It seems that the embryo had died and the amniotic sac had become dilated by hydraninios.

Dr. Giles showed slides of chorion epithelioma and gave the histological report of Drs. Dudgeon and G. Ley; on this case Drs. Bell and Spencer made some remarks. Mr. Malcolm showed a fibromyoma uteri complicated with diffuse papilloma of the interior of the womb. A general opinion was expressed that the specimen was really an adenocarcinoma. Dr. D. W. Roy reported a case of puerperal eclampsia which was fatal through rupture of a subscapular hematoma of the liver.

The question of making an intestinal fistula after operation on the abdomen with the object of facilitating recovery was brought before this society by Mr. J. D. Malcolm in relation to the state often spoken of as septic peritonitis and thought to be due to intestinal paresis, but which Mr. Malcolm said would be more correctly spoken of as stasis on account of some peristaltic feebleness. When opium was freely given after every abdominal section the cases did well, but if no gases escaped from the anus the patients always died—not later than the fifth day and a slight spreading peritonitis was found P. M., but this could not be the cause of the symptoms and was only a consequence of the mode of death. Modern treatment, stimulation of the bowel and rational feeding, instead of opium and starvation was advocated and cases related in support of this plan: in two a small tube was inserted into the small intestine and in a third into the cecum, with immediate relief. In all three the bowel resumed its functions. In a fourth case a second operation was done, but the patient died. A fistula should not be made without necessity, but sometimes it would save a life—not in a septic case. In a weak patient when an expensive operation would be likely to be fatal the formation of a simple fistula might bring about a cure.

In the Dermatological Section Dr. Pringle, the president, showed a lichenous eruption in a female of 57. It occupied large areas of body and limbs and consisted of planate and acuminate papules. He doubted whether to class it as pityoriasis rubra pilaris, though he leaned to that diagnosis as did two or three members. Dr. Graham Little showed a case of lichen planus and one of granuloma on the site of an old pigmentary nævus. Dr. Sequeira showed a patient with indurated nodule slowly increasing on the chin, suggesting the diagnosis of sarcoid with which the president agreed. Also a case of myxosarcoma of the skin of face and forehead in a patient whose foot was amputated four years ago for chondrosarcoma. Mr. Samuel had a patient with symmetrical pigmention of the beard region so much like *x*-ray burn that several members expressed the opinion that it was such and that the patient was not giving an exact history. Dr. Adamson brought a case of nodular lesions on the face, giving an appearance of leprosy; there was also definite thickening of the nasal bones analogous to rheumatic nodules. The president said it reminded him of erythema diutinum. Dr. P. Weber considered it a form of leontiasis ossium. Dr. Pernet had cultures of favus and ringworm. Dr. H. MacCormack showed a case with lichenous lesions on the face, he thought was a tuberculiva.

The Æsculapian Society also had a number of cases shown by Dr. Ashdowne on the 23d net. Dr. D. Ross, past president, in the chair. 1. Acromegaly in a man of 37 admitted for hernia. 2. A man of 47 with tumor on left side of pelvis, extending to the inguinal region and round to the perineum, traceable through the obturator foramen; a second tumor higher up in the position of the descending colon. After admission to the hospital two or three ounces of blood passed. Operation considered inadmissible on account of extent of disease. 3. A boy of 9 fell from a swing ten years ago—three weeks later pain on walking came on. Tuberculosis was suspected and extension applied for eighteen months; this has been tried again lately. On admission dislocation of femur upwards and forwards with leg shortened (five-eighths inch) diagnosed. As he could walk now (he is 19) up to three miles without suffering, it was thought better not to inter-

fere. 4. Skiagram of stones in gall-bladder. There were some other cases of stone, one about 2 inches by ¾ inch found P. M. in the cystic duct of a woman who died at 88 and never had symptoms of stone. Another in a boy of 6 from whose right ureter a calculus 1 inch by ⅜ inch was removed; it had not caused obstruction of urine, a cul-de-sac having been formed. Later a second stone was removed. Gravel was still being passed.

Sir J. Crichton-Browne, addressing the Sanitary Inspectors' Association on the war in relation to sanitation, said the benefits conferred by Germany's contribution to it had been more than counterbalanced by her selfish ambition, and her recent crimes and outrages on civilization. Inasmuch as a good deal had been done in the past to reduce the ravages of smallpox, typhus, typhoid, and tuberculosis, so he believed still greater results would be achieved under the free and enlightened epoch which was about to open up. The starting point of this epoch would be knowledge gained in the war. The successful work carried out in camp sanitation, the open order and no overcrowding as opposed to the close formation in resisting typhus combined to prevent the devastation of armies in the past. Unfortunately typhoid is still a serious menace and he hoped anti-typhoid inoculation would be pressed forward. The wastage due to disease had lately been exceptionally small, and an Italian who had visited all the armies in the field assured him that the British soldier was the cleanest, best fed, and healthiest of all. With these moral and physical qualities we should not doubt their final success over dirty and demoralized millions, however courageous. When the Allies had squared accounts at Berlin we might perhaps "study war no more" for a time. But we should have an army yet awhile and in it a special sanitary corps under the army medical department and with suitable military rank. Valuable work would be done by it, *e.g.* in regard to tetanus, of which the bacillus can be attacked while localized in the wound; once diffused and combined with the nerve cells antitoxin serum seemed of little avail.

THE FLAT STOMACH TUBE; ITS USES AND LIMITATIONS.

To the Editor of the Medical Record:

Sir:—For the past ten years the writer has found that a flat stomach tube is of distinct service in certain cases in which the use of the ordinary stomach tube is beset with difficulties. Resembling the latter in every respect except that the cross-section is flattened rather than round, the flat stomach tube is adapted for the following uses: Conforming somewhat in shape to that of the esophagus and being more flexible than the ordinary stomach tube, the flat one may be introduced more easily and quickly. In nervous patients these advantages are appreciable. But the flat tube is not adapted for routine use. It cannot and should not be used for lavage, for the particles of food obstruct the lumen of the tube and render lavage difficult. It may, however, be used for the removal of a test breakfast or for the removal of the stomach contents of a patient when a prompt chemical analysis of even a small amount of gastric contents may suffice for purposes of diagnosis. The flat tubes are made in the various sizes. The ease with which they may be introduced is their chief point of superiority over the ordinary tubes. The fact cannot be emphasized too strongly that the flat tubes should not be employed for lavage.

1. Cancer of the Uterus. With Special Reference to the Possibilities of Cure by a Radical Abdominal Operation. Farrar Cobb.
2. Cancer of the Rectum. D. F. Jones
3. Cancer of the Bladder. A. L. Chute.
4. Cancer of the Prostate. H. Binney.

1. Cancer of the Uterus.—Farrar Cobb states that the two most important questions in regard to this subject are: (1) How can the public and the medical profession be taught the importance of early diagnosis and the possibilities of cure by a radical operation? (2) In what cases is a radical operation justifiable? In answering the question as to what is an operable case, the author notes that if the entire pelvis is filled with a hard mass, the uterus fixed, and the vagina markedly involved, there is no doubt but that such a case is inoperable, but in many cases no bimanual examination, with or without an anesthetic, can determine positively that the case is not one for radical treatment, because fixation of the uterus and indurated masses in one or both broad ligaments are not infrequently due to inflammatory tissue, adhesions, pus tubes, or cysts. Even if fixation and induration of the broad ligaments is due to cancer, such cases should have the advantage of exploratory laparotomy, because it is certain some of the apparently desperate cases, even those involving the bladder, can be cured. Of Wertheim's cured cases there were no less than 10 per cent. that had been considered inoperable by very worthy men. The general condition of the patient must be considered carefully, and the long and tedious abdominal operation should never be attempted in feeble subjects; it is contraindicated also in the presence of marked adiposity. In such cases vaginal hysterectomy should be substituted. In certain of the adipose cases it may be possible to do a paravaginal or radical vaginal hysterectomy, the operation of Schuschardt and Schauta. The important factors in the operation are: (1) The preliminary preparation; (2) the anesthetic, with special reference to the prevention of shock; (3) the abdominal incision; (4) the freeing and handling of the ureters; (5) removal of the parametrium and glands; (6) control of hemorrhage; (7) prevention of peritoneal infection and implantation metastasis from the growth itself, and (8) drainage and after-treatment.

2. Cancer of the Rectum.—D. F. Jones concludes that the results obtained in carcinoma of the rectum depend almost entirely upon the character of the growth and its duration, and comparatively little upon the operation done; that is, they depend upon the vigilance of the patient and the vigilance and thoroughness of the physician and surgeon. Certain cases in which there is much tenesmus demand a radical operation, even when hopeless, simply for the relief it gives, which relief is not obtained in many cases with a simple colostomy. Theoretically the combined abdominosacral operation is the operation of choice. Practically the mortality is too high except in selected cases. The statistics of late results are not sufficiently good to warrant taking the extra risk in the obese, the feeble, and in men over fifty. The combined two-stage operation, if the second stage is done under spinal anesthesia, gives

a mortality between 15 and 20 per cent. A serious objection to this operation is the danger of infecting the denuded area with cancer cells brought through the lymphatics from the growth. The Kraske operation is the operation of choice in the obese, the feeble, and patients over sixty.

11. Meningococcic Empyema. A. I. Rubenstone.

1. Exophthalmic Goiter.—R. S. Fowler states that in preparing patients suffering from this condition for operation and also from goiters of other types which present or have presented an overactivity of the gland, it is especially desirable that the fluid in the tissues be conserved. For this reason purging is contraindicated and for several days before the operation a large amount of water should be ingested. On the evening before and on the morning of operation a colon irrigation is given. Patients who have had the slightest dilatation of the heart should not be prepared for general but for local anesthesia, for the reason that in the hands of the most skillful anesthetist a slight accumulation of mucus in the bronchi might put too much strain on the already dilated heart. Iodine is not used to prepare the skin as its absorption might cause an increase of thyroidism. For the same reason antiseptics are not used at the operation. One-half hour before the time set for the operation, morphine sulphate, one-fourth grain, and atropine sulphate, one one-fiftieth grain, should be administered hypodermically. The operation should not be performed during an exacerbation of the disease. Lately there has been presented a method of anesthesia which fullfils important indications, namely, rectal ether anesthetization. For the prevention of fear on the part of the patient which would set up an acute hyperthyroidism, and the necessity of avoidance of any further burden on the heart through excessive mucus, rectal anesthesia is indicated. Complications are prevented by keeping from the patient the knowledge that she has been operated upon. The tissues are also furnished with a large amount of fluid to wash the blood free from the toxins or whatever substance has been thrown into the blood by traumatism to the gland and by traumatism set up through mental effect. In these cases it is well to give hypodermoclysis with 500 to 750 c.c. immediately after operation. In case the Murphy rectal drip is not retained on account of intestinal relaxation, repeated hypodermoclysis should be used (250 to 500 c.c. every three hours) in case hyperthyroidism develops. All patients are given fluids by mouth as soon as anesthetic vomiting has ceased, and a return is made to normal diet as quickly as the stomach will tolerate it. The immediate mortality under proper precautions is low. In the author's clinic there were three deaths in the last fifty cases. Ordinary goiter should have no mortality unless the tumor is of extreme size or presents cancerous degeneration. Exophthalmic cases always present an element of risk when brought late to the surgeon. For this reason they should be kept under observation until the time comes when the hyperthyroidism is at the lowest ebb. That is the time for operative interference and the method of operation should be as judiciously chosen.

2. Artificial Cultivation of the Rabies Virus.—F. Proescher points out that in several previous communications he described a microorganism found in smears and sections of the central nervous system of rabbits, dogs, and human beings infected with fixed and street virus. With a modified Gram stain and later with antiformin Gram, he demonstrated the existence of numerous cocci and bacilli. Further investigation showed that these microorganisms could be substantively stained with certain anilin dyes belonging to the thiazin group, methylenazur, methylenviolet, and toluidinazur, etc. It was found that only the carbonates or the free bases of these dyes were capable of staining these microorganisms, while the mineral acid salts gave inconstant or negative results. The inoculation of cultures into rabbits, rats, and a monkey produced rabies.

9. Methods of Lavage.—By J. P. Sawyer. (See MEDICAL RECORD, September 19, 1914, page 529.)

10. The Present Situation in Tuberculosis.—F. Tice states that tuberculin reactions, either positive or negative, are of no material assistance in diagnosis. The degree of skin sensitiveness is no measure of the activity or latency of the tuberculous infection. Tuberculin as a therapeutic agent is rapidly losing in repute and the indications justify the prediction that it will soon be quite generally discarded. The important determination in any case is the amount of immunity as estimated by laboratory and biological methods.

11. Meningococcic Emypema.—A. I. Rubenstone reports a case of this condition and states that a review of the literature reveals extremely few reports of lesions outside of the cranial cavity from which the meningococcus was isolated, unless in association with meningococcic meningitis. The presence of the meningococcus in the nose, throat, and ear, of not only diseased, but of a percentage of healthy individuals, has been conclusively proved. Taylor reports a case of suppurating joint due to the meningococcus. The organism has been recovered from the blood in cases of sepsis by Liebermeister, Andrews, Portret, Simon, Gwyn, and others. Warfield reports a case of malignant ulcerative endocarditis from which he cultivated the meningococcus.

5. **Alcohol Injections in Neuralgia.**—W. Harris cautions against the injection of alcohol directly into a mixed nerve, such as the sciatic, on account of the motor as well as sensory paralysis thereby produced. Many patients who have been thus operated on have escaped paralysis by their good luck in the operator missing the nerve trunk and injecting around its sheath. In chronic trigeminal neuralgia the first division is seldom involved alone, the second being usually also implicated. The supraorbital is the only branch of the first division which the author attacks. Attempts to reach the infraorbital branches are regarded as dangerous and needless. The second division of the superior maxillary nerve can be reached with advantage either at the foramen rotundum in the sphenomaxillary fossa or at the exit of the intraorbital nerve on the cheek. In the majority of cases the pain is referred to the upper jaw and the nerve must be attacked at the foramen rotundum; this is difficult while the other injection is easy. The author uses two routes for this posterior injection; the first, and preferably, through the cheek in front of the coronoid process and behind the superior maxilla. If the coronoid process of the mandible comes too far forward or the antrum bulges backward, it may be hard to direct the needle between these parts and in front of the external pterygoid plate so as to enter the sphenomaxillary fossa. In such cases the author tries to reach the nerve from behind the coronoid process, passing the needle through the cheek about 4 cm. in front of the middle of the internal auditory meatus on the line drawn from the incisura notch to the bottom of the ala nasi so as to pass over the bottom of the sigmoid notch on the lower jaw. With this the needle passes slightly upward and forward and the pterygoid plate is felt for. The injection of the third division at the foramen ovale is much more certain and easy. For this the author uses roughly Levy and Baudouin's line. Almost always he finds loss of taste occur immediately after injections of the third division of the fifth nerve confined to the anesthetic half of the tongue in proportion to the depth of the anesthesia. This lasts as long as the anesthesia and the author has seen it two years after injection.

6. **Physical Therapy.**—W. L. Bierring emphasizes the rôle of physical therapy in a general hospital. The best methods are not always the most costly and improvised apparatus may often be serviceable. The Brand bath is serviceable in typhoid fever and prolonged warm baths, hot packs, etc., are of value in various forms of cerebral irritability, skin affections, and in nephritis. Dry heat is of value in numerous neurotic and rheumatic troubles and within the past thirty years massage has come into favor as a well recognized therapeutic measure. In many diseased conditions a systematic combination of several forms of physical therapy is necessary to produce the best results and there can be no question that as physical therapy loses its proper relations and is neglected by the general hospitals, it favors the establishment of sects and pathies for its use which are distinctly undesirable.

10. **The Tonsils as a Habitat of Oral Endamebas.**—A. J. Smith and M. T. Barrett state that in connection with work recently carried on by Smith and Barrett indicating that the parasitic amebas of the mouth hold an important relation to the etiology of pyorrhea alveolaris and that by the use of emetine as an amebicide these organisms may be destroyed and the pyorrheal lesions cured, they have sought to determine whether these protozoa may not find their way also into the tonsils and there perhaps be of importance in determining or in maintaining certain of the inflammatory lesions of these structures, at least with or without associated systemic complications. At the present time only the first of these propositions can be said to be proved, that is, that these parasites actually at times involve the tonsils. The condition of the tonsils of persons in whom they have been found infested and the behavior of several positive cases with systemic complications after the administration of emetine, however, are decidedly suggestive and encouraging to continued investigation now in hand.

12. **Wassermann and Luetin Reactions.**—E. B. Vedder and W. B. Borden record the results of their investigations carried out in the Soldiers' Home at Washington, D. C. The Wassermann and luetin reactions do not give corresponding results. The plus reaction to the luetin test may be considered a positive reaction. The plus Wassermann, on the other hand, is not diagnostic unless confirmed by history or physical signs. But even if one count double plus and plus reactions as a positive indication of syphilis for both the Wassermann and luetin tests, and the plus minus and negative reactions as negative, it is apparent that while by the Wassermann reaction there are only 156 positive out of 744, or 20.82 per cent., by the luetin test there are 239 positives out of 744, or 32.11 per cent. The luetin test is therefore more delicate than the Wassermann reaction as a routine procedure. The authors have performed the luetin test on a considerable number of persons in whom syphilis could be excluded and have never obtained a positive reaction. The great majority of the patients in this series who gave a positive luetin reaction had some history or physical signs indicating syphilis.

14. **Neurological Examinations.**—J. Grinker criticises the common neglect of a thorough physical examination in mental cases. The mental picture seems to overshadow the neurological aspect in many institution examinations; even skilled examiners may be guilty of errors or oversights. The most commonly overlooked organic diseases in the supposedly insane are brain tumor, cerebral arteriosclerosis, syphilis, and nonspecific vascular brain diseases; and in private practice, drug addictions, postinfectious and posttraumatic deliriums, and the psychoneuroses. One of the most humiliating and dangerous errors is the mistaken diagnosis of insanity in a case of brain tumor. The resemblance of many drug addictions to insanity is also pointed out.

6. The Action of Drugs on Plants. J. C. Bose.

2. **The Wounded in the War.**—D'Arcy Power discusses a few of the surgical lessons which have been learned in a base hospital in London. Bullets and even pieces of shrapnel casing often passed through fleshy parts without doing much damage. The points of entry and of exit were clearly seen. Both had healed satisfactorily and nothing remained to be done except to feed and nurse the patient for a few days before he was discharged into a convalescent home. In other

cases the wounds of entry and exit were suppurating but the track which must have existed between the two was soundly healed. No sinus remained and so far it has not been necessary to lay open any such track. It seems clear, therefore, that the most frequent sources of infection are the skin of the patient or some subsequent contamination. The infection is not due to the clothing, for in several cases pieces of shirt or puttee were removed from wounds which had healed soundly and which had been reopened on account of the pain they had caused. The cases have become more severe as the battles have been fought nearer England. Gangrene due to an anaerobic organism has occurred in several cases. Early operation has been performed with success and the very great value of a free application of a 2½ to 3 per cent. alcoholic solution of iodine has been determined. This should be applied to the raw surface of the flaps at the time of amputation and care should be taken to allow of free drainage by not putting in too many sutures. A few cases of tetanus with a long incubation period have occurred, but the majority of the patients affected with this disease have not reached the base hospitals, as they have been treated at the stationary ones. The war has revealed an interesting series of cases which for the present must be called "nerve concussion," about the treatment and prognosis of which much has still to be learned. When they occur in connection with the spinal cord they may be the result of a blow from a bullet or piece of shell, perhaps no nearer than upon the pack which the soldier is carrying. There is no external wound but the patient becomes paraplegic. Such a condition is analogous to "railway spine," though it is not associated with neurasthenia at least in the early stages which have come under observation at the present time. The net result of the work appears to show that as in ordinary civil practice meddlesome surgery is generally bad surgery.

5. Accessory Spleen Causing Acute Abdominal Pain.—R. C. Alexander and A. Romanes state that the frequency with which the pathologist meets with accessory spleens at necropsies makes it rather remarkable that their presence is rarely noted by the operating surgeon. Adami and Nicolls note that they are found in 11 per cent. of all necropsies and that they may reach the size of a walnut. Their situation varies. They may lie in the gastrohepatic or gastrocolic omenta or even in the stomach wall itself. The author reports the case of a woman 25 years of age in whom attacks of abdominal pain were caused by the presence of an accessory spleen. The cause of the pain is attributed to congestion of the viscus from torsion of the omentum obstructing the return blood flow. There was no necrosis visible and there had been apparently no arterial obstruction.

1. Some Observations on the Significance of Blood-Pressure Readings in Man. J. A. MacWilliam and G. Spencer Melvin.
2. The Barber-Surgeons Company. T. G. Lyon.
3. Insects and War: Mites. A. E. Shipley.

1. The Significance of Blood-Pressure Readings.—J. A. MacWilliam and G. Spencer Melvin emphasize the importance of estimating the minimal or diastolic pressure, a practice which is now becoming more generally recognized. With the easy applicability of the auditory method there is no difficulty in the way of its routine use. Apart from the influence of aortic diastolic pressure in determining the strain upon the closed aortic valves, and the resistance to the opening of these valves by the ventricular systole, the distending force of load which it imposes on the arterial tube is of prime importance. The properties of the arterial wall are such as to show relatively great effects from long-continued tension as compared with the transient application of distending force, as in the brief rises of pressure that constitute the systolic waves. The greater proneness of the leg arteries to degeneration is especially associated, in all probability, with the high diastolic pressure in the erect position, rather than with the concomitant increase in the systolic level which is also induced by the influence of gravity. The evidence available at present is insufficient to show in what measure the injurious effects of an excessive diastolic pressure are to be attributed to the influence of mechanical strain upon the tissue elements of the arterial wall, and to the influence of a high distending pressure on the flow of blood and lymph in the walls of the arterial tube. The more common conditions when the circulation is defective are: Low systolic and diastolic readings (as in hemorrhage, shock, etc.), or a systolic pressure which may be normal or even higher, attended by an abnormally high level of diastolic pressure, as in some cases of slow cardiac failure. Here the peripheral resistance is increased, keeping up the systolic pressure, notwithstanding a poor cardiac output, but this involves a high diastolic pressure—that is, a small pulse pressure and associated defective movement of the blood. It is only in a small minority of cases with thickened and contracted arteries that a notable reduction of the systolic reading is induced by local compression. If the pressure readings from two limbs differ markedly on account of the occurrence of a special form of closure in one artery as compared with the other, the pulse persisting much longer in one than in the other, it might be possible to elicit special evidence bearing upon the different conditions. In a case studied by the authors it was noteworthy that the systolic readings were much higher with the armlet on the calf of the leg than when on the thigh; the latter often nearly agreed with the arm. They conclude from such results that the systolic pressure was really the same in the arm and leg, though the latter pulse was strikingly cut down to one of very small volume, which persisted until the compressing armlet pressure had been raised much higher. The authors interpret this result as being due to a different form of closure in the arm and leg arteries respectively, and they regard the leg arteries as the ones in which the behavior of the tube under compression was peculiar. The presence of contraction—that is, muscular resistance—is very important in human arteries when associated with certain abnormal structural conditions, determining the occurrence of special features in the process of closure of the vessel by external pressure, and thus leading to different readings of obliteration pressure that do not correspond with differences in the actual systolic pressure.

October 5, 1914.

Schizothymia and Cyclothymia.—Kohnstamm characterizes schizothymia as follows: the simplest form is comparable to one aroused from deep hypnosis with a paralyzed arm. He is unable to remember anything about the onset of the paralysis. Characteristic of the schizothymiac are his amnesic troubles. Psychic shock may produce dissociation of the same sort. The restoration of memory continuity as effected by psychotherapy is known as palinmnesis. Schizothymic phenomena are comprised under what we call at present hysteria. In as far as the latter means nosophilia or love of or attraction toward disease, the author objects

to placing schizothymia in the hysterical category. The two conditions may, however, coexist in the same subject. The author makes use of the simile of the "sandbank" in connection with schizothymia, using that word in the sense of a shoal. If the depths of the water represent the deep recesses of the subconscious mind, the shoals are equivalent to every day consciousness. Disturbances arising in the former may make themselves felt in the latter. The psychic shock caused in a woman by the accidental suffocation with illuminating gas of two servant girls produced a state of insomnia associated with fear of escaping gas, and this in time culminated in a state of excitement which from its periodic recurrence was classed as cyclothymia. The author believes that related phenomena have a similar mechanism; in other words the cyclic character is not strictly endogenous, being determined by outside influence, just as are the recurring mental troubles of pregnancy or of certain seasons of the year. Genuine cyclothymia represents an alternation of exalted and depressed states such as culminate in manic-depressive insanity, and in the depressive phase we may see symptoms which properly belong to schizothymia. For psychoanalysis of the latter the author does not find Freud's method suitable, and prefers the Frank hypnotic procedure, which is at the same time diagnostic and therapeutic. Through the resulting palinmnesis the subject becomes capable of psychic orientation. Cyclothymia cannot be thus successfully dealt with—the patient can only be placed under conditions most favorable for the wearing off of his symptoms. The condition may disappear suddenly. Schizothymia may lurk under the picture of atypical cyclothymia. Here belong such conditions as periodical hysteria, anxiety, and compulsion neuroses, dyspepsias, neuralgias, etc. In conclusion he states that schizothymia is equivalent to "sandbank symptoms" or surface effects of deep-seated causes.

New Experiences in the Treatment of Smallpox Scars.—Unna, Jr., discusses a number of resources which are chiefly old. The indications are to level the protuberances and fill up the depressions. The most trustworthy procedure is polishing with smoothing stones, powders, pastes, and soaps. Compressed pumice stone answers well, but the ordinary commercial article will not do as good work, although it may be used in the absence of the other. Sand may be also used, especially in soap, and chalk is useful in pastes, etc. The skin must be irritated until it weeps slightly, after which it may be dressed with cold cream. Naturally in smallpox scars there is a wide field for ordinary surgery, for excision, leveling, transplantation, etc. On a smaller scale one may scarify crosswise with a very fine knife. The chief objection to electrolysis is the painfulness of the method. Much more recent than the measures thus far noted is iontophoresis with thiosinamin. Ten per cent. of the latter is added to a saturated solution of salicylic acid, and a pledget of cotton moistened therein is applied locally as the positive pole. The results from this method are said to be remarkably good. But carbonic acid snow is perhaps the most trustworthy resource, for not only does it reduce projections but fills out depressions as well. A very careful and elaborate technique is given for its proper use.

Münchener medizinische Wochenschrift.

October 13, 1914

"Traumatic Malacia" Following Fractures.—Gaza states that chance cannot be responsible for a certain group of phenomena seen in the bones after violence and especially since the *x*-ray era. These phenomena have been studied in the vertebræ (Kümmell's kyphosis), in the neck of the femur, and especially in the small bones of the wrist and foot. Köhler's disease, a term applied to softening of the scaphoid of the foot after violence, is one of the best known types. The author has seen two cases of so-called traumatic malacia in the semilunar bone of the wrist, the lesion described and named by Kienbock in 1910. In these cases a linear fracture had been in evidence and the presumption is that the softening does not occur save as a result of fracture. It will, however, be recalled that "Köhler's disease" was not originally traced to fracture nor do we yet know that such a traumatism is responsible for it, although in future cases this possibility must at least be rigorously excluded. It must be remembered that cases of atrophy and softening of certain bones and parts of bones while traceable to violence, have not been connected with latent fractures at all. The author sums up by stating that in such cases the lesion is a linear fracture accompanied perhaps by some crushing of the adjacent trabeculæ or followed by a certain amount of absorption of mineral matter. As a result the skiagrams show a macular lacunar clearing up. These changes are primary. At a later period more serious deforming alterations occur and we see such conditions as traumatic coxa vara, Kümmell's kyphosis, and perhaps Köhler's disease. There is often a prolonged period of latency between the primary and secondary alterations, and the joint surfaces may become involved. In the case of the wrist bones it may be come necessary to extirpate all the compromised tissues and interpose flaps of fat.

Two Abortive Cures of Syphilis in the Same Subject.—Hoffmann reports what is doubtless a unique case although one which in theory might readily be duplicated. A man 39 years of age contracted a chancre for which his attending physician made an injection of salicylate of mercury. Salvarsan was refused and patient next consulted the author who found a typical initial lesion, spirochetes present, enlarged proper lymphnodes, no secondary symptoms, Wassermann reaction negative. An inunction cure was at once begun, with weekly injections of old salvarsan. No secondary symptoms and Wassermann reaction negative during an observation period of about six months. At this period a "provocative" injection of salvarsan gave a negative result. During this period patient had received in all 0.82 gram old salvarsan and 4 grams blue ointment in 24 inunctions. Two years and two months later patient reappeared with a new primary lesion of the penis at some distance from the site of the first. Spirochetes were present in large numbers. The proper lymphnodes were enlarged. The lesion was small and the incubation period was over six weeks. The Wassermann reaction was at first negative. The lesion was excised, and was found to be histologically a chancre. The combined treatment was at once resumed. No secondary symptoms appeared but at the end of the first week the Wassermann reaction became positive, for one test only. The treatment comprised 42 inunctions and the salvarsan injections. Eight months after the second chancre was acquired the Wassermann reaction again became positive for a brief interval but there was no further variation even when the provacative injection was given. The Wassermann reaction was also negative in the spinal fluid.

Prevention of Tetanus in the Army.—Jakobsthal states that during the present war tetanus has proved to be more frequent than had been anticipated. In the majority of cases the wounds which became infected were ill-looking and ragged. The outbreak occurred soon after the arrival of the wounded, thus showing a

relatively remote exposure. This does not appear to have been so much the case in the Franco-Prussian war. The causes are as yet obscure. One may accuse the conservative management of the wounds or the increased amount of exposure to dirt in connection with earthworks, trenches, etc. What is to be done to check this infection? In all cases of shredded wounds soiled with dirt which reach Hamburg antitoxin is at once injected. There is, however, an insufficient supply of the latter at present so that the doses have to be restricted. Ordinarily 20 c.c. suffice for prophylaxis but if much time has already elapsed the quantities should perhaps be made larger, for there is hardly any likelihood of anaphylaxis. For the wholesale production of the serum a sufficient number of good, healthy horses is indispensable and all such have been pressed into war service. The army authorities could supply for this purpose otherwise sound horses with strained tendons. Antitoxin should be available at the field hospitals. Dirt must not be blamed for all the tetanus cases for the dressing materials may harbor the germs. At present a dried fern preparation from the East Indies (pengawar djambi) is being used for hemostasis. This has repeatedly been shown to contain tetanus germs.

Deutsche medizinische Wochenschrift.

October 15, 1914.

Anaphylactic and Apotoxic Poisoning.—Von Behring states that under anaphylactic poisoning belong all cases in which a specifically sensitized individual reacts toward the sensibilizing agent. This reaction comprises the anaphylactic shock and the subcutaneous phenomena. The sensibilizing agency, which is combined with protein, loses its power when the latter is broken down to the peptone stage. All proteins in nature possess this power of combination. The anaphylactic property does not reside in the sensibilizing substance but in the antibody to which it gives rise. The substance itself is termed anatoxin when it causes anaphylaxis and is simply an antigen when it first sensibilizes the individual. The anaphylatoxin has also been termed apotoxin, as it is believed to be formed when the sensibilizing protein is changed to proteoses. It has been shown that by combining *in vitro* an antigen with an antibody a substance may be obtained which has an apotoxin action. When this is tested in an ordinary nonsensibilized individual, the picture of anaphylaxis is produced. This the author terms anaphylactoid. The intensive studies of the past four years by the author and his disciples have brought about the belief that the phenomenon of anaphylaxis depends somehow on the bloodplates or, as they are sometimes termed, thrombocytes. In the phenomenon of anaphylaxis the initial act is the agglutination of the thrombocytes. The cerebral symptoms of anaphylactic shock appear to be due to resulting embolism in the small arteries. All substances which cause anaphylactoid in nonsensibilized animals appear to do so through this same property of agglutinating the bloodplates. In regard to the other component, viz., the serum poisoning, this is perhaps most intelligible in terms which involve physical chemistry. The toxic principle appears to be a protease, resulting from a peptolytic activity exerted by the so-called cytozyme which figures in ordinary blood coagulation. The concentration of the calcium ions of the blood, however, must also be invoked to throw light on anaphylaxis.

Etiology and Clinical Diagnosis of Actinomycosis.—Dressl sums up his article as follows: Actinomycosis in man and animals depends upon an anaerobic infection with a trichomyces commonly known as the actinomyces of Wolff and Israel. In many cases there is a mixture of infection due to the presence of anaerobic streptothrix. In addition to genuine actinomycosis there is known clinically a similar condition in which the pus contains exclusively these aerobic streptothrices in a virulent form. The pus contains characteristic granules large enough to be visible to the naked eye. These are composed wholly of felted streptothrices. On the other hand, in recent cases of genuine actinomycosis when the tissues have rapidly become dissolved by the disease the pus may contain no granulations. In such cases the diagnosis must lie between actinomycosis and streptothricosis and culture tests may be required for differentiation.

Human Anthrax.—Mathias and Blohmke report a fatal case of malignant pustule in a house servant who first visited a nose and ear clinic for acute suppuration in the frontal and ethmoidal sinuses. There were in addition swollen glands on the left side of the neck. Patient had been ill but two days and had a marked constitutional reaction. The glandular swelling was found to be the enlarged submaxillary, which had rapidly increased until it had attained the size of an apple. The left tonsil and adjacent fauces, and the nasal mucosa were red and swollen. There was some tenderness over the frontal sinuses. Aside from high fever (39° C.), pulse of 120, and great thirst the patient was free from other symptoms. Diagnosis, acute catarrh of the frontal and ethmoidal sinuses and inflammation of the left submaxillary gland. Nasal discharges showed ordinary pyogenics. Patient received hot baths and locally cocaine, and began to feel much better. A profuse epistaxis soon followed, requiring a tamponnade. Two days after admission he was taken suddenly with colic and diarrhea. The tonsillar swelling had extended and now interfered slightly with respiration. There was a large paquet of swollen glands at the angle of the jaw. Before the day was over the patient collapsed. Incision into the tonsil revealed no pus. The chief symptoms were motor restlessness, frequent superficial respiration, collapse pulse, progressive cyanosis, and colic. Mental state good, no convulsions, no vomiting. Stimulants like caffein and camphor were of little avail and death occurred early on the third day. Autopsy showed thoracic contents normal, purulent peritonitis of a peculiar type, the membrane appearing highly edematous and gelatinous in the principal folds. The wall of the stomach showed the same condition, as did the inflamed sinuses. These peculiar lesions were therefore characteristic of some infectious disease, which proved on animal inoculation to be anthrax. There was a history of occupational exposure to hides. Of the numerous symptoms only the following pointed to the true nature of the process—profuse nose bleed, the infiltrated gland paquet, the abdominal symptoms, and cyanosis of nonmechanical origin.

Abnormal Cysts on Shoulders.—Eris Pritchard reports the case of a twin, aged six weeks. The mother was confined at home and was attended by a midwife; the first of the twins was delivered head first; in this one the presentation was said to have been that of a shoulder (left). The midwife, without calling in assistance, performed version, and immediately after birth the two cystic swellings were observed on the left shoulder in the position which they still retained. The infant was brought to the author's Infant Consultations when it was eight days old. At this time the two cystic swellings were slightly larger than they had been. Although each fluctuated freely on palpation they did not appear to communicate. They were stated to have increased in size since birth. Three cubic centimeters of the fluid were drawn off with a hypodermic needle; it was blood stained, and partly coagulated on standing. The swellings appeared to be of the nature of abnormal and persistent capita succedanea.—*Proceedings of the Royal Society of Medicine.*

Insurance Medicine.

Unexpected Losses of Life Companies.—Dr. J. H. Florence, Medical Director Great Southern Life Insurance Company, enumerates a few of the leading unlooked for sources of loss to life companies:

Deaths by Violence.—This includes railroad, automobile, and all other accidents, suicide, homicide, and ptomaine poisoning. There is a chance that suicidal tendency might be suspected, if the medical examiner knew the applicant's mental tendency to avoid a history of family or financial trouble.

Tuberculosis.—While this disease is contagious, we should never overlook the inherited tendency. When a true family history is given there is no difficulty in rejecting an applicant if there is tuberculosis in the family and he is young and light weight as compared to height. It is the association with tubercular subjects that is important. Most companies postpone an applicant at least three years if he or she has lived in a house with a consumptive, and five years if it be husband or wife. The local examiner should make careful inquiries along these lines. The applicant may not know the importance of mentioning these facts, is passed, gets his policy, and in two years dies from tuberculosis.

Diseases of Circulation.—Under this heading would be remote heart defects, arteriosclerosis, but the one thing that is a nightmare to the companies is deaths from unreported syphilis. It is a constant occurrence to have deaths from paralysis and apoplexy in men above forty years, who probably have recent policies. No blame should be attached to the local examiner, as scores of such applicants have few, if any, visible signs of syphilis. While nodes, scars, and other evidences should be looked for, these cases often have had just enough treatment to obliterate these external signs, and yet have blood vessels ready to rupture. In these cases we expect some saving from the use of the blood pressure instrument at the time of examination.

Kidney Disease.—When policyholders die within two years of this condition there is but one conclusion to be drawn, the local examiner failed to do his duty. The careless doctor who takes his fee, states he has made a urinalysis but has not done so, is worse than a highwayman. Also the careless examiner costs the companies far more than the crooked one, as there are very few crooked examiners as compared to the careless ones.

Stomach Trouble.—Many applicants die soon after receiving policies from the different forms of stomach trouble. The conditions are unsuspected at the time of the examination, as the applicant looks healthy. A history of an attack of "acute indigestion" a few years ago may cover anything from a belch to cancer. Two recent deaths occurred in which the parties' policies a few months old gave histories of "acute indigestion from overeating, never went to bed"; one died of cancer; the other had an ulcer.

Life insurance companies do not expect impossibilities from local examiners, but good, thorough work is to be demanded. An error in detecting any of the above-cited conditions by the examiner can cost the company not less than one thousand dollars; hence, great care should be taken in the examination of each and every applicant that losses should be confined to the natural expected causes.—*Charlotte Medical Journal*, October, 1914.

Goiter in Relation to Life Insurance.—From a life insurance standpoint it is important to remember that goiter is an exceedingly common disease, that it may occur endemically, epidemically, or sporadically, and that it may occur in any country and in any climate. Dr. Alexander Mackenzie Campbell, Medical Director Preferred Life Insurance Company, Grand Rapids, Michigan, wrote to a number of companies in the United States asking for a statement of their attitude toward goiter, and from the replies received it appears that the majority of insurance companies at the present time refrain from accepting goitrous applicants—excepting smaller forms of goiter, which are without symptoms and which have made little if any progress during a period of five years.

Dr. Campbell believes that insurance companies should assume a somewhat more liberal attitude toward many of these cases, and says that while aware of the many ways in which goiter may seriously affect the health, yet he believes that it is in its incipiency a curable disease. Campbell also believes with Kocher that goiter is a surgical disease. A high percentage of cases may be restored to permanent health after a successful operation, and if the applicant can pass a satisfactory examination in every other way he should be accepted within a few months or a year after the operation. Charles Mayo considers that "if the patient, one year after operation for exophthalmic goiter, can pass the ordinary examination, there being no dilatation of the heart or kidney symptoms, they can reasonably be accepted by the insurance company.

In operation for simple goiter, if there were no degenerations or symptoms affecting the nervous system and heart, such persons could be accepted within a few months. In operation for simple goiter there is almost no risk. If complicated by degeneration of the gland, which has caused myocardial change, the mortality is about the same as that of exophthalmic goiter or a trifle higher. The mortality in exophthalmic goiter varies from 1 to 2 per cent. About 80 per cent. make a very good recovery; the remainder are improved, but operated upon too late for complete restoration of the degenerated organs." A plea is made for the early diagnosis of goiter in its various forms, for it is a common experience in practice, Campbell says, to see many advanced cases of this disease, particularly exophthalmic, where the diagnosis is not made until irreparable changes have occurred in vital organs.

One should always be on the alert in his interpretation of such symptoms as tremor, rapid pulse, exophthalmos, and low blood pressure in the examination of applicants for life insurance. In the light of the possibilities of the surgical cure of this disease it is Campbell's opinion that life insurance companies will be forced to change their viewpoint in their consideration of these cases. Applicants who have recovered from operation because of this malady should in many instances form as desirable a class of risks as most individuals who have been restored to health by operation because of other surgical ailments.—Medical Section, American Life Convention.

Book Reviews.

INTERNATIONAL CLINICS, a Quarterly of Illustrated Clinical Lectures and Especially Prepared Original Articles on Medicine, Treatment, Surgery, etc. Edited by HENRY W. CATTELL, A.M., M.D. Volume III. Twenty-fourth Series, 1914. Price, $2.00. Philadelphia and London: J. B. Lippincott Company.

THIS volume contains twenty-six articles on Diagnosis and Treatment, Medicine, Electrotherapeutics, Surgery, Child Welfare and Medical Problems. Nearly a third of the volume is devoted to an article on Mr. Deaver's clinic in Philadelphia, and embodying a report of some seventy cases. By far the most interesting articles are two, one on the use of vaccines is pertussis by Alfred F. Hess, the other on the nephelometric method of analysis by P. A. Kober and S. S. Graves. Many of the other articles are of only slightly less interest.

EXPERIMENTS. A Volume for all who are Interested in Progress. A Complete Account of Experimental Work in Science, Invention, the Industries and the Amateur Field, with Practical Instructions and Working Directions. By PHILIP E. EDELMANN. Price, $1.50. Philip E. Edelmann, Minneapolis, 1914.

THIS small book is divided into two parts which contain, in the words of the title page, selected, grouped and graded experiments which may be repeated in a simple manner, including some of the most brilliant demonstrations in science, physics, chemistry, electricity, wireless communication, and mechanics. The second part sets forth briefly the principles of original experimenting. It is a book that the average small boy would treasure above all others, one that would lead him soon to the possession of a workshop of his own and to endless experimentation. It is fascinating and any reader would wish for the time and facilities to carry out the experiments described. The illustrations are for the most part adequate though in one or two places are wrongly numbered. Every boy should have one.

THE PRACTICE OF SURGERY. Second edition, thoroughly revised. By JAMES GREGORY MUMFORD, M.D. Lecturer on Surgery in Harvard University; Surgeon to the Clifton Springs (N. Y.) Hospital; Fellow of the American Surgical Association; Recently Visiting Surgeon to the Massachusetts General Hospital, etc. Octavo of 1032 pages, with 683 illustrations. Price, cloth, $7.00; half morocco, $8.50. Philadelphia and London: W. B. Saunders Company, 1914.

THIS is a second and thoroughly revised edition of Mumford's work, the first edition of which was reviewed in these columns in 1911. The first was good, this is better; for some of the shortcomings of the first edition have been remedied and, in most respects, we find that the text reflects the latest advances in the field of general surgery.

It is apparently inevitable, however, that omissions which strike the reviewer as important should occur, and that some subjects seem to deserve more extended notice. Coming under one or the other of these categories, we select the following: Sliding hernia of the large intestine should be clearly described, for, as pointed out by Moschcowitz, it occurs much more frequently than was formerly supposed; and the sacless type forms a very puzzling and dangerous complication for any surgeon not familiar with the condition and its treatment. The sections on the pancreas and spleen may well be amplified, for great advances have been made in the understanding and surgery of these organs in the past two or three years. Under the heading "Abdominal Ptosis," Coffee's work deserves recognition; while Lane's kinks, and Jackson's membranes have assumed an importance demanding more adequate description. Transfusion is referred to as a method of last resort, due in part to the tediousness of the operation. This applies as far as anastomotic methods are concerned, but not to the simple syringe method developed by E. Lindeman, of which no mention is made, although it presents but little technical difficulty, is certain as to results, and already widely used. The efficiency of the cystoscope in diagnosis and treatment does not seem to be appreciated, and certainly the Brown cystoscope, mentioned as a type by Mumford, has been greatly improved by Buerger; while above all, we find no mention of pyelography which has assumed almost paramount importance in the early diagnosis of hydronephrosis and many other renal conditions. Finally, artificial pneumothorax in the treatment of pulmonary tuberculosis, at least deserves mention; while surgeons throughout the world are making use of free fat and fascia transplantation, and it is a field of great promise, but we find practically nothing about it here. These defects are, however, trivial when we consider the unusual value of the work as a whole.

A TREATISE ON DISEASES OF THE RECTUM AND ANUS. Edited by A. B. COOKE, A.M., M.D. Formerly Lecturer on Diseases of the Rectum and Professor of Anatomy in the Medical Department, University of Nashville; formerly Professor of Anatomy and Clinical Proctology, Medical Department, Vanderbilt University; Fellow of the American Medical Association; Fellow and sometime President of the American Proctologic Society, etc. Assisted by WM. M. BEACH, A.M., M.D., Pittsburgh, Pa.; J. COLES BRICK, M.D., Philadelphia, Pa.; GEORGE B. EVANS, A.M., M.D., Dayton, Ohio; ALOIS B. GRAHAM, A.M., M.D., Indianapolis, Ind.; GRANVILLE S. HANES, M.D., Louisville, Ky.; LOUIS J. KROUSE, M.D., Cincinnati, Ohio; COLLIER F. MARTIN, M.D., Philadelphia, Pa.; FRANK C. YEOMANS, A.B., M.D., New York City; A. J. ZOBEL, M.D., San Francisco, Cal. Price, cloth, $5.50. Philadelphia: F. A. Davis Company, 1914.

THIS work is edited by a rectal specialist whose originally narrow viewpoint has necessarily been more or less tempered by the broadening influence of a long experience in general surgery. The result is that all the various phases are treated rationally and undue importance is not given to what are really trivialities, as is so often the case when the author has unconsciously become accustomed to consider everything merely in the light of its relation to, or influence upon, his specialty. More than half the contributions in the book are from the pen of the editor himself. The chapters by other authors are also well done, some particularly so. In addition to the sections covering the topics usually discussed in books on anorectal diseases, there are chapters on local anesthesia, the relation of rectal diseases to the general health, and on rectocolonic alimentation. The illustrations are almost uniformly good and to the point. In general we may say that the subject is covered very thoroughly; and that the teaching will be found in accord with what is recognized as the best practice at the present time, thus making it valuable for text-book use or as a work reference.

THE CLINICS OF JOHN B. MURPHY, M.D., at Mercy Hospital, Chicago. Volume III. Number III. Octavo of 215 pages with 54 illustrations. Published bimonthly. Price per year: Paper, $8.00; cloth, $12.00. Philadelphia and London: W. B. Saunders Company, 1914.

IN this number nearly the first third is given over to clinical talks on surgical and general diagnosis by Dr. Murphy and Dr. Mix, some of the more important topics being: Differential diagnosis between benign and malignant breast tumors before and at operation (in which we were glad to see the malignant nature of Paget's disease emphasized, as this cannot be done too often or too emphatically); differential diagnosis of gastric and duodenal ulcer; carcinoma of the stomach at the cardiac orifice; and the differential diagnosis of acute appendicitis, cholecystitis, and ascending urinary infection. In all of these important points are brought out in connection with the history, diagnosis, and operation of illustrative cases. A considerable part of the rest of the book is concerned with lesions of the tendons, bones, and joints.

CONTRIBUTO NUOVO ALLA ETIOLOGIA E PATOGENESI DELLA PELLAGRA. Di GIULIO ALESSANDRINI E ALBERTO SCALA. Price, 4.80 francs. Roma: Tipografia Nazionale di G. Bertero, 1914.

THE authors report ninety-four experiments on rabbits, monkeys and guinea pigs with injections of colloidal and gelatinous silica, aluminum, carbonate of soda and with different foods. Silica produced chronic intoxication in both colloidal and gelatinous states in all the animals, and the waters of the pellagrous zones containing clayey substances in suspension, produce the same intoxication when given to the animals in their food. The effects of this intoxication were obviated by intramuscular or subcutaneous injections of solutions of neutral citrate of soda. The authors conclude that the cause of the muscular atrophy observed in pellagrous patients is not mechanical but chemical and endogenous, and partakes more of a mineral than organic nature. Such muscular atrophy, they recall to the reader, is often found in mineral intoxications, such as arsenic, etc.

Society Reports.

AMERICAN ASSOCIATION OF IMMUNOLOGISTS.

First Annual Meeting, Held in Atlantic City, N. J., June 22, 1914.

THE PRESIDENT, DR. GERALD B. WEBB OF COLORADO SPRINGS, COLORADO, IN THE CHAIR.

An Historical Sketch.—Dr. MARTIN J. SYNNOTT of Montclair, N. J., gave a brief account of the way in which the idea of this society had been conceived and of the manner in which its organization was effected. He stated that the idea had first occurred to him, in 1912, that a "Society of Vaccine Therapists" made up of men who had worked in the Praed Street Laboratories might prove mutually advantageous to the members. He had therefore written to the men in the United States and Canada who had taken the course in the Inoculation Department of St. Mary's, and later to those who had studied with Metchnikoff, Ehrlich, Wassermann, and in some of the other famous laboratories of Europe. Dr. Gerald B. Webb had suggested the more concise and inclusive title for the organization, "The American Association of Immunologists," thereby widening the scope of the society beyond the original conception of the speaker. A first attempt at organization was made in Washington in May, 1913, during the time of meeting of the Association of American Physicians, but was not consummated until June 19, 1913, at Minneapolis, Minn., during the session of the American Medical Association. They had now sixty charter members and eight applications for membership. The speaker predicted that they would in a few years be one of the most important medical organizations on this continent, and said he believed with Sir Almoth E. Wright that the physician of the future would be an immunologist.

The Production, Through Immunization, of Specific Ferments Against Bacteria, as Detected by the Abderhalden Test.—Dr. GEORGE H. SMITH of Glenolden, Pa., presented this paper which was based on the fact first demonstrated by Abderhalden in his pregnancy reaction, that specific proteolytic ferments were elaborated by the body in response to the parenteral introduction of foreign protein. The writer stated that they had proposed to test the limits of this specificity of ferment production by employing bacterial proteins. Rabbits received immunizing courses with *Staphylococcus aureus*, *S. albus*, streptococcus, pneumococcus, *B. influenzæ*, *M. catarrhalis*, and with a mixture of all. The substrates were prepared from the organisms by washing and drying heavy suspensions. The technique of Abderhalden was employed, using 1.5 c.c. of serum and 10 milligrams of the substrate. The results showed that each serum was able to effect a marked degradation of the homologous substrate while with the other substrates reactions were negative. Several slight non-specific reactions were obtained with streptococcus and *Staphylococcus albus* substrates. It had been demonstrated that these were due to accidental infection. Sera from rabbits immunized with the mixture degraded all of the substrates. The results indicated a relatively high degree of specificity in ferment production.

Professor C. E. L. MILLER of Richmond, Va., said that Dr. Smith had given a very good demonstration of the problem he had attempted to solve. From the biological standpoint it fitted in with and corroborated what they had been thinking for some time. It was obvious that a unicellular organism must of necessity form a ferment if it was to live. If the protein food materials outside the organism were insoluble, as they often were, they must be made soluble by digestion that they might diffuse into the organism. To accomplish this the unicellular organism separated from itself something that they had designated an enzyme, and this power of enzyme formation was one of the striking and essential characteristics of unicellular organisms. It was becoming clearer and clearer that a human body was made up of a mass of cells that were in many respects still unicellular creatures; Nature in working up from the unicellular to the multicellular had not so much produced a new kind of creature as a colony or interdependent community of unicellular forms, each one of which to a large extent retained its primitive functions. The function of reproduction was well shown in the process of repair. The function of motion was uncertain in even the unicellular forms. The function of enzyme formation was probably involved in all cell nutrition and could now be demonstrated in the laboratory by means of the Abderhalden reaction. That each cell maintained to a large extent an independent existence capable of motion, nutrition, reproduction, and response to stimulation had lately been demonstrated by the actual cultivation of tissue cells without the body. All these factors worked together and tended to build up a view of the nature of our bodies that they had not held before. This work of Dr. Smith showed clearly the specific nature of the ferments produced. He had seemed to show the cells as possessing an intelligence. They were presented with the problem "Devise and produce an enzyme to dissolve the bacteria injected." This was an entirely new problem and yet the cells responded with an enzyme so perfectly adapted to its functions that it would dissolve the substance in question and nothing else. By using such enzymes they often distinguished between substances otherwise indistinguishable.

Experience with Abderhalden Serum Diagnosis Reaction for Carcinoma.—Dr. OSCAR BERGHAUSEN of Cincinnati, Ohio, read this paper. He said that in their work the technique of Abderhalden had been followed for the most part, the only important deviation being that the serum was subjected to a preliminary dialysis before adding tissue. It was found that the serum of carcinomatous patients was most apt to digest tissues which corresponded most closely to the affected region of the patient. These results led to the conclusion that probably the embryonal origin was of some importance and according to this assumption those tissues that most probably represented the anatomic pathology of the case were selected. For the most part it was found that serum from a carcinoma patient digested tissue of the same origin as the affected tissue. Although serum usually digested only certain tissues contrary results were occasionally obtained. The results of cases studied showed that with the exception of one case each of pregnancy, elephantiasis, empyema of the thorax, and tuberculosis of the spine all control cases gave negative reactions. Serum from malignant cases digested some form of malignant tissue in every instance.

Abderhalden's Pregnancy Test.—Dr. WILLIAM WHITRIDGE WILLIAMS and Dr. CLARENCE B. INGRAHAM of Denver, Col., presented this communication. After giving a brief explanation of the theoretical basis of the Abderhalden test, they stated that it had been applied to known and doubtful cases of pregnancy. Aside from the strict observance of the Abderhalden technique, the writers emphasized that the blood should be taken from a convenient vein under strict aseptic precautions with a dry needle kept in a sterile container. The serum should be allowed to clot spontaneously as centrifugalization frequently caused hemolysis. The serum should contain as few dialysable substances as possible; it must be absolutely free from hemoglobin and from formed elements. If any of these conditions were disregarded, experience had shown that incorrect results were obtained. In the series of cases tested only two were of value differentially. One was a fibroid of the uterus and the other an ovarian cyst. Both gave negative reactions. The earliest case to give a positive reaction had missed menstruation only four days. Another case eleven days post-partum reacted positively. Observations of toxemic cases with albumin in the urine and increasing blood pressure gave very slightly positive results with both the dialysis and optical methods. This confirmed the results obtained by Rubesamen in eclampsia cases. The test for pregnancy as worked out by Abderhalden might be considered a definite and reliable reaction.

Chronic Infections and Recovery with Immunity.—Dr. A. PARKER HITCHENS of Glenolden, Pa., read this paper. He stated that in the parenteral digestion of bacteria the bacterial proteins were digested by the specific ferments in order that they might be eliminated from the tissues. This effect sometimes failed while the poisonous action of the other part was always manifested. This being the case the suggestion forced itself upon them that there was a physical basis underlying the action of these two parts. That was to say the action of the poisonous part never failed because it was diffusible and the tissue offered no barrier to it, while the non-poisonous part was not diffusible, and under certain conditions the collection of cells in which it was located did not permit it to reach those cells capable of responding to its action. Accordingly, on the supposition that the molecule of the poisonous part was relatively small and that of the non-poisonous part

relatively large they might divide infections into three classes: (1) Those in which the bacteria were surrounded by a firm wall of inflammatory tissue so dense and so perfect that antibacterial ferments were unable to penetrate the bacteria. The non-poisonous part liberated by autolysis or by ferments within the focus of infection did not escape through the capsule and the resistance of the host was not increased. (2) Those in which the zone of inflammatory tissue was less dense and less perfect. The non-poisonous part of the protein molecule could not penetrate the barrier of inflammatory tissue, but specific ferments formed as a result of vaccination or auto-inoculation might penetrate in sufficient quantity to give positive therapeutic results. The staphylococcus furuncle was an example of this class. (3) Those in which the infecting bacteria were not surrounded by a zone of inflammatory tissue which inhibited the activity of the non-poisonous part and the resultant newly formed ferments came in contact with the bacteria without hindrance. The self-limited infections like typhoid fever were examples of this class. For obvious reasons infections belonging strictly to the first class could not be benefited by vaccine treatment. In the third class one might confidently expect much benefit from such treatment. Typical infections of the second class were no more difficult to treat than those of the third class. The diagnosis was made and the vaccine injected; as soon as the ferments had been produced in sufficient quantity the infection was overcome and the patient recovered. Such simple technique was effective in relatively few diseases, but one must not conclude that all other infections belonged to the first class; by far the great majority should be placed in the subvariety of the second class. Although they might react with little or no benefit to the mere injection of the vaccines, careful examination of other factors would reveal that with accessory methods of treatment positive results might be obtained.

Dr. VICTOR C. VAUGHAN of Ann Arbor, Mich., said that he and Dr. Wheeler had hit upon a method of splitting up bacterial proteins to get the poisonous and the non-poisonous portion. The poison was not destroyed by alcoholic solutions of potash 1/10 to 2/10 of one per cent. They had tried this and were able to split up colon, typhoid, and other pathogenic bacilli into poisonous and non-poisonous groups; they then tried the non-pathogenic organisms and found the same thing. The bacteria which produced the largest amount of protein poison was the B. prodigiosus. In round numbers it gave one hundred times as much poison per milligram as the anthrax bacillus. The conclusion they reached from this was that the infectious character of anthrax was not due to the poison it liberated, but to the capability of the anthrax bacillus growing in the tissues. They tried animal proteins, serum albumin, and serum globulin, and found the same poison. They also found poison in vegetable proteins, and as a matter of routine tested the non-poisonous parts, and to their surprise these gave at least a certain degree of immunity to the living germ. They had split edestin, which many claimed was a pure protein body, and got the poisonous constituent out of it. They went over a great many proteins and made the statement, subject to revision after more extended research, that all proteins contained a poisonous group. Of all the papers on experimental work produced within the last few years there were only two which appeared to be contradictory to this theory, one by Auer and Van Slyke, and one by Gibson, published in the *Philippine Journal of Science*. The work of White, Avery, and Wells seemed to point to the fact that the protein molecule did contain sensitizing groups. The Abderhalden test was a support to the theory of bacterial ferments and it was a biological law that when a living cell was stimulated by a foreign protein it tended to produce a ferment which digested that protein. If this were a law, further investigation might render protein sensitization of value in the prevention and treatment of disease. Every cell in the animal body must produce its own specific ferment; it could not receive and utilize its food in any other way. If one could educate the cell to produce a ferment which it had not produced, and he believed they did this with typhoid vaccination, the most reasonable explanation was that the body cells learned to digest typhoid bacilli. Dr. Vaughan said that he regarded the carcinomatous cell as so modified a cell that it produced specific ferments. The work done by J. W. Vaughan on cancer fitted in with this theory. He sensitized animals with cancer residue or the whole cancer cell. This led to an increase in the large mononuclear cells in which ferment was found which, when injected directly into cancerous tissue, produced in the patient all the symptoms of anaphylactic shock. He had experimented with this ferment and was inclined to say at present that the poison in its purest form was not a protein, whether it was the histamine of Barger and Dale or some closely related substance he did not know. He had made a great many experiments with the non-poisonous part of the tubercle bacillus and while he was not ready to publish his experiments thought he might say that the non-poisonous part of the tubercle bacillus did not protect guinea pigs in any way from inoculation with tubercle bacilli. He thought it was harmful, for those treated died quicker than the others that were not so treated. In a great many guinea pigs, in the later stages of tuberculosis, he had injected the non-poisonous part and within one-half hour the temperature began to fall and continued to fall for two or three hours. This hastened the splitting of the tubercle bacilli. With rabbits the non-poisonous part apparently emphasized the resistance to the tubercle bacillus, but rabbits were irregular in their reaction toward the tubercle bacillus, so they could not draw any conclusions. The non-poisonous portion of the tubercle bacillus was not harmful if given to rabbits intravenously.

Blood Platelets and Immunity.—Dr. GERALD B. WEBB of Colorado Springs, Col., presented this paper. He reviewed the history of blood platelets and showed that they probably contained or supplied opsonin. Blood platelets were found to be increased by an altitude of 6,000 feet, also by hyperemia of the marrow, and in carbon monoxide poisoning. Blood platelets were always increased in tuberculosis. The author found them decreased in measles during the attack. They were found increased in pellagra. Preliminary experiments suggested the possibility that the blood platelets could sensitize tubercle bacilli.

The Influence of Vaccine Therapy on Blood Morphology.—Dr. FREDERICK E. SONDERN of New York City said that the cause of vaccine therapy might be furthered by observing the relation between the administration of vaccines and the leucocyte count, the differential count, and the exact degree of existing anemia. No work had yet been done with this point particularly in view. In those acute general infections in which vaccine therapy had been supposed to be of benefit, blood examinations had shown hyperleucocytosis with a decreased polynucleosis. Even fatal cases showed a slight improvement in the blood picture with the use of vaccines. In reviewing the subject of vaccine therapy in acute general infections it was necessary to state that while it had met with some success in practice, it was still open to question from a theoretical standpoint, and should be considered as purely experimental. Autogenous bacterial vaccines had proved of value in cases of localized chronic infection. These were now used without the determination of the opsonic index. Further investigation should be given to those cases in which vaccine therapy was not successful. The successful use of vaccine therapy in chronic local suppurative processes seemed to cause an increased leucocyte count, a decrease in the relative lymphocytosis, and improvement in the anemia. In cases aggravated by vaccine treatment the leucocyte count was lower than before treatment, the relative lymphocytosis more marked, and the anemia increased. Further investigation was necessary to determine whether these blood changes were constant, and whether they might be taken as an index of the utility of vaccine therapy.

Dr. WILLIAM EGBERT ROBERTSON of Philadelphia, Pa., said that he had been interested in the clinical phase of chills in typhoid fever. The chill seemed to have a beneficial effect and was usually followed by a lower temperature, going to normal in a few hours and gradually rising again. Usually convalescence occurred. In the course of typhoid fever there was a very distinct lowering of the polymorphonuclears with a relatively greater increase in the lymphocytes. Giving the bacterins in large doses when it was possible to make a clinical impress on the case gave the same results, seeming to indicate that the cause of the chill was essentially acute bacteriolysis.

Vaccine in Relation to Mouth Infection.—Dr. JOSEPH HEAD of Philadelphia, Pa., read this paper, in which he contended that the treatment of mouth infections should include the removal of all infecting masses by local surgical treatment, and application of mouth washes, and a more or less extensive treatment with vaccines. As mouth washes a one per cent. solution of hydrogen

peroxide made slightly alkaline, or sodium silico fluoride in aqueous solution of a strength of 0.61 per cent. might be recommended. Their effect, since they were not germicidal, might possibly be due to a sensitization of the bacteria, thus allowing a more effective action of the body ferments. In connection with local treatment the vaccines gave excellent results. A stock vaccine was used containing the bacteria most frequently found in forty-two cases examined. The writer gave the technique for removing material from infected pockets for the preparation of an autogenous vaccine. The course of the treatment should be regulated with great care, according to the presence or absence of reaction. The blood count was of interest and might prove of value as a guide to dosage. The writer reported cases which showed the value of vaccine treatment in mouth infections.

Complement Fixation Tests in Infective Deforming Arthritis and Arthritis Deformans.—Dr. T. W. HASTINGS of New York City presented this communication in which he described the method by which the complement fixation test was applied to cases of infective deforming arthritis and arthritis deformans in order to determine, if possible, the etiological factor of the disease. The antigens used included various strains of streptococci, other organisms isolated from cases of arthritis, and polyvalent gonococcus antigens. A Wassermann test was made in every case. Of 43 cases of arthritis, 25 of deforming arthritis gave positive complement fixation and positive Wassermann tests; 19 cases of arthritis deformans gave positive tests, 17 reacting positively to streptococcus viridans, and four to a polyvalent gonococcus antigen. The 26 control cases, not arthritis, were with very few exceptions negative to complement fixation tests for streptococcus viridans. The results indicated that the streptococcus viridans was the probable causative agent in many cases of arthritis deformans. About 40 per cent. of cases of arthritis deformans should be considered as chronic infective deforming arthritis. The clinical manifestations of this condition were rarely due to gonococcus infections. When a positive reaction occurred with both a streptococcus and a gonococcus antigen, the reaction to the former should be considered the indicator of the causative agent, as there was often a latent infection with the latter in the genitourinary tract.

Comparative Wassermann Cobra, and Globulin Tests in Syphilis, with Report of One Hundred and Five Cases.—Dr. WILLARD J. STONE of Toledo, Ohio, presented this paper. He outlined in detail the technique of the cobra venom test and of Noguchi's butyric acid test for increased globulin, and stated that the comparative work upon the Wassermann and cobra venom reactions in syphilis had given very similar results. Of 105 cases examined by the author there was marked uniformity in these tests. There were some differences in outcome, but the discrepancies were not great. The result of the globulin test differed from the other two reactions in a larger percentage of cases.

Dr. JOHN A. KOLMER of Philadelphia, Pa., said that in a certain percentage of cases the cobra venom test was slightly more delicate than the Wassermann reaction, but not when active serum was used. They had been using antigens reinforced by the addition of pure cholesterin for the Wassermann reaction and had not been able to convince themselves that the cobra venom test was as delicate as the Wassermann test thus reinforced. Cholesterin antigens were possibly hypersusceptible and required close controls. Since using cholesterin antigen they had found correct positive results in tertiary syphilis in a larger percentage of cases than with the venom test, though he believed that the venom test did have a distinct value in the diagnosis of lues in certain stages. In the primary stage hypersensitiveness of the red blood cells rendered the venom test of little value in the diagnosis of syphilis.

Dr. RICHARD WEIL of New York City said that the observations of Kober showed that, in addition to the production of antihemolysis when venom was injected into animals, there was also a change in the red blood cells. He had tested a considerable number of hemolysins in order to see whether under any other conditions similar resistance developed on the part of body cells. It was found that the red blood cells of luetic individuals showed an increased resistance to cobra venom. In regard to the constancy of this fact, on which its value as a diagnostic measure depended, they had not made a sufficient number of tests to show anything definite. Other seemed to have established the fact that it was fairly characteristic. While under given conditions the speaker believed that the cobra venom test might not compare equally with the Wassermann reaction it would in a number of cases show positive results in luetic cases in which the Wassermann would be negative. It was certainly true that the Wassermann showed a considerable larger percentage in the total of positives.

Dr. JOHN A. KOLMER of Philadelphia, Pa., said that he also wished to make the point that the protein reaction in cerebrospinal fluid also fell far short of the Wassermann reaction in the diagnosis of syphilis of the cerebrospinal system. The globulin test was uniformly positive in various types of inflammation of the spinal meninges. Hence they used the globulin test to differentiate tuberculous meningitis from the so-called serous meningitis or meningismus. In the latter the protein reaction was uniformly negative, whereas in tuberculous meningitis it was uniformly positive.

A Note on the Preparation of Bacterial Vaccines.—Dr. WILLARD J. STONE of Toledo, Ohio, read this paper. He stated that some of the reactions following the administration of bacterial vaccines were due to the presence of extraneous proteins, derived either from the culture media or the soluble excretory products of the bacteria. To do away with extraneous proteins all bacterial suspensions used in the preparation of vaccines, with the exception of such fragile organisms as the gonococcus and pneumococcus, were washed with a high speed centrifuge until the supernatant salt solution no longer gave the biuret reaction. In standardizing the vaccines a suspension of living washed organisms was used and Dr. Spooner's method of counting employed.

Dr. A. PARKER HITCHENS of Glenolden, Pa., said that the effect of peptotoxins present in bacterial vaccines was relatively slight because the quantity was very small. When injecting large animals for the preparation of antibacterial sera enormous doses of the germs were administered and in such cases they saw the possibilities of peptotoxin. Formerly when it was the practice to inject unwashed bacteria they were compelled to use as a maximum dose a quantity less than 1/1000 the amount that they could now use, since they washed the bacteria even with very large doses symptoms af anaphylaxis were not observed.

Dr. JOHN REICHEL of Glenolden, Pa., related that in attempting to immunize cattle against contagious abortion with suspensions of dead bacilli of contagious abortion they had observed that when unwashed bacilli were injected intravenously severe and unusual symptoms followed almost immediately. It was subsequently shown that these symptoms were due to peptotoxin. They had also precipitated peptotoxin with absolute alcohol, and it was shown that the substance remained unchanged after boiling, and that it could be kept almost indefinitely.

Dr. JOHN A. KOLMER of Philadelphia, Pa., said that it had been their custom to wash vaccines grown on ascitic agar or blood agar, but not those that were made with organisms that would grow on ordinary nutrient agar. Dr. Kolmer also emphasized the necessity in counting the bacteria with a counting chamber of carefully filtering the dye before it was put into the chamber.

Dr. STONE said it was necessary to wash all bacterial suspensions grown upon nutrient agar. They had found that such suspensions would give a very marked biuret test after centrifugation. All agar-grown bacteria in salt solution suspensions would give nearly as strong a biuret test as suspensions of bacteria grown upon serum or in bouillon.

Autoserotherapy; also the Therapeutic Use of Inactivated Pus and the Value of Tuberculins in Serous Cavities.—Dr. WILLIAM EGBERT ROBERTSON of Philadelphia, Pa., read this paper, in which he gave an extensive review of the work in autoserotherapy from the time of its introduction to the present. As applied to pleural effusions of the serous or serofibrinous type, he said, it had proven of value in proportion to the incipiency of the tuberculous lesion. The injection of old tuberculin following the fractional withdrawal of fluids from the pleural cavity had given excellent results, especially in cases of long standing. Similar use of bacillen emulsion had proven less satisfactory. The reinjection of inactivated purulent exudates possessed some therapeutic value, although in general the results had not been uniform. Though inactivation destroyed the infectivity of the exudate, it was not necessarily sterile, so that it might possess the properties of a bacterin and also of a leucocyte extract.

Dr. C. MORTON ILLMAN of Philadelphia, Pa., said he

had had the opportunity of seeing many of these cases that Dr. Robertson had reported from the clinical standpoint, and had been struck with the marked regularity of the results. There was through the entire series much that was encouraging in their bacterin work. In the very beginning of their work with bacterial vaccines in America they had issued a warning against the promiscuous use of bacterins and other toxic products and they were beginning to recognize that the things they had feared from the toxic effects of bacterins were coming to pass. Throughout this meeting thus far one thing stood out clearly and that was that the cellular living tissues did react to the call for the production of digestive ferments to any one or a dozen active infectious agents or their products. He believed Dr. Vaughan's hypothesis was a reasonable fact.

The Experimental Basis of Tuberculin Therapy.—Dr. GEORGE BURTON GILBERT of Colorado Springs, Col., presented this paper, in which he reviewed the work done with tuberculin, and stated that it was evident that a sound experimental basis for the use of tuberculin had not yet been found. The writer described his experiments with two series of guinea pigs and concluded that the results of the work indicated that the tuberculin treatment given neither cured nor checked the course of the disease to any important extent.

Tuberculin Therapy: Its Present Imperfections and Future Improvements.—Dr. F. M. POTTENGER of Monrovia, Cal., read this paper. He declared that the fact that tuberculin had not succeeded in producing immunity was not an indication that it did not cause healing, for definite focal stimulation and healing had been seen to follow the administration of a tuberculin which had failed to produce a high degree of experimental immunity. Many of the faults ascribed to tuberculin were due to lack of skill in administration. Its value could not be estimated from the results obtained from its use upon experimental animals as the natural resistance of such animals was not comparable to that of human beings. Progress in tuberculin therapy depended upon an improvement in both the laboratory production and the clinical application. Work should be done in the laboratory in determining more exactly the constituents of the various tuberculins and in producing tuberculins of a definite standard.

Dr. GERALD B. WEBB of Colorado Springs, Col., said he did not think anyone could work in Wright's Clinic and not be impressed that tuberculin did some good. In tuberculin therapy it seemed that they had an instance in which it did not seem possible to completely prove the therapeutic value by animal experimentation.

Dr. JOHN REICHEL of Glenolden, Pa., said that the laboratory of the Pennsylvania State Livestock Sanitary Board was in possession of two cultures of tubercle bacilli, one of the human type without virulence for experimental animals, and another, a bovine culture, which was highly virulent, for experimental animals and for cattle. Tuberculins prepared with each of the two strains proved equally satisfactory in the tuberculin test of infected cattle. This would tend to show that tuberculins were not likely to vary so far as virulence was concerned, since the reactions with each of the strains was equally strong.

Dr. JACOB BRONFENBRENNER of Pittsburgh, Pa., called attention to the fact that inherent properties of different cultures of tubercle bacilli might be responsible to a certain extent for discrepancies in the results obtained by different investigators, as it was well known that pathogenic organisms were very apt to change their biological properties when cultivated on artificial media. Indeed, it seemed that the greater the difficulty with which the organism adapted itself to the artificial media, the more radical the changes it underwent when once cultivated. The reason for this seemed to be that in such cases the organism must markedly change its metabolism in the process of adaptation to the medium, if it was to become at all adapted. The tubercle bacilli seemed to be a striking exception to this rule as the oldest strains seemed to retain their pathogenicity. The speaker said he had been working with the tubercle bacilli cultivated by Besredka and he entertained the hope that this new tuberculin might be very useful as antigen in the complement deviation test for the diagnosis of tuberculosis as well as for treatment of the disease. In his diagnostic work he had obtained 98 per cent. of positive results in different cases of tuberculosis and only eight per cent. of positive results among non-tuberculous subjects. It was quite apparent that in many ways the tubercle bacilli of Besredka had acquired distinct properties. It seemed quite important that those who reported favorably on their experiments of tuberculin therapy should give as completely as possible the history of the tubercle bacilli used and the minutest details of their preparation.

Dr. F. M. POTTENGER of Monrovia, Cal., said that he wished to make his attitude toward the laboratory clear. He who studied the disease exclusively would fail and likewise he who devoted his attention entirely to the patient; but by recognizing that both must be treated the greatest success would be attained. There was quite a difference between experimental tuberculosis and tuberculosis as they knew it clinically. With reference to the treatment of tuberculosis with tuberculin, one of the most important principles to remember was that the administration of this remedy was an individual matter. A large dose for one patient and for one pathological condition was a small dose for another, and a dose might be exceedingly large if the patient had not been prepared for it, and yet be a small one when this tolerance had been established. Small doses given infrequently increased the patient's sensibility, while large doses given at the right time decreased hypersensitiveness and increased the patient's tolerance, but it must be remembered that large and small were purely relative matters.

Presidential Address.—Dr. GERALD B. WEBB of Colorado Springs, Col., made this address, taking as his subject "The History of Immunity." After dwelling on the life and work of Jenner and Pasteur, the speaker said that they were naturally proud to have with them in this country the one who took the next step forward as an immunologist, Thebald Smith, who showed, in 1886, that immunity from hog cholera could be produced by the inoculation of bacterial products. In 1890 came the discoveries of Behring and Kitasato on tetanus and diphtheria, and their antitoxins for these diseases which found ready acceptance with the profession. Koch, with his products of dead tubercle bacilli, was the first to treat disease with what later became Wright's conception of vaccines. Disastrous results followed Koch's experiments, but it was otherwise with Wright, who might undoubtedly be regarded as the founder of vaccine therapy. In his own words, "The fundamental principle of vaccine therapy, as I conceive it, is to exploit in the interest of the infected tissues the unexercised immunizing capacities of the uninfected tissues." After paying a fitting tribute to the work of Wright, the speaker said that after eight years' experience with vaccine therapy, and with the passing of the early enthusiasm, it was well to review briefly its present status. Ehrlich, fresh from his recent triumphs in immunology, expected that within the next five years advances in chemotherapy might lead to successful treatment of bacterial diseases in a manner similar to his cure of spirilla infections. Until the predicted discoveries might be made, Wright's vaccine treatment and the improvements which were rapidly developing seemed to be the best treatment at hand. Time had shown that the method was of undoubted value in infections due to many bacteria. On the whole they had to record more failures than successes. One could not but feel, however, that many of the failures must be due to the inability of the protective substance to reach the foci of infection. This had been especially urged by Wright and more recently by Hitchens. The brilliant work of Vaughan, the American pioneer in immunology, seemed destined to aid them greatly. The elimination of the toxic group of the protein molecule had already borne fruit, and the gratifying results of Rosenow, in his employment of autolyzed products of the pneumococcus in pneumonia, seemed to affirm his theory. It was yet too early to know how much better would be the employment of sensitized bacterins, but the theory of their usage was sound. Dr. Webb then referred to the work of Flexner, Swift, and Ellis, and, in conclusion, said he largely agreed with Wright that the physician of the future would be an immunologist, and, he would also add, a hygienist. The hygienist and the immunologist must work closely together, and Pasteur's prophecy that it was within the power of man to rid the world of infectious diseases would be eventually fulfilled.

The Relation of Parenteral Digestion to Immunity.—Dr. VICTOR C. VAUGHAN of Ann Arbor, Mich., made this address, in which he stated that cells were com-

posed of protein and required protein for their metabolic processes. The protein molecule as such was of no value, that was, digestion must take place before absorption or utilization could occur. In enteral digestion the cleavage was normally complete. Toxic products were further degraded as fast as they were formed. In parenteral digestion an analogous cleavage occurred, but the toxic products were carried throughout the organism before further splitting could convert them into simpler non-toxic fragments. All cells were provided with the necessary mechanism to insure a degree of cleavage. This power resided in the ferments elaborated by the cell. Not every cell could utilize the same fraction of the protein complex. Therefore, a selective action was manifested, each type of cell producing a definite type of ferment capable of acting upon the material supplied in such a way that it could become incorporated into the cell body. This conclusion reached by reasoning had been demonstrated by experiment upon digestion in unicellular organisms, in bacteria, and in leucocytic digestion. As a defense against foreign proteins, as, for instance, invading bacteria, cells elaborated two kinds of ferments, group and specific. The group ferments were normally present in the blood and tissues of all animals. They were, within limits, general proteolytic ferments, but differed in kind, in amount, and in efficiency. Specific ferments were called forth in direct response to the introduction of a foreign protein and were capable of degrading that protein only. The production and presence of these general and specific proteolytic ferments had a very important bearing, Dr. Vaughan said, upon the phenomenon of immunity.

Dr. Jacob Bronfenbrenner of Pittsburgh, Pa., said he would like to know whether a substance like tetanus toxin, for instance, was considered primarily toxic or whether it was simply so easily digested by ferments that the toxicity did not require any incubation period to show itself.

Dr. Vaughan replied that, of course, the word "toxin" had taken on a specific meaning. Toxin was a substance which produced an antibody when injected into animals. It might be said that all toxins were poisons, but not all poisons were toxins. The protein poison was not a toxin; it did not produce any antibody. Whether the toxins were ferments or not Dr. Vaughan said he could not say. If it could be proved that the toxins were ferments the whole subject would be cleared up. Abderhalden had shown by his optical method that the toxins did split up proteins. That was as far as they had gone. The most rational explanation was that when diphtheria toxin got into a child's body or when it was injected into a guinea pig it split up the protein of the body and set the protein poison free. It was the protein poison that killed. He did not say that this had been demonstrated, but toxins certainly were closely related to the ferments. They acted in very small amounts, in high dilution, and they were destroyed by high temperatures. The toxin would act in dilutions so great that they did not give the biuret test. That was a still further indication that it was a ferment. Dr. Vaughan said he had an antipathy to calling these ferments antibodies; one might as well call pepsin anti-meat, because it digested meat.

Dr. James W. Jobling of Nashville, Tenn., said that Dr. Vaughan had left little to be said. Dr. Vaughan had first aroused his interest in this subject and caused Strouse and himself to study the cleavage products of proteins when acted upon by the leucoprotease of human leucocytes. They were able to obtain toxic substances in this manner, and by fractionating the products they found that the toxins were present in the proteose fraction. They were unable to say whether there were actually primary proteases, or merely substances which were carried down mechanically with this fraction, though the ease with which they might be made non-toxic by the further action of trypsin and leucoprotease indicated that they were primary proteoses. They had been inquiring into the methods used by the body in preventing the formation of these toxic substances and had found that the antitryptic action of the serum was due to the unsaturated fatty acid radicals of the lipoids. These lipoids might be extracted by chloroform and when the chloroform extract was properly treated the anti-ferments might be obtained almost quantitatively. The serum treated with an excess of chloroform lost entirely its antitryptic action and it also lost its activity if treated with an oxidizing agent as iodine. Guinea-pig serum from which the anti-ferment had been removed became toxic for other animals of the same species, and this applied to all sera which they had tested. In the course of their work they had observed that bacteria, kaolin, and other substances would remove the antiferments from the serum and render it toxic. This was important in view of the work done with the so-called anaphylotoxins, and also suggested the possibility of their being a true autointoxication due to local or generalized absorption of antitrypsin. It was also possible that some of the metabolic disturbances leading to cirrhosis of the organs, etc., might have their origin in a disturbed ferment. When Dr. Vaughan stated "that live bacteria ingested proteins" did he mean that the bacteria took up and assimilated native proteins, or did he use the term in a more general sense and include the lower cleavage products?

Dr. Vaughan replied that he did not believe that any cell took a protein and absorbed it as a whole, but it might absorb it without splitting it far enough to liberate the poisonous group. He thought they could claim pretty good evidence that no cell could take a foreign protein and build it directly into its body. Dr. Vaughan also discussed the relation between the antitrypsin and the trypsin of the blood. Here lay a most important field of investigation. The balance between the proteins present in the blood and the proteolytic ferments must be something which was capable of the nicest kind of adjustment. From what he had said one could readily see that while he believed that the ferments of the body destroyed the invading organism life might be saved by an abundance of the antibody preventing the too rapid action of the substance which was destroying the bacteria.

Demonstration of a Simple Method of Making Cultures from Tissues, and Its Application in Arthritis Deformans.—Dr. Edward C. Rosenow of Chicago, Ill., presented this paper, in which he stated that up to the present time there had been no systematic bacteriological examination of the tissues of the body during infection. The author had devised apparatus which was efficient for this purpose and which he described fully. In preparing cultures from tissue emulsions, it was advisable to plant the emulsion deep in rather tall tubes of ascitic dextrose agar. With this method of planting there were afforded all the gradations between aerobic and anaerobic conditions, and growth was obtained from organisms ordinarily hard to cultivate. The method described had proven particularly successful in culturing cases of arthritis deformans, streptococci, staphylococci, and organism resembling *Bacillus mucosus* and *B. welcheii* had been isolated from fifty-four cases. Cultures made from the joint and also from the lymph gland draining the joint had frequently yielded the same organism. This fact would be of service in studying arthritis deformans. It would be of interest to discover how this microorganism acted upon the body to produce this form of disease.

Dr. Victor C. Vaughan of Ann Arbor, Mich., said he had followed Dr. Rosenow's work and believed it to be of the greatest importance scientifically and practically.

The Intraspinal Treatment of Syphilis of the Central Nervous System with Salvarsanized Serum of Standard Strength.—Dr. Hanson S. Ogilvie of New York City read this paper. He stated that in order to reach the diseased areas in syphilis of the central nervous system, intraspinal treatment as introduced by Swift and Ellis was strongly recommended. The author based his preparation of salvarsanized serum upon the method of Swift and Ellis, but he prepared his serum by adding salvarsan and subsequently heating *in vitro* so that the strength of the curative agent might be regulated. Thus he obtained a serum of known salvasan content. With a carefully perfected technique of preparation and administration of the serum there was little danger of severe reaction. In 50 per cent. of the treatment there was no reaction of any kind beyond a slight temporary weakness. It was important that the dosage should be small—within 1.0 mg. The results of the cases studied demonstrated that the laboratory evidences of active syphilis, as shown by the Wassermann reaction, in both the blood and spinal fluid, and the cell count, and globulin content, were reduced to a greater or less degree in every instance. In the majority of cases there was marked clinical improvement. The method was of interest because it furnished the means of giving salvarsan in small doses intraspinally without danger to the patient.

State Medical Licensing Boards.

STATE BOARD EXAMINATION QUESTIONS.

TENNESSEE STATE BOARD OF MEDICAL EXAMINERS.

May 4 and 5, 1914.

(*Continued from page 866.*)

MATERIA MEDICA.

1. Give antidotes for arsenic, carbolic acid, strychnine, and chloral hydrate.
2. Describe the physiological action and give the therapeutic use of digitalis.
3. Differentiate between apoplexy and opium poisoning.
4. What is ergot? What are its most pronounced physiological actions?
5. Give indications for the use of the following: nux vomica; arsenic; belladonna.
6. What is mercury? Source; physical properties; uses; dosage? Remarks.
7. Give five drugs and their incompatibles.
8. Name two acids, two alkalies, and two mineral poisons. Symptoms, cause of death in, and their antidotes.

CHEMISTRY.

1. Define the following: allotropism; endosmosis; alloy; amalgam.
2. Select the five most important reagents for a uranalysis outfit, and state why you select each.
3. What is the explanation of souring and curdling of milk? How is soured milk supposed to prolong life?
4. What are ptomaines? Name some of the best known ptomaines.
5. Give the chemical names and formulas of the following: sugar of lead; flowers of sulphur; blue vitriol; white lead; red lead; baking soda; quick lime; lime water; lime stone; blue stone.
6. Point out the analogy between marsh-gas (paraffin) and the benzine series of hydrocarbons. Name two prominent members of each group.
7. Describe a test for (*a*) albumin, (*b*) sugar, (*c*) pus, (*d*) indican, (*e*) chyle.
8. How would you test milk for impurities? For adulterants?

PATHOLOGY.

1. Explain why and how obstructive disease of the coronary arteries causes myocardial degeneration.
2. What is the pathology of acute appendicitis, going on to suppuration?
3. Discuss primary, concurrent (or mixed), and terminal infections.
4. Give the pathology of acute anterior poliomyelitis.
5. In the case of a woman, who a few days after childbirth, is suddenly taken with dyspnea and cardiac syncope and quickly dies, describe the pathological conditions you would expect to find post-mortem.
6. Describe the appearance of the heart in an advanced case of mitral stenosis. What are the results of mitral stenosis on other organs? Explain how these results are brought about.
7. What part of the spine is affected in Pott's disease? Describe the pathological changes taking place in the bone in Pott's disease.
8. What is an "autogenous vaccine?" On what principle or principles is vaccine therapy based?

ANSWERS.

MATERIA MEDICA

1. Antidote for *arsenic* is freshly prepared solution of ferric hydroxide; for *carbolic acid*, sodium sulphate, or alcohol; for *strychnine*, tannic acid; for *chloral hydrate*, solution of potassium hydroxide, or strychnine.

2. DIGITALIS. *Physiological action:* It is a gastrointestinal irritant, it slows the rate of the heart, prolongs diastole, increases the force of the heart, it contracts the blood-vessels, and causes a rise in blood pressure, it also acts as a diuretic.

Therapeutic use: Digitalis is indicated in diseases of the heart: (1) when the heart action is rapid and feeble, with low arterial tension; (2) in mitral lesions when compensation has begun to fail; (3) in nonvalvular cardiac affections; (4) in irritable heart, due to nerve exhaustion. Digitalis is contraindicated in diseases of the heart: (1) in aortic lesions when uncombined with mitral lesions; (2) when the heart action is strong, and arterial tension high. Digitalis is also a diuretic; and it is also used in some forms of nephritis, exophthalmic goiter, pneumonia, chronic bronchitis, etc.

3.—

APOPLECTIC COMA.	OPIUM POISONING.
Deep coma; sudden onset. If any injury, only a scalp wound.	Can be aroused unless very deep.
Pupils unequal or dilated. Contracted in hemorrhage into the pons.	Pupils contracted to pinpoint size.
Pulse full and slow, often arteriosclerotic high-tension pulse.	Pulse rapid, may be irregular.
Respiration slow and irregular.	Respiration very slow—may be 6 to 8 per minute.
Temperature higher on paralyzed side, but lower in rectum.	Normal or subnormal.
Urine contains trace of albumin, but may be same as in uremia.	Normal.
Hemiplegia with convulsions on one side.	No hemiplegia.

4. Ergot is the sclerotium of the *Clavicceps purpurea.* It should be moderately dried, preserved in a close vessel, and a few drops of chloroform should be dropped upon it occasionally. It is not fit for use if more than a year old.

Ergot stimulates and causes contraction of involuntary muscle fibers, hence it is a vasoconstrictor, hemostatic, and oxytocic. It is also a cardiac sedative, it is an emmenagogue.

5. *Indications for the use of nux vomica:* As a general tonic or bitter; in indigestion, cardiac depression, impaired peristalsis, pneumonia, phthisis, amenorrhea, dysmenorrhea, impotence, some forms of paralysis, chorea, epilepsy, neuralgia, alcoholism, and urinary incontinence.

Indications for the use of arsenic: In stomach disorders, bronchial and pulmonary affections, diabetes, diarrhea, anemia and chlorosis, chorea, malaria, and chronic skin diseases.

Indications for belladonna: To relieve pain, relax spasm, check sweating, as a mydriatic, to check griping of purgatives; in asthma, to check fevers, in heart disease, shock and collapse, acute coryza, urinary incontinence, chordee, low delirium of fevers, mania, alcoholism; as an antigalactagogue, spasmodic cough.

6. *Mercury* is an absorbable metal. Its action on the circulation: In small doses it has a tonic effect; in larger doses it diminishes the number of red-blood cells, impoverishes the blood, and thus upsets the digestion, and disturbs the general nutrition of the body.

It is prepared from cinnabar by distilling it in a current of air. It is a bright metallic liquid, volatile, very heavy, insoluble in water, and readily unites with many metals to form amalgams.

Preparations and doses: Emplastrum hydrargyri; Hydrargyrum cum creta, dose. 4 grains; Massa hydrargyri, dose, 4 grains. Unguentum hydrargyri; Unguentum hydrargyri dilutum; Hydrargyri oxidum rubrum; Unguentum hydrargyri oxidi rubri; Hydrargyri oxidum flavum; Unguentum hydrargyri oxidi flavi; Oleatum hydrargyri; Hydrargyri chloridum corrosivum, dose 1/20 grain; Hydrargyri chloridum mite, dose (laxative), 2 grains; (alterative) 1 grain; Pilulæ catharticæ compositæ, dose 2 pills; Hydrargyri iodidum rubrum, dose, 1/20 grain; Liquor arseni et hydrargyri iodidi, dose 1½ minims; Hydrargyri iodidum flavum, dose, 1/5 grain; Liquor hydrargyri nitratis; Unguentum hydrargyri nitratis; Hydrargyrum ammoniatum; Unguentum hydrargyri ammoniati.

Uses: "Mercurials (especially the bichloride) are extensively used for antiseptic purposes in surgery and midwifery. The acid solution of mercuric nitrate is employed as a caustic for warts, chancroids, mucous patches, etc., and citrine and red precipitate ointments as stimulating applications to ulcers and sores. Mercurial ointments and washes are very serviceable in the treatment of parasitic affections, and also in a variety of other skin diseases, as well as in ophthalmo-

logical practice. Internally blue mass and calomel are largely employed as purgatives, and the latter is a good intestinal antiseptic. It is used in serous and other inflammations, and both it and the bichloride have been given in diphtheria. The most important use of mercury is in the treatment of syphilis. In order to secure the best results in this disease it should be commenced early and continued for a considerable time after all symptoms have disappeared. In tertiary syphilis it is commonly combined with the iodides. *Modes of administration of mercurials:* By the mouth; endermatically; by inunction; hypodermatically; intravenous injection; fumigation; inhalation; baths."—(Wilcox's *Materia Medica.*)

7. *Incompatibles of colocynth:* Alkalies, ferrous sulphate, lead sulphate, lime water, mercuric chloride, silver nitrate; of *copaiba:* Mineral acids, caustic alkalies, calcium hydrate, magnesia, water; of *creosote:* Acacia, albumin, nitric acid, oxidizers, and salts of copper, iron, gold and silver; of *aconite:* Acids, alkalies, hot water; of *alum:* Alkaline hydrates, borax, carbonates, galls, kino, lead acetate, lime water, magnesia, magnesium carbonate, mercury salts, phosphates, tartaric acid, potassium chlorate.—(From Potter's *Materia Medica.*)

18. *Hydrocyanic acid poisoning. Symptoms:* "Its action is always rapid. Relatively small doses cause an immediate sense of constriction of the throat, followed in one to two minutes by sense of pressure in the head, vertigo, confusion of intellect, and loss of muscular power. The pulse is quick, the respiration slow and stertorous. Tetanic convulsions and involuntary discharges of urine and feces occur, followed by paralysis. Death follows in from two hours to two days from asphyxia. When large doses are taken no subjective symptoms are observed. The patient loses consciousness in less than one minute. There is a short convulsive seizure, usually accompanied by evacuation of feces, after which the patient lies perfectly still, with no sign of life, save an almost imperceptible pulse and infrequent spasmodic respiratory efforts, in which inspiration is short and expiration protracted. Death follows in from five to twenty minutes."—(Witthaus' *Essentials of Chemistry and Toxicology.*) Death is due to paralysis of the respiratory center and of the motor ganglia of the heart. There is no antidote.

Symptoms of poisoning by oxalic acid: "The sour taste of the acid is rapidly followed by a burning pain, increasing in intensity, in the mouth, throat, and stomach, and persistent vomiting of a dark, 'coffee-ground' material. The pulse becomes small and imperceptible, and the patient dies in collapse, preceded frequently by convulsions, within half an hour. If the case be prolonged, swallowing becomes very difficult and painful; there are numbness and tingling of the skin; twitchings of the facial muscles; convulsions, frequently tetanic; delirium, and lumbar pain. Death occurs in some cases within three to ten minutes, sometimes almost immediately, and in some cases it is delayed for several days."

Cause of death, paralysis of nerve centers. Antidote, syrup of lime.

"The symptoms presented in cases of *poisoning by potash and soda* are so similar that one description will do for both. There is burning pain during swallowing, and an acrid, caustic taste. If the fluid penetrates to the stomach, there is persistent burning pain. Vomiting may or may not occur. When it does, the vomitus will usually be brown in color; it may or may not contain blood, and will simulate very closely in appearance that found after the taking of any of the strong acids. *Ammonia* presents rather more violent symptoms in proportion of its strength than does potash or soda, and on account of the irritating quality of its fumes symptoms due to its inhalation are very marked."—(Dwight's *Epitome of Toxicology*).

Cause of death is generally starvation due to stenosis of esophagus, or stomach, or pylorus or intestine. Antidote is vinegar, citric acid, or tartaric acid.

SILVER NITRATE POISONING. *Symptoms:* Pain; vomiting of white, cheesy matter, which becomes black in the sunlight; cramps; purging; depression; convulsions; coma or collapse. *Antidote:* Solution of sodium chloride.

The *symptoms of acute lead poisoning* are: "Metallic taste; dryness of the throat; thirst; severe colicky abdominal pains, referred particularly to the umbilical region, and relieved by pressure; pulse very feeble and slow; great prostration; constipation; urine scanty and red; violent cramps; paralysis of the lower extremities; convulsions, and tetanic spasms."

The antidotal treatment consists in administering "magnesium sulphate, which brings about the formation of the insoluble lead sulphate, while the purgative action of the magnesia is also useful. It should be preceded by an emetic, or by the use of the stomach tube."

CHEMISTRY.

1. *Allotropism* is the capability of a substance to assume different physical properties while retaining the same chemical properties.

Endosmosis is osmosis toward the interior of a vessel or cavity. (*Osmosis* is the passage of a fluid or solution through a membrane or other porous substance.)

Alloy is a substance composed of two or more metals.

Amalgam is an alloy containing mercury.

2. (1) Dilute acetic acid (to acidify alkaline urines before testing for albumin). (2) Nitric acid (to test for albumin and for bile pigments). (3) Fehling's solution (to test for sugar). (4) and (5) Hydrochloric acid and chloroform (to test for excess of indican).

3. *Souring of milk* is due to the formation of lactic acid and succinic acid from the lactose by microorganisms. *Curdling of milk* is due to the presence of rennin and lactic acid. Soured milk is supposed to prolong life by reducing intestinal putrefaction.

4. *Ptomaines* are basic nitrogenized compounds produced from protein material by the bacteria which cause putrefaction. *Examples:* Putrescin, cadaverin, cholin, neuridin, amantin, muscarin, mydalein.

	CHEMICAL NAME	FORMULA
Sugar of lead	Lead acetate	$Pb(C_2H_3O_2)_2$
Flowers of sulphur	Sublimed sulphur	S.
Blue vitriol	Cupric sulphate	$CuSO_4$
White lead	Lead carbonate	$(PbCO_3)_2$. PbH_2O_2
Red lead	Plumboso-plumbic oxide	Pb_3O_4
Baking soda	Monosodic carbonate	$NaHCO_3$
Quick lime	Calcium monoxide	CaO
Lime water	Calcium hydroxide	CaH_2O_2
Lime stone	Calcium carbonate	$CaCO_3$
Blue stone	Cupric sulphate	$CuSO_4$

6. The paraffin and benzene series are somewhat similar in that they both form halogen derivatives and also alcohols, aldehydes, acids, ketones, nitro compounds and amido compounds.

Two members of the paraffin group—Methane and ethane.

Two members of the benzene group—Benzene and toluene.

7. *Test for albumin in the urine:* The urine must be perfectly clear. If not so, it is to be filtered, and if this does not render it transparent it is to be treated with a few drops of magnesia mixture and again filtered. The reaction is first observed. If it be acid, the urine is simply heated to near the boiling point. If the urine be neutral or alkaline, it is rendered *faintly* acid by the addition of dilute acetic acid and heated. If albumin be present a coagulum is formed, varying in quantity from a faint cloudiness to entire soldification, according to the quantity of albumin present. The coagulum is not redissolved upon the addition of HNO_3.

For sugar: Render the urine strongly alkaline by addition of Na_2CO_3. Divide about 6 c.c. of the alkaline liquid in two test-tubes. To one test-tube add a very minute quantity of powdered subnitrate of bismuth; to the other as much powdered litharge. Boil the contents of both tubes. The presence of glucose is indicated by a dark or black color of the bismuth powder, the litharge retaining its natural color.

For pus in the urine: Acidify the urine with acetic acid, then filter it, and treat the filter with a few drops of freshly prepared tincture of guaiacum; a deep blue color denotes the presence of pus.

To examine for indicanuria: "The urine is mixed with one-fifth of its volume of 20 per cent. solution of lead acetate and filtered. The filtrate is mixed with an equal volume of fuming hydrochloric acid containing 3:1000 of ferric chloride, a few drops of chloroform are added, and the mixture strongly shaken one to two minutes. With normal urine the chloroform remains colorless or almost so; but if an excess of indoxyl compounds be present the chloroform is colored blue, and the depth of the color is a rough indication of the degree of the excess."—(Witthaus' *Essentials of Chemistry and Toxicology.*)

Test for chyle in the urine: "As the chyle contains

serum albumin it would respond to the tests for that substance. To make out the fatty character of the molecular basis, a portion of the urine should be agitated with ether and potassium hydroxide, which dissolves the envelopes, and melts the fat particles together as a surface layer, leaving the urine clear beneath. The microscopic character is much like that of milk—that is, it contains myriads of small bright round particles which dissolve in ether."—(Holland's *Medical Chemistry.*)

8. "Milk is adulterated by the addition of water, by dilution, by subtraction of cream or skimming, by both watering and skimming, by the addition of thickeners, coloring, etc., and by the addition of artificial preservatives; it is also regarded as adulterated when it is below a certain chemical or bacteriological standard which is prescribed by a state or municipality."—(Price's *Epitome of Hygiene.*)

To test, a lactometer and creamometer are necessary, and various chemical tests should be made for the presence of formaldehyde, boric acid, borax, salicylic acid, and sodium carbonate or bicarbonate. These tests are too lengthy to be described here; and can be found in standard works on Food Analysis.

PATHOLOGY

1. "The terminal branches of the coronary vessels are end-arteries; that is, the communication between neighboring branches is through capillaries only. The blocking of one of these vessels by a thrombus or an embolus leads usually to a condition which is known as —(*a*) *anemic necrosis*, or white infarct. When this does not occur the reason may be sought in (1) the existence of abnormal anastomoses, which by their presence take the coronary system out of the group of end-arteries; or (2) the vicarious flow through the vessels of Thebesius and the coronary veins. The condition is most commonly seen in the left ventricle and in the septum, in the territory of distribution of the anterior coronary artery. (*b*) The second important effect of coronary-artery disease upon the myocardium is seen in the production of fibrous myocarditis. This may result from the gradual transformation of areas of anemic necrosis. More commonly it is caused by the narrowing of a coronary branch in a process of obliterative endarteritis. Where the process is gradual evidences of granulation tissues are often wanting, and any distinction between the necrotic muscle fibers and the new scar tissue is difficult to establish. The sclerosis is most frequently seen at the apex of the left ventricle in the septum, but it may occur in any portion. In the septum and walls there are often streaks and patches which are only seen in carefully made serial section. Hypertrophy of the heart is commonly associated with this degeneration. It is the invariable precursor of aneurism of the heart."—(Osler's *Practice of Medicine.*)

2. *Appendicitis:* "In the mildest or catarrhal form there is merely retention of the contents of the appendix and slight disease (swelling and erosion) of the mucosa. The muscularis and serous coat may be congested and edematous, but are not extensively involved. The contents of the appendix are more or less mucopurulent in character. In the necrotic or gangrenous form the mucous membrane suffers rapid destruction and the muscular and serous coats are quickly invaded. Fibrinous peritonitis soon develops in the serous coat and over the adjacent intestines, either as a result of penetration of bacteria through the walls of the appendix, or in consequence of perforation of the walls. The local peritonitis serves the purpose of restraining the infective disease and prevents diffuse peritonitis. In cases of rapid gangrene, with early rupture or escape of abundant bacteria, general peritonitis may result before a restraining wall can be formed."—(Stengel's *Pathology.*)

3. By *infection* is meant the invasion of the living tissues by living microorganisms which grow and multiply at the expense of the host. If only one kind of microorganism invades the host, it is a *primary infection;* if two or more kinds of bacteria are associated in this invasion, the result is a *concurrent* or *mixed infection;* a *terminal infection* is one occurring after a long period of weakness of the host, when a microorganism which would be powerless under ordinary conditions causes an infective process which is often fatal.

4. *Pathology of acute anterior poliomyelitis:* "The primary changes are in the vessels of the anterior horn (anterior spinal artery), which are congested, distended, and surrounded by small-celled infiltration. Thrombosis is common, but not necessarily present. Secondary interstitial changes take place in the gray matter, and its multipolar cells undergo cloudy swelling and ultimate destruction. Degenerative changes can be traced into the anterior roots. Later, the motor nerve trunks show marked change, the fibers being smaller and fewer in number. The neuroglia becomes increased, and the anterior horn as a whole is sclerosed and shrunken. The muscles are pale and flabby; atrophy begins early and is well marked; and microscopically, they show the changes already referred to, as the result of destruction of their trophic center. In the epidemic form there may be vascular irritation and cellular infiltration in the higher centers, but the ganglion cells of the medulla, pons, and optic thalamus usually escape; Flexner describes extensive hyperplasia of lymphoid tissues, and necrosis of small groups of liver cells."—(Wheeler and Jack's *Handbook of Medicine.*)

5. "The *causes of rapid death in the puerperium* may be any of the following: Accidents of labor, such as hemorrhage and shock following placenta prævia, accidental or post-partum hemorrhage, rupture or inversion of the uterus; rupture of a hematoma situated either externally on the vulva or within the pelvic cavity; rupture of peritoneal adhesions or of a broad ligament or an ovarian vein; acute purpura hæmorrhagica; cerebral embolism or apoplexy; hemoptysis; pre-existing diseases of the respiratory or circulatory system so grave as not to withstand the strain of labor, which is followed by extreme exhaustion and rapid death.

"Analysis of the recorded cases of *sudden death* include the following causes: Heart failure which has resulted from rupture of the heart due to fatty degeneration, to a patch of fibroid degeneration, to acute myocarditis. Sudden arrest of the heart's action has followed primary thrombosis in the right side of the heart, the thrombus extending into the pulmonary artery, or more frequently the cause of death has been embolism of the pulmonary artery. Rupture of a cyst in the auricular septum of the heart, of an aneurysm, of the aorta itself, and an attack of angina pectoris have caused immediate death. Mental emotion, such as profound impression of sorrow, of joy, of anger, of exaggerated shame, of excessive pain, or of fear, has caused sudden death by producing syncope, the heart's action being interrupted by energetic and persistent excitation of the inhibitory nerves of the heart. Sudden death has followed the entrance of air into the uterine sinuses; a fatal case has been recorded from embolus of fat from the pelvic connective tissue, and death in the puerperium has followed rupture of a gastric ulcer and of a liver-abscess. The most frequent causes of sudden death in the puerperium, arranged in the order of their relative frequency, are embolism, entrance of air into the uterine veins, and heart failure, due usually to organic disease."—(American *Text-Book of Obstetrics.*)

The post-mortem findings will depend on the pathological condition present.

6. "In *mitral stenosis* there is an increase in the intra-auricular pressure toward the end of auricular diastole, due to the blood from the lungs flowing into an insufficiently emptied auricle; the consequent dilatation and stretching excite the auricle to very vigorous contractions, which become augmented in consequence of the obstruction to the discharge of blood. The result is an extraordinary enlargement (hypertrophy and dilatation) of the left auricle, which may attain dimensions three or four times the normal. Increased intrapulmonary pressure is followed by hypertrophy and dilatation of the right ventricle, which as in mitral insufficiency is the efficient factor in maintaining compensation. In some cases, for a time at least, the increased power of the left auricle serves to supply a normal amount of blood to the left ventricle, which in consequence presents no noteworthy deviations from the normal. In many cases, however, on account of associated mitral insufficiency, the left ventricle is somewhat enlarged; in most cases the amount of blood supplied to the left ventricle is less than normal, in consequence of which it is often said to become reduced in size (this is more apparent than real)."—(Kelly's *Practice of Medicine.*)

"When compensation fails the various organs of the body suffer congestion. The lungs are first affected in disease of the left heart (mitral and aortic disease).

The capillaries of the pulmonary alveoli become over full and encroach upon the lumen of the alveoli, or by elongation stretch the alveolar walls and render them inelastic. In either case proper respiration is prevented —a condition which is further aided by the retarded pulmonary circulation. As a result of these conditions, dyspnea (cardiac asthma), cough, and expectoration develop. In extreme cases edematous exudation takes place, and in long-continued cases cyanotic induration of the lung occurs. In such instances there may be continuous cough and respiratory insufficiency. When the right heart fails, the liver, spleen, gastro-intestinal mucosa, the kidneys, and the peripheral circulation suffer congestion. The liver may become greatly engorged, and in certain cases actually pulsates with each ventricular systole. The swollen liver-cells and the engorged vessels cause obstruction of the biliary capillaries, and consequently produce jaundice. To some extent this may be due to associated congestion of the biliary channels. Congestion of the gastro-intestinal mucosa may occasion various forms of gastric or intestinal derangement."—(Stengel's *Pathology.*)

7. *"Pott's disease":* The lower dorsal region is the commonest situation, but any part may be affected. The disease begins—(1) Under the periosteum of the anterior surface of the bodies of the vertebræ. The disease spreads to the adjacent vertebræ. The bodies and intervertebral discs are destroyed, so that a gradual curvature is produced. (2) In the interior of the bones, near the intervetebral cartilages, and rarely affecting more than one or two vertebræ. As the bones become destroyed the weight of the body causes the vertebræ above to sink down, and so more or less acute curvature results. The disease may run its course with or without suppuration."—(*Aids to Surgery.*)

8. An *autogenous vaccine* is one that is prepared from material derived directly from the patient who is to be inoculated with it. *Vaccine therapy* is based on the supposition that bacterial vaccines when introduced into the patient's body cause a condition of active immunity against the corresponding pathogenic germs or their toxins; it is further believed that they raise the opsonic value of the blood and so promote phagocytosis of the invading bacteria.

(*To be concluded.*)

BULLETIN OF APPROACHING EXAMINATIONS

STATE	NAME AND ADDRESS OF SECRETARY	PLACE AND DATE OF NEXT EXAMINATION.†	
Alabama*	W. H. Sanders, Montgomery	Montgomery	Jan. 12
Arizona*	J. W. Thomas, Phoenix	Phoenix	Jan. 5
Arkansas	W. S. Stewart, Pine Bluff	Little Rock	
California	C. B. Pinkham, Sacramento	Los Angeles	Dec. 8
Colorado	David A. Strickler, Empire Building, Denver	Denver	Jan. 5
Connecticut*	Chas. A. Tuttle, New Haven	New Haven	Mch. 9
Delaware	J. H. Wilson, Dover	Dover	Dec. 15
Dist. of Col'bia	Geo. C. Ober, Washington	Washington	Jan. 12
Florida*	E. W. Warren, Palatka	Palatka	Dec. 2
Georgia	C. T. Nolan, Marietta	Atlanta	June 2
Idaho*	J. F. Schmershall, Jerome	Lewiston	April 6
Illinois	C. S. Drake, Springfield	Chicago	Jan.
Indiana	W. T. Gott, Crawfordsville	Indianapolis	Jan. 12
Iowa	G. H. Sumner, Des Moines	Des Moines	
Kansas	H. A. Dykes, Lebanon	Topeka	Feb. 9
Kentucky	J. N. McCormack, Bowling Green	Louisville	Dec. 16
Louisiana	E. L. Leckert, New Orleans	New Orleans	June 3
Maine	F. W. Searle, Portland	Portland	Mch. 9
Maryland	J. McP. Scott, Hagerstown	Baltimore	Dec. 8
Massachusetts*	W. P. Bowers, State House, Boston	Boston	Mch. 9
Michigan	B. D. Harison, 205 Whitney Building, Detroit	Ann Arbor	June 8
Minnesota	T. McDavitt, St. Paul	Minneapolis	Jan. 5
Mississippi	S. H. McLean, Jackson	Jackson	May 11
Missouri	J. A. B. Adcock, Jefferson City	St. Louis	Dec. 14
Montana*	Wm. C. Riddell, Helena	Helena	April 6
Nebraska	H. B. Cummins, Seward	Lincoln	
Nevada	S. L. Lee, Carson City	Carson City	May 3
N. Hampshire	Henry C. Morrison, State Library, Concord	Concord	Dec. 29
New Jersey	H. G. Norton, Trenton	Trenton	June 22
New Mexico	W. E. Kaser, East Las Vegas	Santa Fe	Jan. 11
New York	H. H. Horner, Univ. of State of New York, Albany	New York / Albany / Syracuse / Buffalo	Jan. 26

Wyoming	H. E. McCollum, Laramie		

*No reciprocity recognized by these States.

†Applicants should in every case write to the secretary for all the details regarding the examination in any particular State.

Items.

Cubitus Varus Following Fracture of the Lower End of the Humerus.—P. Turner reports a case of a female, aged 13 years, who was admitted to the hospital in January, 1913, for deformity of the left elbow. Six and a half years before she had a fracture of the lower end of the humerus as the result of a fall. The fracture appears to have been treated with an internal angular splint. The deformity followed the fracture, and for the past two years the elbow has been so painful that it could scarcely be used. On admission full flexion was possible, but on straightening the arm it became markedly adducted at the elbow owing to the alteration of the carrying angle, and could be over-extended. Pronation and supination were normal. All movements caused much pain. At the operation the humerus was divided transversely immediately above the condyles, and the arm put up in a position of full flexion. Massage and passive movements were started at the end of two weeks. The axis of the forearm now bears practically the normal relation to that of the arm and the joint can be freely moved without causing pain. Full extension is however impossible. Functionally the arm has been greatly improved by the operation.—*Proceedings of the Royal Society of Medicine.*

Pathogenesis of Congenital Hemolytic Icterus.—A. Chauffard reports an interesting group of cases of this condition occuring in one family. This group comprised a father who was jaundiced from birth and twin daughters aged 17 years, both of whom were also icteric from birth. There was another daughter aged 8 years who was not jaundiced. In studying this group of cases the author has come to the conclusion that congenital hemolytic icterus has a pathogenesis of a dual nature. There is an hereditary factor either syphilitic or tuberculous and a factor consisting in the hemolyzing reaction of the spleen. Unfortunately up to the present time no cure has been obtained. The administration of neosalvarsan to the twins had a doubtful effect. Radiotherapy applied to the spleen has been reported by Pareso and Heully in 2 cases with appreciable results. Splenectomy has been reported as an important measure but the operative mortality is quite high.—*Annales de Médeeine.*

Case of Osteitis Deformans; Operation for Fractured Femur.—G. Taylor reports the case of a patient aged 56, who was admitted to the Middlesex Hospital on April 29, 1913, for a fracture of the middle of the shaft of the right femur. Attempts to secure proper apposition of the fragments by means of splints and extension were not successful, and on May 16 an operation was performed, and the fragments were fixed by means of a Lane's plate. Recovery was uneventful, and he was transferred from the wards to the out-patient department under the author's care on July 16. Before leaving the wards he was discovered to be suffering from osteitis deformans. Both femur and tibia were bowed; the upper part of the spine was fixed in its bowed position; the clavicles were enlarged and the bones of the upper extremity were also slightly curved. There appeared to have been no change in the dimensions of the cranium. The condition did not appear to have influenced the union of the fracture in any way. —*Proceedings of the Royal Society of Medicine.*

Abscesses of the Larynx in Childhood.—Descattes reports thirty cases of this condition which he regards as relatively rare. Laryngeal suppuration may occur following measles, grip, diphtheria, variola, scarlatina, and typhoid fever, but chiefly following diphtheria, measles, and grip. In retropharyngeal abscess the pus may be evacuated at the level of the larynx. In measles abscess formation about the larynx may be primary or may be secondary to a laryngitis, either diphtheritic or non-diphtheritic. In diphtheria perilaryngeal suppuration occurs, most frequently following intubation as the result of ulceration of the larynx. The symptoms of abscess of the larynx are obscure. There may be a tumefaction of the tissues of the neck or an edema of the glottis. As soon as the diagnosis is made or suspected, prompt incision from the outside is imperative.—*Rassegna di Pediatria del Prof. Cattaneo.*

PRECANCEROUS DISEASES AND PRECANCEROUS LESIONS, ESPECIALLY IN THE BREAST.*

BY J. EWING, M.D.,

NEW YORK.

WHENCE and how does cancer develop? The two queries cover the subjects of the formal and the causal genesis of the disease. The formal genesis of cancer is a morphological study which traces the fully developed tumor to the cells of origin. The causal genesis is a physiological subject and deals with the factors which bring about the tissue changes observed.

Until the sources and developmental stages of cancer are rather fully traced the study of causal genesis must proceed under difficulties. Hence for many years minute attention has been given to the very earliest stages of carcinoma and no diagnosis of tumors can be regarded as satisfactory unless the exact cells of origin can be stated.

The formal genesis of a large class of neoplasms was disposed of by Cohnheim, and by many others before and after him, who traced the beginnings of tumors in congenitally misplaced and often embryonal cell groups. While it is still impossible to state how far the principle of Cohnheim's theory applies to tumor genesis, the comprehensive list of observed tissue abnormalities predisposing to tumor growth as catalogued by R. Meyer, R. Williams, and contributed by many others, far exceeds anything Cohnheim could have postulated. The theory may also be made to include structural abnormalities or tissue predispositions which are not revealed by obvious microscopical changes, but which there is strong reason to believe exist.

On the other hand, clinical observation has long asserted that the great majority of important tumors are not determined by congenital abnormalities in tissue structure, but arise from once normal but previously altered tissue cells, and that various forms of chronic inflammation are observed to precede the development of most tumors.

Thus Billroth observed that cancer almost never arises in a normal breast. v. Brunn, among 368 cases of cutaneous cancer of the limbs, found only 48 in which no previous alteration in the tissues could be demonstrated. v. Bergmann stated that primary cancer of the extremities without previous changes in the skin does not exist. In the various organs throughout the body it is universally recognized that certain pathological conditions are followed in a variable but high proportion of cases by carcinoma. For these conditions Orth employs the term "precancerous diseases," but it should be emphasized that these diseases possess in themselves not a single essential element of the cancerous process. They are merely observed to precede and favor the development of cancer.

A glance at some of these diseases serves to show how intimate is the connection between the so-called precancerous disease and the tumor process, and under what conditions the one follows the other.

Cutaneous Cancer.—In the skin Darier recognizes three distinct precancerous conditions: (1) Malformations, (2) non-inflammatory degenerations, and (3) inflammatory processes and their sequels.

(1) The chief malformation leading to cancer is the nævus, which becomes malignant in a small proportion of cases and under conditions which have not been clearly defined. Darier has treated them with many destructive agents and never saw cancer develop from the irritation. Yet the case of the nævus is distinctly different from that of the true precancerous lesion and might better be considered in a separate category. Melanoma springs fullfledged from the focus of origin without the long preliminary changes observed in strictly precancerous lesions.

(2) Senile and presenile degeneration of the skin takes the general form of keratosis, and is seen in the seaman's skin, and other disorders leading to multiple cancer. It affects exposed regions subjected to repeated irritation of sunlight, heat, and cold. There is often an hereditary element. There is first hyaline degeneration of the derma, sclerosis of vessels, and atrophy of the Malpighian layer with thickening of the horny layer. Then follow keratosis, scaling, papillary outgrowths, and elongations of deep papillæ. Then very gradually the invasive and destructive features of carcinoma are added. Yet the process in the senile skin is not always the same and Janeway has described as the initial precancerous lesion foci of very large hyperchromatic cells without notable hyperplasia or heterotopia.

In xeroderma pigmentosum there is a family cutaneous dystrophy occurring in infants, marked by dry atrophic, or pigmented, or telangiectatic patches in the skin. After eight to ten years epithelioma resembling the senile type often develops. Arsenical cancer takes much the same course.

(3) Cutaneous cancer of inflammatory origin. In the skin well-known forms of cancer follow in the cicatrical tissue from burns, tuberculous and syphilitic lesions, and amputation wounds. It is characteristic that a long period usually elapses before cancer develops in scars, and that the tumor is very apt to be multicentric or diffuse in origin. The most extensive cancer v. Bergmann ever saw, covering much of the trunk, was in a man of forty years who at four years of age suffered an extensive burn. Many cases, however, develop within

*Read at a meeting of the Practitioners' Society, October 9, 1914.

five to ten years. The entire area involved in the lesion is usually included in the resulting cancer. Letulle mentions a case of appendical carcinoma arising in an old sclerosed and atrophic organ, and the majority of these cases are preceded by chronic productive inflammation with fibrosis, according to Zaiger 50 per cent., according to Milner 85 per cent. Lupus carcinoma arises in the active lesions of the tuberculous process, but in 30 per cent. of the cases in the scar tissue (Steinhauser). The fact that it comes about the thirtieth year of the disease and never before the fifth shows that considerable cicatrization is an essential preliminary. Several cases of carcinoma in syphilitic scars are reported by Ashihara.

X-ray dermatitis shows a remarkable tendency to develop carcinoma through a process in which cicatrization is an essential factor. A period of three to eleven years is required for the appearance of the malignant process, which is preceded by necrosis of the tissue, occlusion of blood and lymph vessels, fibrosis, and overgrowth of epithelium (Porter, Wolbach). In the more chronic cases fibrosis and atrophy predominate and the lesion resembles premature senescence (Lindhorn).

The scarring of ulcers is a well-known condition predisposing to cancer. A familiar example is the eczematous and varicose ulcer of the leg which if given time occasionally results in epithelioma.

The relation of gastric ulcer to cancer still remains to be defined. Among recent writers Hirschfeld places the proportion of ulcers that become cancerous at 5 to 6 per cent., and summarizes clinical and statistical data indicating that the proportion is small. Boekelmann collects a series of estimates varying from 3 to 5 per cent. In Vienna 2 per cent. of the subjects coming to autopsy show scars of healed ulcers. In France opinions are widely at variance. Wilson and McCarty from the Mayo clinic report that 68 per cent. of their gastric ulcers were complicated by carcinoma. In my own material, both surgical and post mortem, the proportion is much less, and I sometimes find it difficult to distinguish between ulcerating cancer and cancerous ulcers. In no field is the minute analysis of the histological changes preceding cancer more difficult or important. As a rule cancer develops only in ulcers of long standing and after a preliminary period of multiple adenomatous growths on the margins of the ulcer.

Cancer Resulting from Chronic Productive Inflammation of Glands or Mucous Membranes.—The most notable example of carcinoma following chronic inflammation is probably that observed in the gall-bladder from cholelithiasis. The disease forms 5 or 6 per cent. of all carcinomas (Kaufmann), and is four or five times as frequent in women as in men. Gallstones were present in 69 per cent. of Musser's 100 cases; 70 per cent. in Futterer's; 85 per cent. in Zenker's, 91 per cent. in Courvoisier's, 95 per cent. in Siegert's, and 100 per cent. in Janowski's. The proportion of cases of cholelithiasis which develop cancer is placed by Rolleston at 4 per cent., by Slade at 18 per cent. Slade found microscopical cancer in ten of seventeen cases, 59 per cent. Yet Candler found only two gross cancers in 315 cases of gallstones among the insane. Since cancer rarely produces gallstones, the calculi cannot be regarded as the result of the tumor. The tumor arises early in the course of lithiasis and takes a papillary or glandular character, or late, and then takes the form of infiltrating or fibrocarcinoma.

Aschoff and Pels-Leusden believe that irritation by cholesterin granules in the tubules of Luschka's gland (branching off from the vesical mucosa) is a frequent source of gall-bladder cancer. Menetrier points out that the proliferating glands especially in the polypoid outgrowths apparently at the stage of simple adenoma are capable of invading muscularis and lymphatics.

A well-defined form of hepatic carcinoma arises from chronic irritation and stasis of the larger bile ducts.

There appears to be something in the chemical or mechanical nature of the irritation by cholesterin which is peculiarly effective in producing atypical proliferation of epithelium.

In the uterus chronic catarrhal endocervicitis precedes cancer in the great majority of cases (34 of 48, Polese). The cervical erosion is the most definite established lesion known to precede cervical carcinoma. Next comes leucoplakia of portio and canal which is often combined with erosion. Beckmann carefully watched the development of carcinoma in an erosion which he treated for five years. Early stages of the development of carcinoma from such lesions are described by Waldeyer, Ruge and Veit, Cullen, Scharenstein, Sitzenfrey, and others. I have studied three quite perfect examples of precancerous polyps of eroded cervices showing metaplastic overgrowth and just beginning invasion of the stroma by adenocarcinoma. In one case a squamous cell carcinoma is beginning lower down in the cervix.

For corpus carcinoma the chief definite etiological factor is the association with myoma, 10 per cent. of which, according to Olshausen, give rise to carcinoma in the overlying and chronically irritated mucosa. Local hyperemia and chronic endometritis are constant accompaniments of myoma, and ulceration is frequent. I find that many stages of inflammatory overgrowth up to adenoma and adenocarcinoma may be followed by routine study of these cases. Leucoplakia of the endometrium is chiefly associated with the corpus carcinoma of elderly subjects which takes the form of acanthoma or adenoacanthoma (Benckizer). Yet many cases of leucoplakia uteri run a prolonged benign course (Zeller).

Although Gebhard claimed that malignant adenoma commonly arises from the hypertrophied glands of chronic endometritis this simple explanation has not been fully verified. Heurlin in 44 cases failed to find any transitional stage or any glandular endometritis in the outlying mucosa. Yet 29 of his 44 cancers were diffuse. It seems probable that when corpus carcinoma develops on glandular hyperplasia it first passes through an adenomatous stage. In routine material I find such transition stages rather frequent, but clinical observations in this field are still inadequate to prove the close dependence of corpus adenocarcinoma on inflammatory processes. I have only once observed a very marked grade of glandular overgrowth recur as adenocarcinoma in curettings received after an interval of two years.

In the urinary bladder the great majority of cancers can be traced to previous or coexistent cystitis. The multiplicity of vesical papillomas indicates the existence of widespread lesions in the mucosa from which tumors may develop. Stoerk has traced a definite relation between cystitis cystica and multiple papilloma, and he and Cahen report cases of the former developing into carcinoma.

Specific vesical irritants as observed in anilin workers are especially effective in producing vesical carcinoma, chiefly at the ureteral orifices (Rehn, Leichtenstern). A high proportion (50 per cent.) of these tumors are malignant (Seyberth).

In Bilharzia disease there is a series of changes, including venous and lymph stasis, catarrhal cystitis, irritation from ova, and lithiasis, which have been shown by Goebel and others to lead in many instances to carcinoma.

In epithelioma of the penis, which forms from 1 to 3 per cent. of all carcinomas in males, phimosis and syphilis are very common antecedents. Demarquay found phimosis in 85 per cent. of his cases and Kaufmann saw balanitis with warty vegetations in 29 of 33 cases. Hebrews are practically immune. Thompson describes as a precancerous condition a catarrhal balanitis with desquamation followed by hypertrophy of epithelium and subepithelial connective tissue. Schuchardt calls this condition psoriasis preputialis.

Buccal and lingual cancer stands second according to Jessett in order of frequency, third according to Jacobson, and fourth in Winiwarter's statistics and shows a mortality of 75 per cent. to 90 per cent. (Warren, Meller). This disease is preeminently due to inflammation and local irritation. The combination of syphilis, tobacco, and bad teeth is present in a large group of cases and one of these factors almost always exists. While Meller found signs of lues in only 7 of 207 cases, Fournier regarded 155 of 184 cases as luetic. The syphilitic process usually takes the form of leucoplakia, of which 30 per cent., according to Fournier (15 per cent. Darier), develop carcinoma. In these cases there is hypertrophy and hyperplasia of epithelium, hyperkeratosis, lymphocytic infiltration of submucosa, papillomatous overgrowth, and finally destructive invasion of the deep tissues. All these processes require time. According to Darier the complication of an ulcer or fissure is usually necessary before leucoplakia becomes cancer. Other syphilitic lesions observed to precede cancer are wart-like hypertrophies, fissures, gummas, and chronic atrophic glossitis (Jacobson). The syphilitic process may completely heal while cancer develops later in the scar under a smooth epidermis. As long ago as 1872 these various buccal lesions were designated by Hutchinson as precancerous.

Physiological involution of organs and the complicating mechanical, nutritional, and inflammatory processes, precede the development of cancer chiefly in the breast and prostate. Definite neoplastic tendencies in the "maladie de Reclus" were first pointed out by Brissaud and by Schimmelbusch and confirmed by many later writers. It is especially in that form of chronic mastitis in which cysts and epithelial proliferation are prominent from the first that cancer is observed to develop, but no anatomical form of the disease is free from the dangers of malignant change. Bloodgood prefers to regard most of the cases as pure senile involution. Regarding the relation to cancer, opinions are as usual at variance. It is quite true that certain cases pursue a benign course for many years. Hence Delbet and many surgeons consider the disease as essentially benign although incurable. Against this conclusion stands a large body of clinical evidence which has been steadily increasing in recent years. Billroth stated that small cysts are very often seen about mammary cancers. Tietze described five such cases in detail and Verga reports a similar series. Tietze concluded that 10 per cent. of cases of chronic cystic mastitis develop cancer and Speese in 295 cases found 15 per cent. showing carcinomatous areas. Greenough and Hartwell found three cases of cancer in 30 of chronic mastitis, and Warren reported 15 in 150 cases (13 per cent). When one includes various suspicious areas histologically resembling cancer but not admitting of positive interpretation the proportion of precancerous conditions in chronic mastitis becomes much higher. In my material for the analysis of which I am indebted to Dr. B. J. Lee, it reaches at least 25 per cent. In cases of mammary carcinoma interstitial mastitis is practically constant but may be secondary.

Brodie, Brissaud, Reclus, Sourice, Schimmelbusch, Saar, and many others have declared that the step from chronic mastitis to carcinoma is short and often traversed.

In the prostate the chief condition predisposing to cancer is chronic prostatitis, usually with hypertrophy. The principal age of incidence of both conditions is the seventh decade when 68 per cent. of the carcinomas occur. Notable examples of the transformation of simple hypertrophy into carcinoma are recorded by many observers (Wolff, Kaufmann, Albarran, Halle, Greene and Brooks, Young). The evidence usually consists of a long history of hypertrophy in cases presenting carcinoma. At least 10 per cent. of prostatic cancers give such history. Among 500 cases of prostatic obstruction Young found 20 per cent. cancerous, and he states that about 15 per cent. of enlarged prostates after 50 years are cancerous. The proportion is placed by Albarran at 14 per cent.; by Walker at 16.5 per cent.; Wilson and McGrath, 15.5 per cent.; Freyer, 13.3 per cent. In most of these cases the process was interrupted by operation and its capacity to develop cancer was not revealed. Wolff saw carcinoma develop after incomplete extirpation of an enlarged prostate. Whatever the nature of prostatic hypertrophy may be it is clear that the influence of physiological involution is usually concerned.

Regenerative hypertrophy may be regarded as the predominant underlying influence in the development of certain forms of cancer, of which the best examples are seen in the thyroid gland and liver. In fish the functional overactivity and hypertrophy of the thyroid observed in crowded ponds where the animals are fed on protein diet leads in a small proportion of cases to maligant overgrowth, which is a specific form of cancer. This condition has been reproduced under experimental conditions and fully traced by Gaylord. There is reason to believe that the thyroid cancer of young girls and possibly at later ages sometimes arises under parallel conditions. Few cases of thyroid carcinoma develop in subjects with entirely normal thyroid history, but many follow goiter, interstitial thyroiditis and Graves' disease.

In the liver an important group of primary carcinomas or hepatomas represents malignant overgrowth of regenerating lobules following injury with degeneration or cirrhosis (Hanot, Gilbert, Menetrier.) Probably many tumors of the kidney, adrenal and hypophysis are of the same nature.

The transformation of benign into malignant tumors is a very frequent source of cancer, universally recognized, occurring in nearly all organs, and of prime significance in considering the origin of cancer. Many of these benign tumors are clearly

of inflammatory origin, and the organs may present every gradation between simple inflammatory overgrowth, adenoma, and carcinoma. The most striking example occurs in the gastrointestinal tract and especially in colitis polyposa. This disease affects both old and young subjects and exhibits an hereditary, individual, and local predisposition. In the early stages the epithelium presents a peculiar and excessive reaction to some irritant, and catarrhal symptoms are marked. Then follow localized polypoid outgrowths, multiple adenomas, and carcinoma. According to Quenu and Landel about half the cases develop carcinoma. Hauser found this combination the rule, and of 50 cases analyzed by Doering 31 of 37 fatalities were from carcinoma.

The transformation of single benign gastric and intestinal polyps into carcinoma has been described in detail in a series of communications by Menetrier. According to this observer gastric ulcer leads to cancer through the preliminary development of polypoid adenomas on the edge of ulcer.

The foregoing brief series shows how very numerous are the pathological processes, which in a high proportion of cases are known to be followed by cancer. The list might be still further extended. These clinical observations form the chief basis for the classification of many cancers in the so-called "irritation group." The data cited are almost entirely clinical. The events in sequence ending in cancer are merely observed to follow one another, but this sequence does not prove that there is any essential relation between the processes. It is, therefore, questionable if the term precancerous disease is legitimately chosen. In fact, many have claimed that when mammary cancer follows chronic mastitis, one disease has been grafted upon an entirely different disease. It has been affirmed that a pathological condition is either cancer or not cancer.

To combat this highly mechanical notion of biological processes it is necessary to show that there is an essential connection between the preliminary disease and the resulting cancer and this can be done only by close microscopical study of precancerous conditions. This study has fully demonstrated that an extensive series of structural changes takes place in the precancerous diseases leading up to the fully developed cancer, the one passing by insensible gradations into the other. It is not true that a pathological condition must be either cancer or not cancer. It may be neither the one nor the other. It may be in the process of becoming cancer. This process takes time, sometimes years, and may be accompanied by very striking histological changes which may be difficult to classify, since they lie between inflammatory and neoplastic hyperplasia. To this series of intermediate stages of hyperplasia revealed by the microscope in diseases clinically observed to pass into carcinoma the term "precancerous lesion" may be applied.

I believe, however, that only when the preliminary lesion shows a definite advance into the field of genuine cancerous change can the term precancerous be properly applied. Otherwise almost every form of chronic productive inflammation may be regarded as precancerous since in some instances the particular condition clinically passes into carcinoma. Yet not every case of chronic mastitis shows suspicious changes suggesting carcinoma. When any case does exhibit the suspicious structures then and only then can it be regarded as precancerous.

I believe, further, that a distinction should be made between precancerous lesions and miniature carcinomas. All the local signs of malignancy may be exhibited in comparatively minute foci of cells, and may be observed in chronic mastitis, and while the circumscribed lesion may not reveal its potentialities to the clinical observer the microscope detects the malignant capacities with complete certainty. Only in size do such miniature carcinomas differ from the established disease. Such lesions cannot properly be called precancerous since they exhibit the essential features of fully developed carcinoma, only on a small scale.

The data which support the principles here stated are derived from the microscopical study of cancer and precancerous lesions and their elucidation requires an analysis of the essential features of the carcinomatous process. Some features of this analysis may here be considered.

Histological Criteria of Carcinoma.—It must be noted that the histological criteria of carcinoma differ greatly in different organs and that only by clinical observation have we been able to determine and predict the momentum and the probable course of different malignant tumors. The significance of the various changes belonging to the cancer process must be learned for each organ. Moreover, cancer of the same organ exhibits in widely different degrees the histological features of carcinoma. Thus some malignant cancers of the thyroid differ so little from the structure of the normal gland that Cohnheim called them benign metastasizing struma, and Riedel, Oderfeld, and Steinhaus erroneously concluded that the normal alveoli of the gland might pass into the blood stream and produce distant tumors. Here the metastasizing property was developed far in excess of other carcinomatous features. On the other hand, extreme grades of somewhat atypical cellular hyperplasia with giant cells and ill-formed alveoli are observed in the wholly benign goiter of Graves' disease.

In the stomach a comparatively orderly adenomatous hyperplasia is usually malignant and may be found in distant metastases, while in the rectum a similar degree of glandular overgrowth constitutes a harmless polyp. It is extremely difficult to establish any universal criteria of the cancer process and I find that some who have attempted to do so encounter many difficulties. Thus Borst applying a somewhat rigid conception of carcinoma hesitates to accept many very malignant hepatomas as true cancers because they fail to show the local aggressive properties of many carcinomas and are mechanically forced to grow into the hepatic vessels. These few illustrations among many that might be cited, suffice to show that there are many morphological details in cancer processes, and that all are not equally developed in every genuine cancer.

Probably the best definition of the cancer process is "atypical and destructive proliferation of epithelium." Yet many well known forms of cancer fail to meet these requirements and it becomes necessary to analyze the process in much greater detail in order to admit many malignant diseases into the cancer category. This analysis requires the recognition of at least the following criteria of a malignant process: (1) Cellular overgrowth passing beyond that observed in other processes affecting the same tissue; (2) atypical qualities of the cells, metaplasia, anaplasia; (3) loss of polarity; (4) heterotopia; (5) desmoplastic properties; (6) local invasive and destructive properties; (7)

metastases. It will be observed that in each of these characters variations in degree are conceivable and, as a matter of fact, they are commonly observed to occur.

Any one of the above attributes of cancer may be almost exclusively represented in the disease. Excessive cellular overgrowth difficult to distinguish from a physiological type chiefly characterizes some thyroid cancers. Atypical qualities of the cells are the only safe criteria of early malignant papilloma of the larynx. Loss of polarity is the chief feature of certain large alveolar mammary carcinomas confined within ducts. A pronounced fibrosis about slightly altered prostatic alveoli was the most definite feature of a fatal case of prostatic cancer which I have recently studied. Local invasive and destructive properties first reveal the beginnings of some lymphosarcomas. Distant metastases are the chief evidence of malignancy in the peculiar thyroid cancers previously mentioned. Hence the diagnosis of cancer becomes a matter of judgment as to the significance of any one or all of the above features that may be combined in any one cancer. The disease is not always one and the same thing. On the contrary, it is a progressive process which has small and variable beginnings and unfolds more and more of its features as it advances to a fatal issue. It is from this point of view that the significance of precancerous lesions must be regarded. From this standpoint such lesions may be defined as pathological processes which show some, but not all, of the structural features which characterize fully established cancers of the affected organ.

To what extent, then, are the criteria of cancer presented in the various conditions designated as precancerous diseases? Time fails for a full discussion of the many precancerous lesions in the several organs, but a few illustrative cases may be considered, of which the breast is perhaps the most fertile field.

The gradual passage by many transitional stages of the nutritional and inflammatory changes of chronic mastitis into cancer has been traced by many observers and in such detail as to leave no reasonable doubt that these authors have been describing stages of one and the same process. It may be fully admitted that these stages in order to form an unbroken chain must usually be taken from a series of cases, no one breast furnishing them all. Constructed in this way the fabric of proof is without a break.

Prominent among the early changes is the development of small cysts of lacteal, interlobular, or intralobular ducts filled with puriform, fatty, or blood-stained material. Into these cysts project low papillæ of proliferating epithelium which gradually enlarge, exhibiting a grade of overgrowth which passes the inflammatory limit. No other neoplastic feature may be present and we speak of the lesion as papillary adenoma. Since the papillary outgrowths may recede after evacuation of the cyst many of these lesions in the breast and other organs must be regarded as inflammatory and not adenomatous. Yet in others the growth becomes progressive. Other cysts show marked increase in the size of the cells and nuclear hyperchromatism. Loss of polarity appears in disordered multiple layers of cells but there is yet no heterotopia, which is added when stroma or capsules are invaded by atypical cells completely displaced from their normal attachments. Or, loss of polarity may be prominent from the first when the cyst is lined by multiple layers of atypical cells. Thus may be traced the development of the series of cyst adenomas and carcinomas, many of which develop in chronic mastitis. In other cases cysts are not prominent, but an interstitial productive process affects the lobule. The acini show from the first a notable tendency toward overnutrition and overgrowth, interpreted by Brissaud as a neoplastic process. The acini assume the characters of ducts as in the fetal breast. The cells multiply producing lateral sacculi and many new regular alveoli as exclusively seen in one form of adenoma; or more often the cells multiply rapidly, become atypical, exhibit loss of polarity, heterotopia, and soon local invasive properties. By these stages many of the circumscribed hard fibrocarcinomas develop in chronic interstitial mastitis.

Periductal fibrosis affecting one or more isolated portions of the breast may lead to extensive proliferation of lining cells which in various phases exhibit simple overgrowth, later atypical cell characters, loss of polarity, diffuse growth within a limited segment, then heterotopia and invasive properties.

Both ducts and acini participate in the abnormal proliferative changes, but in most cases the acini assume the characters of ducts and the distinctions between the two structures are obliterated. The aberrant sweat glands described by Moullin, Dryfuss, and Krompecher are often involved, producing cysts lined by strongly acidophile cells. The tumors derived from these cysts contain large granular pavement-like cells. In other cases the proliferation of acini is the predominant feature.

In the single case of chronic mastitis the suspicious areas are usually multiple and often numerous. They are best detected by examination of the breast in the fresh condition when they appear as unusually hard shotty nodules, or as small cysts with softened walls, or as cysts with opaque cellular contents. Of ten such nodules chosen from one breast in a case of Gibson's I found three groups of distended ducts diffusely filled with atypical cells and one miliary cystadenoma. The whole breast may be uniformly affected or the proliferation may be most advanced and atypical in one segment. As a rule the suspicious areas are more abundant in the more advanced cases. In some very small and very atrophic breasts I have found distinct precancerous lesions or miniature carcinomas. These cases correspond to those in which a very small breast is everywhere transformed into carcinoma. Thus several different gross forms of carcinoma seem traceable to the types of precancerous changes observed in chronic mastitis.

The proportion of cases of chronic mastitis which may be classed as showing precancerous lesions depends largely on the standards employed in interpreting abnormal proliferation. It should be emphasized that considerable proliferation and desquamation of epithelium is seen in nearly all cases of chronic mastitis and senile involution and unless quite specific changes are demanded before employing the term precancerous, one must consider all cases of chronic mastitis as dangerous. Widely distended ducts diffusely filled with atypical cells, pronounced multiplication of alveoli with obliteration of acinar outlines, and miliary adenomas with areas of diffusely growing large atypical cells, would seem to require recognition as tending distinctly toward malignant growth. Some of these lesions closely

approach miniature carcinomas, but are restrained by the thickened walls of ducts or other fibrous barriers. The comparative frequency of such lesions in the breast at many ages suggests that when carcinoma is observed to follow trauma it is through the liberation of cells growing under confinement in the cysts and proliferating ducts of chronic mastitis. Likewise when carcinoma develops after imperfect extirpation of fibroadenoma the trauma may liberate and accelerate the growth of the suspicious areas often seen in or about benign tumors.

Notwithstanding the close resemblance of precancerous lesions in the breast to carcinoma the actual passage of the one into the other is not to be accepted without searching criticism.

It may be that the suspicious lesions never pass beyond the stage at which they are observed. Only a minority of cases of chronic mastitis develop carcinoma, while atypical epithelial proliferation is rather common. Moreover, not a few cases of chronic mastitis progress for years without malignant transformation. It is necessary to admit that the mere discovery of precancerous lesions does not assure in every instance that the process was bound to become carcinoma.

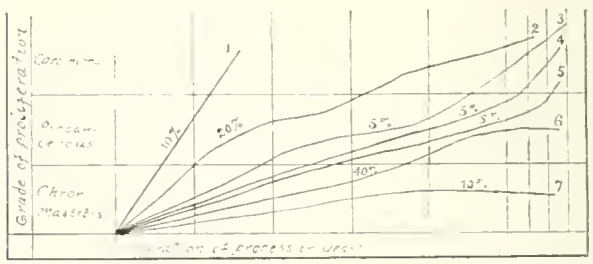
Nevertheless that some of the lesions do progress to carcinoma is a conclusion that cannot well be doubted. The series of transitional lesions in a series of cases or even in the same case is complete. The law of the momentum of pathological processes justifies the deduction that when atypical overgrowth begins and the conditions inciting it persist, the proliferation tends to become more and more atypical and active. In accordance with this law is the observed fact that a high proportion of cases of recognized mastitis develop carcinoma. Even more convincing is the still higher proportion of cases of carcinoma found to occur in breasts which are the seat of unrecognized chronic productive changes.

The most serious argument against the theory of precancerous lesions is the fact that many carcinomas are not proven to be preceded by such changes. Some of the very earliest cancers observed in the breast have been too far advanced to permit tracing them to their cells of origin. Ribbert states that no one has ever seen the beginnings of mammary cancer. Moreover, when cancer does develop in chronic mastitis it very soon overgrows and obliterates the original lesions. There is often a perceptible gap between the atypical proliferation and the smallest established carcinomas. Hence comes the impression that when carcinoma is grafted on mastitis a wholly new disease is added. I have seen rather numerous illustrations of the principle that when carcinoma develops in precancerous lesions the change may be sudden and the progress of the new lesion rapid. It appears that the precancerous lesions that become cancerous may reach the malignant form early in the course of the precancerous disease or without a period of slowly developing malignant properties. Hence there is no uniform relation between the progress of chronic mastitis and the resulting cancer and some chronic cases becoming established on a benign basis maintain that character throughout. Perhaps equally important as an explanation of the sudden unfolding of malignant characters is the release from mechanical pressure which proliferating cells experience when they once break the barrier of basement membrane.

The above conceptions may be elucidated by the diagram.

None of these considerations seems to me to seriously affect the interpretation of precancerous lesions as a preliminary stage of mammary carcinoma. Morphological and clinical studies as well as theoretical data accord in supporting this interpretation. There are other ways in which mammary cancers develop, but this is one and probably the most frequent. Clinical observations bearing on precancerous conditions in other organs have been presented at sufficient length to show that the breast is not peculiar in this relation but that the development of cancer from precancerous lesions is a principle of wide application. In each organ, however, the details of the changes from harmless to malignant epithelial proliferation are peculiar and require study and interpretation by themselves.

Important practical results follow acceptance of the doctrine of precancerous lesions. If inoperable advanced cancer is incurable, and localized cancer eradicable, the disease is preventable by dealing



1. Cases passing rapidly through the intermediate period of atypical or precancerous changes. 2. Prolonged period of precancerous changes with slowly progressing carcinoma. 3, 4, and 5. Rapid development of carcinoma or well established mastitis. 6. Late appearance of precancerous changes. 7. Prolonged chronic mastitis remaining benign.

with its preliminary stages. Precancerous lesions are not cancer. Practically they differ enormously from the established disease. They can usually be removed by trivial or safe operations, and they are sometimes amenable to less violent treatment. The therapeutic problem of dealing with cancer, as it were, before it exists, has made far greater progress than the doctrine of precancerous lesions. Gastric ulcers, lingual warts, fissures, and placques, eroded cervices, pigmented moles, and benign tumors, are everywhere excised, with the conviction that a malignant tumor may thereby be prevented, but the relation between the benign and the malignant process is still under discussion and often frankly doubted.

In the breast the therapeutic problem is unusually complex.

Although the majority of mammary cancers arise in previously altered breasts the preliminary changes often fail to attract the patient's attention. Yet there is a large group of cases which present lumps, nodules, cysts, and thickenings requiring diagnosis and treatment. While the decision in these cases belongs to the surgeon, the observations of the pathologist have an important bearing in this field. In general I think it may be said that gross and microscopical study tends to emphasize the dangers of benign tumors and chronic inflammations of the breast. The local removal of fibroadenomas, especially in young women, can be fully justified by the intact conditions generally found in the remaining portion of the organ. In older women I find these tumors more often multiple and associated with chronic mastitis, and in some cases carcinoma has developed after excision of wholly benign fibroadenoma. Its sources in these cases are not clear. Simple cysts in otherwise normal

breasts often spontaneously regress, but I find no adequate clinical study of the subsequent course of these cases.

A group of cases presents nodular thickening of one segment only, of the breast, partial chronic mastitis, and there are numerous records of the successful removal of the diseased segments. There are also numerous cases in which carcinoma has developed in the remnants of such breasts, or in the other breast. I have observed three fatal cases with this history. Hence partial extirpation for chronic mastitis must be regarded as only partial insurance of the life of the patient. The best procedure in these cases may be determined by the possibility of closely following the condition after operation. The practise of excising small portions of the breast and submitting them to hasty study by frozen sections, while not without value, is fraught with danger. The pathologist can pass only on the material examined, not on the whole breast. If any operation is performed on an indurated or cystic breast the whole affected area or the whole breast should be removed. The subsequent procedure can then be determined almost invariably by minute gross examination.

The treatment of established chronic mastitis when the condition can be recognized as such by clinical examination has not yet become uniform. Delbet appears to represent the practice of French surgeons in pronouncing the disease benign and not requiring radical treatment. He recommends that a strict watch be placed over these patients and believes that a malignant transformation can be detected in its early stages when operation is almost surely curative. Baumgartner only partially dissents from this view. Yet French observers first pointed out the dangerous tendencies of the disease and Cornil emphasizes them in his recent work. The treatment recommended by Delbet—compresses, incisions, and iodine injections—is ineffective, and the condition tends to become an increasing burden to the patient. The late stages even of the benign cases described by Billroth are suspiciously like scirrhus carcinoma.

In America I judge that surgeons are more and more inclined to believe, if not fully agreed, that diffuse chronic mastitis demands radical treatment. In 1905 Warren devised for this purpose the operation of plastic resection of the breast, leaving skin and nipple, and this mode of dealing with the disease, with appropriate restrictions, was fully endorsed by Gibson, not only for pronounced chronic mastitis, but for many benign tumors which are often associated with mastitis. While some unnecessary surgery may thus be done I think the study of precancerous lesions in this organ fully justifies the radical procedure.

Presarcomatous Lesions.—The occurrence of atypical productive inflammatory changes leading to sarcoma is not as widely recognized as are precancerous lesions, but is fully in accordance with established views regarding the nature of sarcoma. In fact, many sarcomas show such marked resemblance to inflammatory diseases that pathologists have long been prepared to accept, in a certain sense, the inflammatory or even the parasitic origin of certain sarcomas. The lymphosarcomas especially stand to-day in this position, and Borst among others anticipates the ultimate identification of this group of neoplasms with the infectious granulomas.

Relation of Tuberculosis and Syphilis to Lymphosarcoma.—That tuberculous lymphadenitis may pass rapidly or after several recurrences into lymphosarcoma has been long indicated by clinical observations. Ricker, in a case terminating after fourteen years, found frank tuberculosis associated with lymphosarcoma of neck, lung, adrenals, and spinal cord. Muller saw general sarcomatosis from a primary tumor of the breast, miliary tubercles being nearly coextensive with widespread sarcomatous tumors. Brandt described a case of apical tuberculosis with sarcomatous invasion of ileocecal region, pharynx, parotid, adrenal, and ovary. Inoculation of this pure sarcomatous tissue gave hyperplasia of intestinal follicles in guinea pigs, but inoculation of the tissues of these follicles gave frank tuberculosis in a second series of guinea pigs. Tuberculous intestinal ulcers associated with sarcoma of mesenteric and retroperitoneal nodes is described by Nothnagel, Freudweiler, and Munk. Since the discovery of tubercle bacilli in pseudoleucemic tissues by Weigert; in pure lymphoid hyperplasia by Brentano and Tangl; in generalized lymphomas of nodes, spleen, liver, and serous membranes by Sabrazes, only a slight difference has appeared to separate certain lymphosarcomas from the immediate or distant presence of tubercle bacilli or their toxins. Probably other infectious granulomas may also hold a similar relation, and various miscellaneous and undetermined infectious processes have apparently given rise to the disease.

The transformation of Hodgkin's granuloma into sarcoma has now been fully traced by several observers (Yamasaki, Karsner, Welch). In Welch's case the first nodes showed atypical tuberculosis or Hodgkin's granuloma, but when the patient died two years later there were sarcomatous tumors of lung, liver, and spinal dura. The transformation usually occurs in the late stages of the granuloma, but in a recent study I pointed out that tumors identical in structure with those following Hodgkin's disease are observed in sarcomas of recent origin and limited to the axilla.

In this study was reported a case of cervical tumors, probably tuberculosis, recurring four times in six years and terminating with the picture of endothelioma of lymph nodes. In this study it was also shown that an infectious granuloma, probably tuberculosis, may cause proliferation of the reticulum cells producing the large cell lymphosarcomas, or of the lining endothelium of the lymph sinuses producing a series of endotheliomas of lymph nodes.

The difficulty of distinguishing certain late syphilitic lesions in muscle and bone, socalled "sarcoma syphiliticum," is mentioned by many authors, and especially by v. Hansemann. The recurrence after operation, multiple appearance, and resistance to treatment also complicate the clinical diagnosis. While the active stages of these lesions strongly resemble spindle or round cell sarcoma, they tend toward necrosis and cicatrization, rather than to progressive growth. That true sarcoma may develop from such lesions seems quite possible, but satisfactory proof of this transformation is lacking.

In the healing of fractures and of wounds of the periosteum the histological picture usually shows very marked overgrowth of regenerating capillaries, bone, giant, and connective tissue cells, and resembles the structure of sarcoma. I have observed chronic processes of this type in which it was impossible to determine whether one was dealing with

inflammatory or regenerative overgrowth or early sarcoma.

Traumatic myositis ossificans appears to occupy a position intermediate between inflammatory and neoplastic processes (Berndt). The clinical history of established cases is that of a self-limiting productive inflammation, but the histology of the early lesions may be difficult to distinguish from bone sarcoma. It appears quite possible that the division of cases is accidental, some of the early lesions progressing as myositis, others as traumatic sarcoma. In a case studied in this laboratory and published by Coley the two conditions were combined. Kolisko finds that osteitis fibrosa may be followed by progressive changes leading to giant cell sarcoma of moderate malignancy.

HEREDITY AND PREDISPOSITION IN LIFE INSURANCE.*

By ARTHUR B. WRIGHT, M.D.,

HARTFORD, CONN.

MEDICAL DIRECTOR, TRAVELERS' INSURANCE COMPANY.

THE attempt to discourse at any great length on such a comprehensive subject seems futile and discouraging at the outset, and this treatise will necessarily touch on only a few phases of the subject with the endeavor to apply the views to the realm of life insurance.

These theories which are at variance with one another are to a certain extent misleading and contradictory; however, there seems to be an underlying thought which appears to be more or less practical. At least one can accept what appears to be based on scientific principles and reject what is impossible to believe. Just how far we should be guided by these principles in life insurance work—that is, in the selection of risks, is also a problem, and it is not the intention of the writer to lay down any well-defined rules or laws in this regard. We are to-day guided to a great extent by our past experiences, or the experience of others, or the combined experience of all, and therefore the query, "Why permit ourselves to be influenced by theories which never have been absolutely proven?"

On the other hand, if *heredity* and *predisposition* are of no value from a medical insurance standpoint, why do we inquire into the family history of our applicants?

What bearing has age and causes of death of parents, grandparents, and near relatives? Why do many companies ask their applicants if there is any record in the family history of insanity, cancer, or tuberculosis? This would indicate that we place more or less importance on this history.

*Read at the 25th annual meeting of the Association of Life Insurance Medical Directors, October 7 and 8, 1914.

There appear to be legitimate grounds for believing that physical or mental qualities or tendencies are transmitted from ancestor to offspring.

Many theories have been handed down to us by early investigators and it would not be amiss to briefly outline a few of these views.

Darwin's Theory is that each of the different cells of the body gives off "gemmules" or germinal particles which are capable of reproducing their kind. This was called the "Hypothesis of Pangenesis." He asserted that numbers of these gemmules are being given off continually from all the cells of the body and circulate through the blood and finally settle down in some part, principally in those regions in which the development of offspring will take place later on, *i.e.* buds or germ cells. As gemmules from all the cells of the body are aggregated in these cells, they invest the latter with the power of developing into a new and complete organism.

He also believed that the germ was not exclusively composed of gemmules derived from the organism in which they were formed, but consists at the same time of a very large number of gemmules which are derived from parents and ancestors even of very remote generations. It was also asserted that on account of each cell being represented by a great variety of gemmules a selection must take place. As only one gemmule can form the required cell, the rest must remain dormant.

Therefore, according to his theory, a number of gemmules which have remained dormant are transferred from one generation to the next. These, under certain conditions, become active and bring into existence ancestral traits which had disappeared in the parents. This explains, according to his theory, the variations in individuals of the same race, type, or species and through this selection there is a survival of the fittest.

Weissmann's Theory is a continuity or immortality of germ plasm. He maintained that germ substance is directly abstracted from the developing ovum and preserved without essential alteration to become, by giving rise to sexual elements, the germ substance of another generation, by the corollary that the whole nature of the animal or plant depends upon its germinal substance, and that the resemblance of the offspring to the parent is due to every gonoblast containing some germinal matter.

According to Weissmann, the cells of the embryo are separated into two kinds: (1) The germ cells which become sexual elements, and (2) the somatic or body cells used as building material (Somatoplasm) of the individual.

Naegele's Theory resembles Weissmann's to a certain extent. He believed that the formative force resided in a specific material substratum called "idioplasm" which was essentially identical with Weissmann's "germ plasm." This "idioplasm" was claimed to be the nuclear substance and the essential factor in the function of heredity, and the nucleus, therefore, the organ of hereditary transmission.

De Vires' Theory was called "Intracellular Pangenesis." This was to the effect that the nuclear substance of the germ plasm was composed of minute particles which he called "pangenes," which were not cells but the bearers of the properties of the cells. The entire cell he called the "Protoplast," and its independent parts "Pangenes."

In the nucleus he claimed were nuclear rods which he also called *idants* and *chromatin* rods, which are composed of an ancestral plasm which he called *ids*, each representing "an individuality."

He also maintained that the doubling and multiplication of these *idants* prior to fertilization explains the variety or variation of form and character of the subsequent individual.

Galton accepted the theory of "gemmules" but rejected the idea of Darwin that they circulated through the blood and that the "gemmules" compose the germ cells.

Mendel believed that every organism is made up of *determinants* in which are contained an aggregation of characteristics and dominating traits that have been inherited from a previous generation. He also maintained that there were organisms of the same species in which the dominant type was absent or deficient. This was called by Mendel a *recessive* type. If two dominant types are crossed, the result will be a generation of the same dominant type. However, if a dominant type is crossed with another of the same species which has but a single *recessive* characteristic, the result will be that 25 per cent. of the succeeding generation will be of the *recessive* type and 75 per cent. of the *dominant* type, though not in the same degree. Also, if one of the *recessive* type mates with another of the same type, all of the succeeding generation will be *recessive* or defective.

The views of these early investigators are somewhat complex and some of them would not stand the strictly scientific test; however, they all show considerable study and we cannot help but feel that they have all benefited science.

Their work was progressive and many of the main principles are accepted at the present time. Whether or not we call the agent through which the characteristics are transmitted, "gemmules," "germinal particles," "cells," germ plasm," "determinants," "idioplasm," or what not, the principle is the same, and whether or not these circulate in the blood or by just what process the result is brought about, may never be proven, and, in spite of a certain amount of scepticism, we are compelled to believe there may be some truth in these views.

A recent article appeared in the MEDICAL RECORD by Dr. Thomas E. Satterthwaite of New York on "Some Problems in Genetics." He believes that matings of any sort should be amenable to some sort of regulation, by medical, legal, moral influences or otherwise. He cites the notorious Jukes family and the liberty is taken of quoting from this article in regard to this family:

"Somewhere between the years 1720 and 1740, a hard drinking backwoodsman of our State, known to us as Max Jukes, was the first in a family that up to the year 1877, either in direct or collateral lines, by marriage or cohabitation, numbered upward of a thousand individuals. Of these, 709 were actually traced in the course of their investigation. Three hundred or thereabouts were computed to have died prematurely; 50 of the females were common prostitutes; 40 of the women had specific diseases, contaminating 440 persons; 60 were habitual thieves; 7 were murderers, while very many others were in various ways burdens on the State. When the inquiry closed in 1877 it was estimated that the family had cost the State $1,308,000, or more than a thousand dollars apiece for each of the 1,000 persons in whom there had been Max Jukes' blood, besides causing widespread degradation and

the physical harm to the community that has been described."

He also outlines the history of the Kallikak family: "Back in Revolutionary times a man by the name of Martin Kallikak took advantage of a feeble-minded girl. Of their 480 descendants, 143 were feeble-minded, the greater part of the number falling below mediocrity, while none of the remainder had any special ability. Later Kallikak married a respectable Quaker girl, 'of good ancestry,' it is said. From this union there were 496 descendants whose histories were traced. All of these but two were normal mentally, and the two exceptions were not feeble-minded."

Within the past few months the *Literary Digest* commented on an article written by the physician in charge of the Indiana State Prison. This physician has made a study of moral defectives and maintains that certain persons exist, not insane nor otherwise abnormal, who simply are unable to refrain from crime because of defective nervous organization. This condition he calls "Constitutional Immorality" and prefers this name to "Moral Insanity" or "Moral Imbecility."

A quotation from this article is as follows: "These unfortunate moral defectives we generally find to be burdened with an evil heredity, a harsh, unrelenting tyranny of ancestral defect. Many of them are ignorant and do not rise above the level of the feeble-minded; in marked contrast others are highly educated persons who assent to the general propositions concerning right and wrong, and frequently delight to discuss moral customs and laws in order to exploit their casuistic and argumentative powers, but to them the concrete application or moral or legal restraint is a hardship which they cannot understand."

This physician evidently believes in heredity and predisposition as regards defects in the moral make-up of certain persons and his statements certainly appear to be worth considering, and while there is "a cast wealth of clinical material of psychiatric nature going to waste in our penal institutions because of a lack of scientific curiosity on the part of well qualified investigators," we are compelled to believe there is an element of truth in the theory.

It is stated there are many infirmities that may be inherited, such as epilepsy, chorea, deafmutism, and various mental disorders. It is also asserted a person afflicted with any of these who mates with another similarly affected will, under certain circumstances, transmit them to the offspring, who will in turn hand them down to succeeding generations.

Karl Pearson claims that statistics prove that 75 per cent. of all deaths are due to inherited diseases. If this is true, family history certainly is an important factor in the selection of life insurance risks.

Dr. Paul Waterman of this city presented an able paper on "Heredity" before the Hartford Medical Society on May 18 this year. With his permission the following is quoted: "A selective death rate means that a certain proportion of a community or species in any given generation will die as the result of constitutional causes, as the result of weakness or susceptibility inborn in the individual. As long as the environment of the species remains constant the value of the selective death rate is unity or 100 per cent. As conditions of environment change, its value is lessened, and at present for civilized communities it is assumed to be between 50 and 75 per cent. In fact, extensive statistics have placed it at 60 per cent. Our present environment, working chiefly through the forces of sentimentalism and democracy, has tended very markedly to diminish this value still further because we do our utmost to protect the weak from death. This procedure would impose its additional burden on each generation, but without any marked cumulative effect on succeeding generations, if it were a fact that all types or classes of human beings were equally fertile, if each group according to its fitness produced an equal number of offspring with every other group; but this does not seem to be the case, because it appears that the fitter stocks are less productive at present, that the less fit or unfit stocks are more fertile, and when we add to this the fact, or what appears to be a fact, that 12 per cent. of those born in this generation will produce 50 per cent. of the members of the next generation, we can realize that we are facing a theoretical degeneration rather than an evolution."

The Doctor has two suggestions which he concedes are difficult to put into practice; first, to eliminate the unfit by segregation; and, second, to stimulate the procreation of the fit. It cannot be denied that some such procedure would be of benefit to the race in general and would result in a lowered mortality, but whether or not this is feasible is left for your determination.

As far as eugenics is concerned only a few words will be submitted. It would appear to be a problem which, up to the present time, remains unsolved. Numerous suggestions have been presented and it is not unreasonable to suppose that legislation may deal with the matter to some extent in the future. In fact there has recently been an effort to prevent the propagation of the feeble-minded. The sexual instinct in this class is greatly developed and, having no particular sense of responsibility, they increase rapidly.

Dr. Victor Vaughan says: "There must be laws governing and preventing the marriage of the unfit."

The principles of practical eugenics up to the present time seem to result in two schemes: the first, which proposes to better the race by breeding of individuals who are free from any defective strain; and, second, to prevent the mating of two defective strains.

We will, however, leave this matter to be solved by those who are particularly fitted, by devoting their time, energies, and investigations in that direction.

In the *Encyclopedia Britannica*, under the "Empirical Study of Heredity," appears the following: "The fundamental basis of heredity is the separation of a mass from the parent (germ plasm), which under certain conditions grows into an individual resembling the parent. Every character found in a parent may or may not be present in the offspring. When any character occurs in both it is generally spoken of as transmissible and of having been transmitted. In all kinds of reproduction the characters of the class, family, genus, species, variety or race, and of the actual individual are transmissible. The transmitted characters are anatomical down to the minutest detail; physiological, including such phenomena as diatheses, timbre of voice, and peculiarity of handwriting; psychological, pathological, teratological, such as syndactylism and all kinds of individual variations.

Either sex may transmit characters which in themselves are necessarily latent—as, for instance, a bull may transmit a good milking strain."

Also it is stated that (1) a child may inherit the anatomical constitution of either parent and with that a special liability of failure to resist the attacks of a widespread disease; (2) the actual bacteria may be contained in the ovum or possibly in the spermatozoon; and (3) the toxins of the disease may have affected the ovum, or the spermatozoon, or, through the placenta, the growing embryo.

In the first two cases the offspring cannot be said in any strict sense to have inherited the disease. It is also stated that "these two, heredity and environment, are the master influences of the organic world." There would hardly appear to be any doubt that some diseases are passed on from one generation to another. This, however, in some cases cannot be claimed to come under the domain of heredity, but, more strictly speaking, is an infection of the parental germ cell.

Syphilis is the main and prominent disease which falls in this class. Other diseases, such as carcinoma, epilepsy, etc., have been claimed to belong to this class; however, we cannot say positively that such is the case owing to the failure of laboratory experiments to prove it.

As regards tuberculosis, it cannot be claimed that the disease is hereditary, as was once supposed. It is claimed, however, that the transmission of abnormal predispositions and the infection of the germ might combine to bring about the transference of this disease from one generation to another.

We therefore see how closely heredity and predisposition are allied.

There appears to be an inclination on the part of life insurance workers to attach less importance than formerly to a family history of tuberculosis, and in a paper produced by Dr. Symonds two years ago, it was shown by actual experience that at certain later ages it could be disregarded altogether. The time has not come, however, when the majority of life companies entirely disregard it in the earlier ages.

If our ideas change from time to time, it would seem to be merely following the laws which have been worked out by these early investigators. Darwin and others claimed that environment played an important part and, in regard to tuberculosis, this may be the essential feature which seems to lower the mortality. And, again, in the selection of life insurance risks, there is a real selection.

In scrutinizing an applicant for life insurance, we would look with doubt on one who admitted tuberculosis in the family history, who was considerably under weight, fragile, and who did not manifest ordinary resistance. It would indicate to our minds that this individual inherited the anatomical constitution of a parent, and we would be inclined to believe that there was a special liability of failure to resist the attack of the disease.

Then why is there a disposition to be more liberal as regards family history? Environment would be one explanation, and that means education.

As stated above, we do our utmost to protect the weak from death. We know more about tuberculosis than we did fifty years ago. Science has done a great deal for us. We do not consider an individual who suffers from incipient tuberculosis as doomed. In companies that accept sub-standard risks, there is a large class of these so-called "arrested" or "cured" cases and the experience on these has been favorable. This shows what environment and education will do and would hardly seem to prove that the laws of heredity and predisposition are entirely upset.

Then, again, we accept only the very best of risks submitted. There is, as has been said before, a real selection. Only the more robust and those who manifest a power to resist disease are accepted. This does not prove that the predisposition is not present. It would merely seem to indicate that by education the lay people at large have progressed and that more stress is put on environment, mode of life, proper food, habits, and those matters which tend to a betterment of their general welfare.

These may be the factors which tend to lower the mortality.

A family history of other diseases, such as mental and nervous disorders, early deaths in the family from apoplexy or other degenerative disease, still plays some part in the selection of risks.

Whether or not medico-actuarial figures show a lessened mortality over figures in years gone by, that alone would hardly prove that there is nothing in heredity or predisposition; on the other hand, it might prove that we are improving in our method of selection, also that environment is an important feature. We cannot entirely disregard the theory that "like begets like." The history of the Jukes family would tend to prove something.

We much prefer that the risks we accept show no history of tuberculosis, insanity, suicides, early deaths from apoplexy or degenerative diseases in their families.

What conclusions can be derived from the above and can these ideas be applied to the realm of life insurance?

We are guided to so great an extent at the present time by experience and actuarial figures that there may be a disposition to disregard everything else.

Whether or not we claim to believe any of the above theories, we unconsciously show our inclination to place some importance on the main principle of heredity and predisposition by the manner in which we scrutinize and delve into the family history. We are not compelled, however, to believe that because a parent died from tuberculosis the offspring must do likewise. We are led to believe that no microbic disease is hereditary, and the reappearance of the disease in the next generation may be due to an infection of the germ or germ plasm, so-called, or, in other words, the process is started before the offspring is born.

It can safely be said that the inheritance of a predisposition to a disease is not inheritance of the disease. Heredity than appears to be secondary to predisposition so far as transmission of disease is concerned, in as much as we inherit predisposition rather than disease. We inherit anatomical and physiological characteristics and in this manner are predisposed to disease. This appears to be the limit of heredity, according to modern thinkers, and to that extent only can it be applied to the realm of life insurance and the selection of risks.

Predisposition is difficult to define; however, we may illustrate by stating that the body is a machine which is made up of delicate parts.

If all the parts work in harmony, there is a good working machine, which gives promise to run the allotted time. However, if some of the delicate

parts are defective, there is friction which would indicate that the life of the machine is limited. These delicate parts are the anatomical characteristics which we inherit and upon them is computed the period of existence. Therefore, if there is not harmony of the parts, there may be a predisposition to disease. In other words, we may say such individuals lack resistance. In our selection of risks, therefore, predisposition has been in the past and still continues to be a factor.

As stated before, environment is an element which at times appears to offset and upset the laws of heredity and predisposition; however, not to the extent of defying the main principles, which will probably stand the test for a considerable time.

The writer does not wish to convey the idea that he is a disciple of any particular doctrine or creed, nor can he claim to have thoroughly covered such an exhaustive subject in such a brief treatise; however, certain principles are accepted by all investigators in this line and appear to be of some value to workers in life insurance.

CHRONIC PROSTATITIS AND ITS TREATMENT BY THE GENERAL PRACTITIONER.

By WILLIAM J. ROBINSON, M.D.,

NEW YORK.

CHIEF OF THE DEPARTMENT OF GENITOURINARY DISEASES AND DERMATOLOGY, BRONX HOSPITAL AND DISPENSARY; EDITOR OF THE "AMERICAN JOURNAL OF UROLOGY, VENEREAL AND SEXUAL DISEASES," "THE CRITIC AND GUIDE," ETC.

CHRONIC prostatitis is a very common condition. In a greater or lesser degree it is present in a very large percentage of the male population of every civilized country.

Causes.—One of the most important factors in the etiology of chronic prostatitis is gonorrhea, but gonorrhea does not play the same relative rôle in the causation of chronic prostatitis that it does in the causation of acute prostatitis. In the latter gonorrhea is by far the principal factor; other causes play but a subordinate rôle. This is not so in chronic prostatitis; while, as we said, gonorrhea does play a very important rôle, other factors are also of great importance. Among those factors we may enumerate chronic urethritis of whatever origin; masturbation; sexual excesses (that is, too frequently repeated natural sexual intercourse); coitus interruptus; complete abstinence, particularly if accompanied with excitation, mental or physical, without gratification (it is remarkable how the over-use, abuse, or non-use of a function frequently leads to the same result); a steady, long-continued sedentary life; catheterization; stricture, and long-continued cystitis.

A chronic prostatitis following a gonorrhea, or other forms of urethritis, may be chronic from the very start or it may be the end stage of an acute or sub-acute prostatitis.

Symptoms.—The symptoms of chronic prostatitis may vary from the mildest to extremely severe. There are cases of prostatitis which are symptomless, or practically symptomless, and there are cases which assume the character of a very serious malady.

It might be asked how we know that a man has prostatitis if it gives him no symptoms whatever. Of late years a good many men before getting married, or even before becoming engaged, come to the physician for a sexual examination. They tell him that they feel all right in every way, that there is absolutely nothing the matter with them, but that they want him to make sure that they are all right. Some of them may have had a gonorrhea, some of them have absolutely no venereal history. In a certain percentage of these men who complain of no symptoms whatever we find on examination distinct evidences of prostatitis. The prostate is either enlarged and "boggy," or only boggy, and on expression we obtain a fluid which gives unmistakable evidences of a mild grade of inflammation.

Pathologically, the condition in the prostate may vary from a simple congestion to an extensive suppuration. In the majority of cases, however, the symptoms of prostatitis are pronounced, and may be classified as local, sensory, urinary, sexual, and general nervous.

The *local* symptoms are those that we discover by an objective examination. The prostate is usually enlarged, soft, boggy; either soft throughout or soft in some spots and hard and nodular in others, more than normally sensitive on pressure, and exudes a turbid lumpy secretion on expression.

The *sensory* symptoms are heaviness and a dragging sensation in the perineum, pain in the prostate and perineum, and pruritus ani or itching around and within the anus. The patient cannot sit comfortably for any length of time in one place and likes to shift his position. A symptom that can be frequently observed by the careful observer is that the patient when sitting down will sit on the edge of the chair, and if the chair permits it, on one buttock only. Walking is less annoying to him than sitting or standing. He feels most comfortable lying down. While the pain may be limited to the prostatic region, it may, as is easy to understand with an organ so rich in nerves as the prostate, radiate to various parts of the body, to the testicles, urethra, penis, thighs, and small of the back. The pain may also radiate to the kidneys and simulate the pain of renal colic. Personally, however, I have not seen such cases; in renal colic the pain is too acute, too sharp, to be mistaken for the dull, gnawing pain of prostatitis. Still some authorities claim to have seen such cases.

A very frequent and most annoying symptom is a leaden heaviness in the calves of the legs, and also a burning in the soles of the feet. These symptoms make themselves particularly noticeable in the afternoon, around four o'clock. I have been able to diagnose prostatitis in a great number of cases from these two symptoms alone. With the cure of the prostatitis these symptoms disappear.

The Urinary Symptoms.—One of the most common symptoms is the *frequency* of urination. The patients may have to urinate every two hours or every hour, and if they happen to drink some irritating liquid like beer, may have to urinate every fifteen or twenty minutes. They also have to get up in the night from one to four times. Another symptom is the urgency of urination. There is a difference between frequency and urgency. A person may feel like urinating frequently, but if he is unable to urinate at a certain time it may cause him no effort to retain his urine; in the case of urgency, however, when the desire to urinate comes on it must be complied with instantly or the patient is apt to wet his underwear. There is a disagreeable, perhaps scalding, sensation on urinating, and there is dribbling of urine after the act. The size and character of the stream is often unaffected, though as a rule it is smaller than usual. The

urine itself is frequently turbid, and contains many bacteria and a large amount of phosphates; in fact, *phosphaturia is one of the most common symptoms in prostatitis.* Whether it is a direct result of the prostatitis or whether it is caused by the nervous condition induced by the prostatitis is an open question.

The *sexual* symptoms are briefly summarized in imperfect erections and premature ejaculations. The libido may be diminished, but as is so often the case whenever any irritative condition exists in the prostate, maye be greatly increased, causing the patient to indulge to excess, thus still further aggravating his condititon.

The *general* and *nervous* symptoms produced by an irritated or inflamed prostate are literally legion. First there is a general irritability, a physical and psychic irritability. The patient responds much more quickly to external stimuli, such as changes in temperature, and he gets very easily upset over little things. Then there is a general depression. This depression expresses itself not only in a lack of desire for work and a lack of interest for things, but in a general despondency. The patient may occasionally become deeply melancholic, and this to such an extent that he may harbor suicidal ideas. If the condition lasts long he may become a victim of sexual neurasthenia, with its legion of symptoms, but to discuss the latter here would lead us too far and we must refer the reader to special books on the subject.

Treatment.—While prostatitis, as we have seen, may be a serious complication, giving rise to numerous annoying symptoms which make the patient wretched, diminish or destroy his usefulness, and may even lead him to suicide, there is one bright feature about it, and that is that it is very amenable to treatment.

While we may not change the secretion in a suppurating prostatitis to such a degree that it does not contain a single pus cell, still practically all cases of prostatitis (and it is quite safe to leave out the word practically) may be improved to such an extent that they will give no symptoms and the patient will not be aware of their existence.

The treatment of prostatitis, as of all diseases of the genitourinary organs, is both general and local. The patient must guard against constipation. The diet must be bland, strong spices and condiments being eschewed, alcoholics must be reduced to a minimum, and everything must be done to raise the general condition of the patient from below par to par or above par. Cool baths and douches are useful for the general system, but hot sitz baths are necessary for the prostatic condition. It goes without saying that any pathological condition in the urethra, such as a posterior urethritis, or a stricture, or colliculitis, or a seminal vesiculitis, must be treated concomitantly.

Prostatic Massage.—There is one measure, however, which is more important in the treatment of chronic prostatitis than all other measures combined, and that is massage of the prostate.

It is quite remarkable what rapidly beneficial effect a massage of the prostate will produce on the patient's condition, both local and general. It constitutes one of the most gratifying methods of treatment in the venereal specialist's work. Without the patient being told what the massage was for, what it was expected to accomplish, he will either at once or at the next visit volunteer the statement that he felt immediately better, that not only did he feel an improvement within the rectum and perineum, but he felt generally better. In fact, even a mere examination of the prostate, in which you sweep the finger around the gland to determine its contour, size, and consistency, and in which you do hardly any expression, produces a beneficial effect. There is no exaggeration in saying that the effect of prostatic massage is often simply marvelous.

While we are more interested in facts and in the effects of certain treatment than in the explanations of the why and wherefore, still the reasons for the strikingly beneficial effect of prostatic massage have always been of great interest to us. And while we can pretty well explain the rationale of its action, further studies on the subject are certainly in order. Some reasons of this beneficial action are self-evident. Where the prostate contains a large amount of catarrhal or purulent stagnant secretion, the mere mechanical removal of this mass, which diminishes the size of the organ, relieving pressure on neighboring organs and nerves, is beneficial. Then the massage itself and the removal of the secretion improves the circulation in the prostate and in the periprostatic veins and lymphatics. It tones up its musculature so that new blood reaches its various recesses, and its tissue, as well as its numerous nerve plexuses, become better nourished.

Technique of Massage.—The way to perform massage properly and effectively is to have the patient, standing with his legs well apart, bend over a chair or the examining table, firmly supporting himself with both hands. The index finger of the gloved hand, over which an extra finger-cot may be put on, well annointed with petrolatum, (for rectal examinations I prefer petrolatum to the water soluble lubricants) is introduced gently into the rectum, and the prostate is gently but firmly massaged, first from the right side toward the median line, then from the left side toward the median line, then a few firm, pressing strokes are made from above downward. Special pressure is applied to any indurations that may be encountered, or to any specially soft spots.

When the massage is completed the patient is told to get up gradually and slowly from his stooping position, and is given a glass to urinate in. The urine washes away the prostatic secretion.

This is for ordinary cases where there is little discharge, and that chiefly catarrhal. But where there is much discharge and of a purulent character, it is best to have the patient urinate first, then fill his bladder with a 2 per cent. boric acid solution, then massage him, then tell him to urinate, and after he urinates it is well to instil into the bladder a dram or two of a 1-1000 solution of silver nitrate, instilling a few drops of the same solution throughout the urethra. This is to prevent any infection from the prostatic secretion.

Massage in the Horizontal Position.—Some physicians perform prostatic massage with the patient lying on his back, or even on his side. I am opposed to this position, because it is much more unsatisfactory than the standing-stooping position. The finger can never reach quite as far with the patient lying down as with the patient standing up and pushing his prostate against the finger. Nor can the physician's finger ever get such a leverage with the patient in the horizontal position as when the patient is standing. For the mere purpose of examination the recumbent position may be suffi-

cient, and when the patient is of an extremely nervous temperament, subject to fainting spells, that position must sometimes be chosen, but it is never the position of choice, and we can never be sure of giving the patient a thoroughly satisfactory massage in that position. Another point, perhaps not of so much importance, but still of some importance, is that when the patient is stooping down, the secretion, through gravity, has a tendency to run out of the urethra; in the recumbent position it is sure to flow back into the bladder.

Abuse of Prostatic Massage.—There is no therapeutic procedure, beneficent as it may be, that cannot be abused or overdone. This is true of massage. Useful as it is, much damage may be done by it if it is performed too brutally or too frequently.

There must never be a digging of the finger tips into the prostate; there must be only a pressure with the entire palmar surface of the finger. Too much force must not be used, or the inflammation instead of being allayed may be increased in severity, or even necrosis may be caused. Nor must the massage be performed too frequently, but here no dogmatic statement can be made as to what constitutes frequency. Some patients can stand massage every other day, some only once a week or once in ten days.

Massage must not be performed when there is acute inflammation in the prostate or an acute exacerbation of a chronic inflammation.

Besides the aggravation in the condition of the prostate itself that the too frequently or too brutally performed massage may cause, it may also cause an epididymitis, a seminal vesiculitis, and even sciatica. Not too much zeal in the best of causes!

A Few Minor Points.—1. Some patients come to the office with full recta, the feces pressing on the prostate. This not only makes it unpleasant for the physician, not only interferes occasionally with the proper performance of the massage, but induces in the patient a desire to defecate. Such patients should be told always to empty their bowels before coming to the physician's office. If they cannot do it spontaneously they should take an enema.

2. Where the secretion from the prostate is so profuse as to run from the urethra, the patient is instructed to support himself with one hand only, holding in the other hand a small glass under the penis to catch the secretion.

3. Be on your guard and watch your patient very carefully when giving him the first massage, for some patients faint after the first massage. Let the patient get up from his stooping position very slowly, make sure that he is not pale, and that he has no sensation of fainting. If he complains of a sense of weakness the best thing is to lay him down on the examining table or couch for a few minutes.

4. In some obstinate cases of prostatitis I have found the introduction of a potassium iodide-iodine suppository (see No. 2 of the formulas below) followed by a gentle massage for 5 to 7 minutes very beneficial. The massaging apparently causes a much greater absorption of the K I and iodine than a mere introduction of the suppository.

Hot Rectal Douches.—Another useful measure, but altogether secondary to massage, is the application of hot water to the rectum by means of one of the numerous prostatic psychrophores. This may be done two or three times a day for about fifteen to twenty minutes each time. The psychrophore is best given into the patient's own hands and he is shown how to use it.

The hot rectal tube applied for about fifteen minutes before prostatic massage makes the latter more efficient, permitting us to express the secretion more readily. Suppositories of various composition, the formulas for which will be found below, also form occasionally a useful aid in the treatment. A morphine and belladonna suppository inserted by the patient before he comes to the physician's office is useful in allaying the irritability and making the prostate less sensitive, and thus permitting us to manipulate it more efficiently than we otherwise could.

℞ Iodoformi, gr. i
Morph. sulph., gr. ¼

℞ Morph. sulph., gr. ¼
Ext. belladonæ, gr. 1/6
Ol. theobromæ, gr. xxx

Where a psychrophore and the apparatus necessary to run a current of hot water are not obtainable, the patient may inject into the rectum 6 to 8 ounces of hot water, as hot as he can bear it, and retain it for about ten minutes. Instead of hot water a saline solution, or a saline solution with 5 grains of antipyrin and 5 grains of laudanum, is often preferable. It is, however, well to bear in mind that some recta cannot bear repeated hot-water injections without severe irritation, and they cannot be continued for any length of time. The rectal psychrophore, however, can be borne without irritation.

Atony of the Prostate and Prostatorrhea.—There is a condition of the prostate which deserves consideration by itself, under a separate subdivision. It is not an inflammation of the prostate and no inflammatory products are contained in its secretion, but the whole prostate seems to be relaxed, atonic, and this condition is best described as atony of the prostate. Its ducts are dilated and on mere touching of the prostate with the finger a large amount of prostatic secretion oozes out from the urethra. The secretion may be quite normal or somewhat catarrhal in character. The symptoms of atony of the prostate, however, are the same as of the other forms of prostatitis, except that the sexual features are more markedly exaggerated. Particularly is premature or precipitate ejaculation a prominent symptom. Prostatorrhea is simply a further stage in the development of prostatic atony. In prostatic atony the application of the finger produces a discharge of secretion, in prostatorrhea the prostatic secretion runs out spontaneously or at the end of micturition (prostatorrhea mictionis) or after defecation (prostatorrhea defecationis).

The treatment of atony of the prostate and of prostatorrhea is in general the same as of the other forms of prostatitis. Massage plays here the same important rôle. But instead of hot-water irrigations or applications, cold water is of more benefit. And it is also in this condition that faradization with the prostatic electrode in the rectum and the other electrode over the symphysis is very useful.

THE QUESTION OF INTESTINAL STASIS.*

By WALTER L. BARBER, JR., M.D.

WATERBURY, CONN.

VISITING SURGEON TO THE WATERBURY HOSPITAL.

I FEEL greatly honored at being asked by your president to read a paper to you on this occasion. I regret that I am not going to introduce much that is either new or original, but I shall endeavor to present a few of the recent teachings along this line. First, I want to present one of my case reports.

CASE.—In January, 1911, Miss M. B., unmarried woman, 32 years of age, came to consult me regarding a chronic dyspepsia. She told me she had no appetite and was always uncomfortable when she ate; and that she suffered from an obstinate constipation. At irregular intervals she had felt twinges of pain in the region of the appendix. She admitted that cathartics, rest in bed, and "restricted" diet always gave her relief, but that upon returning to work her symptoms returned.

Upon examination, I found the patient worn out and emaciated. Her skin was dark—almost dirty—and there were areas of deep pigmentation under her eyes. Her heart, lungs, and pelvic organs seemd normal. Palpation of right iliac fossa gave tenderness on pressure. I watched her a couple of weeks, and at each examination I found tenderness in the same place. I diagnosed a chronic appendicitis and advised removal of the appendix. Upon opening the abdomen, I found a mild catarrhal inflammation, the appendix kinked and slightly adherent to the cecum. Recovery uneventful.

In April, 1912, fifteen months later, this patient came again to see me, reporting an obstinate constipation. Her complaints at this time were: marked distress after eating, indefinite abdominal pains, exhaustion after least efforts, and marked despondency. Her suffering was increased by a progressing arthritis in both wrists and by disturbed vision (in fact, she was wearing glasses). Her operation had not relieved her as I hoped it would, and she was disgusted with me as well as with her life. I now tried proper supports and exercises, as well as free regular evacuations. One year of this treatment showed no improvement.

In June, 1913, this patient went down to New York and consulted Dr. Gerster, by my advice. The *x*-ray plate showed a greatly distended and elongated cecum, reaching into the pelvis. The transverse colon was prolapsed almost to the pelvis. The stomach did not extend below the umbilicus. Dr. Gerster's diagnosis was chronic intestinal stasis. Two weeks later he performed a short circuit operation. The rapidity with which every symptom of her profound toxemia disappeared was spectacular. Her appetite has improved, she has gained in weight, her bowels are regular, and she says she has not a pain or an ache.

This case illustrates well in every detail a profound toxemia of the body tissues, caused by a continuous poisoning. It belongs to a class of cases so often neglected, or else dismissed with attention only to one of the several end results, such as constipation, dyspepsia, or neurasthenia. Here was a case where I had failed to get at the real first cause of the trouble, and its study has brought forth the subject of this paper.

*Read before the New Haven County Medical Association, Waterbury, Conn., October 22, 1914, and by title before the Waterbury Medical Association, February 9, 1914.

Definition.—The term intestinal stasis was first introduced to the profession in 1903 by Sir Arbuthnot Lane of London. He described it as meaning a delay in the passage of fecal material along the alimentary tract, a delay far in excess of the normal twenty-four hours. The next year, 1904, Metchnikoff published his remarkable essay, characterizing old age as a disease originating from tissue poisoning by toxins generated in the gastro-intestinal tract. Both these men began to recognize alimentary toxemia and its evil consequences about the same time. Prior to this the causes of constipation had been little understood and their treatment most unsatisfactory. But with the realization that poisoning results from fecal delay, with the better understanding and knowledge of the relationship of the alimentary tract to the many ills affecting the human body, as brought out by these two famous men, then, and then only, began real scientific investigation concerning the evils of waste retention and waste absorption.

Physiology.—Before we discuss the various theories concerning the causation of stasis, I want to recall to your attention very briefly four physiological facts about the normal alimentary tract which concern us in this subject.

1. The most important part of digestion and absorption takes place in the stomach and small intestines, where normally there should be no putrefaction.

2. Dr. William Mayo was the first to point out the importance of the high fixation at the splenic angle, which acts as a muscular sphincter. This splenic angle divides the large intestine into two portions. The portion of the colon proximal to this flexure concerns us most in the study of stasis, and I want especially to emphasize these points regarding it: The ingesta from the ileum is held back here and churned by an antiperistalsis, which begins at about the middle of the transverse colon and travels backward through the ascending colon and cecum. This allows water and the final nutritive material to be absorbed, and gives this first portion of the colon an assimilative function like the small intestine. There is here an ideal flora for putrefaction and bacterial activity. It is here where most often we find membranes and adhesions and most commonly fecal delay, and it is usually in this very region that the most severe grades of toxemia originate. In the second portion of the large gut, distal to the splenic flexure, waste material travels rapidly and, therefore, bacterial changes and absorption are at a minimum. Here we have a storage house, where delay causes little or no toxemia.

3. The ileocecal valve also plays a very important rôle in the welfare of human beings. History tells us that it was not until 1842 that its double function was recognized, that of a sphincter and of a valve, for it moderates flow into the cecum and prohibits regurgitation. Its integrity is essential to health, and its efficiency is due to the oblique manner in which it enters the cecum.

4. And lastly, I want to remind you that, normally, fecal material is delayed for a definite period at three points in its passage: (1) In the stomach, by the pyloric valve; (2) in the terminal ilium by the ileocecal valve, and (3) in the cecum and first portion of the large intestine by antiperistalsis.

Causes.—For years we have recognized a good many contributory causes of constipation, chiefly dietetic and hygienic errors, as well as the fact that man assumes the erect and sedentary posture during

the greater portion of the twenty-four hours. These faults are common to us all and increase with civilization. But it was Mr. Lane, and about the same time Dr. Robert Morris of New York, who first began to recognize the connection of certain adventitious bands in the abdominal cavity with intestinal delay. Shortly after this Jackson described his famous membrane; then followed Charles Mayo, Gerster, Hertz, and Pilcher, all master minds, in a great international discussion regarding the etiology and relationship of these membranes to stasis.

Mr. Lane's theory is that these bands are evolutionary; that they are Nature's efforts to overcome a constantly overloaded colon. Mr. Lane has pointed out that they are commonly found at certain definite points, namely, at the pylorus, at the duodenojejunal juncture, at a point one to three inches from the terminal ileum, at the appendix, or at any of the regular flexures. The bowel being held firmly by adhesions at a fixed point, tends to drop on either side, producing an angulation known as Lane's kink.

Lane and his followers are firm in their belief that these are not inflammatory but evolutionary, arguing that they occupy definite positions and that their thickest part is always away from the gut.

Other men take the point of view that they are congenital. Pilcher, Mayo, and Gerster regard them as the result of oft-repeated attacks of peritonitis, associated with chronic colitis. Adami proves to his own satisfaction that bacteria penetrate the coats of the intestines, and believes that stasis, through the agency of bacteria, may produce these pericolonic membranes.

However unsettled we are at present upon the actual formation of these membranes, I believe we have reached a certain stage of understanding regarding them, for surely that white fibrous band originating from the mural peritoneum, or that gossamer vascular veil, which Eastman declares to accompany at least 75 per cent. of chronic appendicitis cases, interfere with the fecal stream, whether they occur as a result of stasis or result in stasis. The same relationship exists between ptosis and stasis—when ptosis is present it is almost sure to increase fecal delay—while on the other hand stasis does increase and may actually cause ptosis, for the greatly overloaded colon drags upon its mesenteric attachments until it prolapses. Dr. Eastman in a recent paper has brought out clearly this very interesting relationship between stasis, ptosis, chronic colitis, and adhesions, and to these four conditions I want to add incompetency of the ileocecal valve. Certainly I believe it should be added to these, if we are to believe all the data coming from the Battle Creek sanitarium, which show the proportion of the cases of stasis with an incompetent ileocecal valve as 1 to 6. Briefly, Eastman sums up his conclusions: It appears that each of these elements may cause any one or all of the other four, or may itself be caused by the other four. An intelligent treatment of any or all of these different factors must be based on an understanding of this mutual relationship. These conditions have always been closely associated with the study of stasis and have caused much confusion. It would appear, therefore, that this explanation was both rational and a most helpful advancement.

Symptoms.—The symptoms of stasis are those produced by obstruction, and those resulting from toxemia. In consequence of an obstruction, we have indigestion with more or less indefinite and irregular pain, usually associated with constipation. The character of the pain and discomfort is dependent upon the amount of obstruction, and its locality is most often about the cecum, even as high as the last rib, or it may be over the sigmoid. But these symptoms from the mechanical abnormalities are very trivial as compared with those brought about by the daily absorption of the toxins, which produce such severe poisoning. The clinical picture of such sufferers is well known to all of us—the change of temperament, the inability to concentrate on anything, the marked depression, the countless neurasthenic worries. These patients complain of headaches, loss of appetite, and loss of weight; they are drowsy and often have to lie down during the day. The toxins, in excess, circulate throughout the body and cause degenerative changes in every organ and in every tissue.

I will abstract briefly from Sir Arbuthnot Lane's admirable description of these: Probably the vessels, the liver, and the kidneys suffer the most. The next most conspicuous result is the removal of fat from the body tissues. We see this in the formation of wrinkles, in the marked prominence of the bones, and often in the sagging of the kidney and pelvic organs. The breasts waste and become flabby, and areas of induration in the upper and outer zone are noted, which later show cystic degeneration. These breast changes are so characteristic that they are by many considered a barometer of the degree of stasis. The resistance of mucous membranes is markedly lowered, so much so that organisms easily obtain a foothold and multiply, *i.e.* involvement of stomach, duodenum, bile-ducts, and of pancreas is commonly a secondary result. In the eye, degenerative changes of the cornea, of the lens, or of the muscles of accommodation may occur, while in the joints a chronic rheumatoid arthritis develops. In most cases pyorrhea alveolaris is present.

A world-wide discussion, and by some, even ridicule, at once sprang up as the result of such broad and entirely new assertions which classified as end results these very common diseases, hitherto unthought of in connection with alimentary toxemia. But to-day the literature on the subject shows the gradual change of belief toward Lane's arguments.

Diagnosis.—In the diagnosis of stasis a most careful history of the patient is very important. This often begins with poor digestion, increasing constipation, and general abdominal pains, commonly about the cecum or sigmoid. These pains are accompanied by no inflammatory signs and are greatly relieved by lying down. The general pigmentation of the skin and the unexplained neuralgias, myalgias, and arthritis cases must certainly be regarded as significant. Small, hard fecal balls, sometimes interrupted by diarrhea, and the appearance of an excess of indican in the urine are quite characteristic, too. A lozenge of charcoal given the patient while he is on regular diet seems to give the most reliable information in estimating the amount of delay in the passage of food. And lastly, most important of all data, is the *x*-ray picture, carefully done and properly interpreted.

Treatment.—For purposes of treatment cases of stasis may be divided into three groups, medical, surgical, and borderland.

Medical Group.—Every case is medical at first, and 90 per cent. can be either cured or helped by medical means. We must learn to make our diagnosis just as early as possible, and to realize that the treatment will vary according to the peculiari-

ties of the individual case. Of all the means at the command of the internist, I want to mention five that have proved most efficient to me. First, the use of liquid paraffin oil. This substance has no chemical action and is not absorbed in the intestinal tract. It acts as a lubricant, protecting the mucous membrane and prohibiting bacterial growth. In its use, however, we should take precautions to secure oil that has been thoroughly purified, in view of the fact that it is known that persons engaged in paraffin work are subject to cancer. These noxious substances, however, are soluble in water and may be removed by a special purifying process. Second, another helpful medicinal agent is the combination of urotropine and benzoate of soda. This chemical reaction liberates formaldehyde, which is directly destructive to the colon bacillus. Third, in a great many of the cases where putrefactive symptoms predominate, I am in the habit of using a pure culture of *Bacillus lactis bulgaricus*, and very often with marked improvement. Fourth, I would urge careful examination of the rectum and anus. Many distended colons owe their origin to an unusually tight or spastic sphincter, a dilatation of which is helpful. Fifth, a proper fitting belt may be an important aid. There are hundreds on the market, but most of them have their defects. They have uncomfortable perineal straps, or ill-fitting and improperly placed pads. The form of support adopted by Lane consists of a pad placed in the median line just over the symphysis, held in place by steel springs encircling both sides of the body below the crests of the ilium. This exerts a pressure upon the lower abdomen, from below upward, assisting to raise the intestines from the pelvis and to empty the accumulated feces.

Surgical Group.—These cases are the late ones which all other methods have failed to relieve. There is left but one surgical procedure, namely, some short-circuit operation. Lane cuts off the ileum about two inches from the ileocecal valve and joins it to the sigmoid. He renders the entire colon useless, and in some cases removes it. Mayo joins the end of the ileum to the side of the transverse colon, leaving the greater portion of it with its omentum, which prevents most of the adhesions. He removes merely the cecocolon. Both operations seem radical and have been severely criticized, yet surgeons are everywhere reporting successful results.

Borderline Cases.—The cases in this group are surgical, too, for some interference is necessary. Just how much repairing can be done with impunity is still a question. Our primary efforts must be to relieve constrictions, with as little plastic work as possible, and the treatment must be decided upon after the abdomen has been opened. I believe certain general rules should guide us. Always explore the terminal ileum, the competency of the ileocecal valve, the appendix, and the cecocolon. Constricting bands should be cut transversely near their parietal attachments, and sutured longitudinally. Cover in all denuded edges. That characteristic thin membranous veil, spreading out to enwrap the colon, need not be removed in toto, merely ligate any cord-like fibers. If gentle, firm pressure upon the ascending colon and cecum causes the previously empty ileum to become distended, then the ileocecal valve is incompetent. Dr. Kellogg suggests a bit of repair work for this condition. He says: Rotate the colon outward, and it will be seen that normally there is a narrow muscular band passing just behind the ileocolic junction. This is called the haenula and serves to pucker and invaginate the gut. It is this band that is usually ruptured when the valve is incompetent. Now insert a suture through the seromuscular coats of the colon and ileum at such points as will cause a slight invagination of the ileum, and then place another suture through the separated ends of the haenula. This simple procedure repairs the valve.

The surgical procedure, appendicostomy, is very often advantageous and should not be forgotten, especially in those cases where the appendix is normal and where we have freed the intestines from many adhesions. The colon here has lost its proper function for so long a period that daily irrigations through this opening keep it free from fecal accumulations and greatly assist in its early restoration.

For the treatment of severe grades of ptosis, several reefing methods are suggested, rather than stitching fast organs that are normally movable.

These plans are but an outline of what is being attempted toward benefiting such sufferers.

I have reviewed carefully a good part of the current medical literature, and I believe these few words represent the trend toward which the subject has progressed. It is surely one of the great big subjects before the medical profession to-day. Its chain of symptoms and consequent sequelæ may vary in severity with different patients, yet they form one clear clinical entity. Certainly the stage of recognition has passed, nor do we any longer doubt the existence of these characteristic ileopelvic bands, or the colonic veils, or the incompetent ileocecal valve, or a ptosis of the colon. The question of stasis to-day is the problem of eliminating waste from the body. Our future work must be to explain the actual toxic substances, their composition, their properties, the nature of immunity, and lastly, to find the best means of help for these sufferers.

TWILIGHT SLEEP IN PRACTICE.*

By W. H. W. KNIPE, M.D.,

NEW YORK.

THE wonderful results obtained by Krönig and Gauss in Freiburg by the use of dämmerschlaf, or twilight sleep, in obstetrics, have led many men to attempt the same results by the use of scopolamine and morphine. These attempts were frequently unsuccessful and in some hands the results were so bad for the mother and especially for the child, that these authorities were led to condemn the method without reserve. The bad results were due to (1) a poor preparation of scopolamine, (2) to the use of too much morphine, (3) to the attempt to achieve absolute painlessness in childbirth, (4) to a technique which was entirely different from that used and recommended by Gauss.

Other authorities in Europe have reported excellent results, where they have carried out to the strictest detail the method advised by Gauss, and where they have used preparations that were stable. In this country, several years ago, scopolamine and morphine were used in obstetrics to a considerable extent, but the results were so bad that the method was cast aside by all obstetricians. It is needless for me to add that the method then used by us was wrong, and that our preparations were not stable.

*Read before the Section in Obstetrics of the New York Academy of Medicine, October 27, 1914.

and that we made too free use of morphine and gave entirely too large doses of scopolamine.

At the present time there will be many men who will attempt to give the twilight sleep without following the Gauss method, and, perhaps, without using proper preparations of the drug; and we may look forward to some bad reports on that account. It is essential for those of us who are using the Gauss method in this country to follow it out in every detail, and to be sure that our preparations are stable. At Freiburg and elsewhere in Germany, by men who have been trained in Freiburg, there have been reported 8,000 cases of twilight sleep with very excellent results, both for the mother and for the child; and it would seem that with similar technique and care, equally good results may be obtained by those who follow the Gauss method.

Conditions Necessary for Success.—1. In the first place, the physician should have a thorough knowledge of obstetrical forces and conditions so that he may know when interference is indicated.

2. After the first injection is given he must give all his time to that patient until the child is delivered. This, of course, is impossible in a general practice unless a man is willing to sacrifice his general work for his obstetrical case.

3. A proper preparation of scopolamine must be used which will not decompose; and morphine, or one of the morphine derivatives, must be used with extreme caution.

4. The environment must be such that a reasonable quiet and the absence of bright light are obtainable. The ideal place for the conduction of twilight sleep, therefore, is a hospital. Gauss and Kroenig have laid so much stress on this that they have never delivered a patient in twilight sleep outside of the Frauenklinic.

Technique.—After the first injection of scopolamine and morphine, the patient must be watched and her reaction to the pupillary, the motorcoordination, memory, and Babinsky tests noted. Gauss lays great stress upon the memory tests, and maintains that a twilight sleep cannot be properly conducted and the proper doses given unless the memory tests are properly carried out. Soon after the first injection the patient will show some drowsiness and will sleep between the pains, though awake during the pains. There is considerable dryness of the throat and mouth; there is extreme thirst at times, frequently marked flushing of the face, sometimes irregular movements of the hands, and at other times there is motor-restlessness of a more or less degree.

One must strive to get along with the least possible dose of morphine, and by freeing the patient from any external excitement or stimulation, one is able to keep the dosage of scopolamine down to a very low figure. The idea in twilight sleep is to keep the patient neither in a zone in which impressions are perceived and stored in the memory and in which the patient is awake, nor in that zone in which impressions are not perceived, are not stored in the memory and the patient is therefore in a state of narcosis, but in that intermediate zone between these two, where perception is present but in which there is no memory of events occurring at this time. In this correct twilight zone the patient gives evidence of painful sensations and may even cry out with the pain, demanding help. But after the ordeal is over, if the method has been properly carried out, the patient has no memory of these pains nor of the birth of the child. Gauss maintains that a condition of absolute painlessness in twilight sleep during childbirth is an admission of overdosing and brings with it those direful results which have caused so many men to discard the method.

Dosage.—The first dose consists of morphine hydrochloride, 0.01, injected subcutaneously with a record syringe; and while the needle is still in place a second syringe containing .0003-0.00045 scopolamine hydrobromide solution is inserted and injected. This first dose of morphine is never to be repeated, except under the most extraordinary conditions. In half, or three-quarters of an hour after this first injection some object in the room is shown to the patient to test her memory. This same object is again shown in 20 to 40 minutes, and if the patient remembers the object—which is generally the case—a second injection of 0.00015, 0.0003, or 0.00045 scopolamine is used, according to the reaction of the patient. If at this first test the memory is absent the second dose is withheld until further tests show return of memory. The third and succeeding injections follow according to the tests, using 0.00015 or more of scopolamine as necessary. The essential point in the proper induction of twilight sleep is a gradual scopolamine technique, beginning with small doses and reaching the twilight zone slowly. It requires from one and one-half to two hours for this twilight zone to be reached, and if one has not that time at his disposal it is better not to attempt to achieve amnesia but to seek only a diminution in the amount of pain.

Different people show different reaction to scopolamine and, therefore, the working time of a definite dose of the drug varies. After the twilight zone is reached one may frequently carry a patient along with 0.00015 scopolamine for a period of one or two hours; and the insight with which one determines, from the memory tests, the amount of drug necessary to maintain the twilight sleep, is the art of twilight sleep. By the use of the memory tests one may give new small doses of scopolamine for a long time without any cumulative effect. However, there may be certain periods of the labor, or certain events during the labor, which may have made an impression upon the patient's memory, or the patient may think that she has felt the entire labor, when, as a matter of fact, she has slept most of the time.

The failures in twilight sleep, Gauss maintains, are due to: (1) Attempts to force the condition in a short time. (2) Beginning the injection too early in labor. (3) Attempts to achieve absolute painlessness. (4) The use of too much morphine and too large doses of scopolamine.

Instead of morphine one may use narcotine morphine meconate, or pantopon, although Gauss still uses morphine in all his private cases—and my own experience leads me to do likewise.

They are testing a method of routine injections at Freiburg at the present time, the object being to simplify the technique and to do away with the memory tests. This method was published by Siegel and consists of: First Dose.—Narcophine, 0.03; scopolamine, 0.00045; wait 45 minutes then give second dose, scopolamine, 0.00045; wait 45 minutes and give third dose, narcophine, 0.015; scopolamine, 0.00015. The succeeding doses are given every hour and a half, and consist of: Scopolamine, 0.00015, and with every third dose: narcophine, 0.015. So that narcophine would be given at the third, sixth, ninth dose, etc., in addition to the scopolamine. This is the method that most men who

have visited Freiburg during this last summer have seen tested and which they assume is the Freiburg treatment, when, as a matter of fact, it is simply being tested upon the fourth class patients and is not used on the private cases. This routine method gives fair results as far as the mother is concerned; but there is a large percentage of children who are born with oligopnea and apnea; and while in a hospital with proper attention these babies all are made to breathe, in many cases it requires considerable stimulation, artificial respiration, hot and cold baths, intratracheal catheterization to bring them around. So that one could not conscientiously recommend this routine method for general use. While many children with oligopnea will spontaneously breathe and cry if left alone, those in the deeper varieties require resuscitation. This condition is probably due in this method to the repeated injections of the narcophine. We must also realize that any drug as powerful as scopolamine cannot be used in the routine method when we are dealing with subjects of varying susceptibility.

*Drugs Used.**—Scopolamine hydrobromide is put up in ampoules with mannit, so that 1 c.c. of the solution will equal 0.0003 scopolamine, and if prepared in this way the scopolamine is stable and does not decompose. Morphine hydrochloride is put up for hypodermic injection in the usual way, so that 1 c.c. of the solution will equal 0.01 morphine hydrochloride. If pantopon is used 1 c.c. equals one-third of a grain; of narcophine, 1 c.c. equals ½ grain (0.03).

There are certain disadvantages in the conduction of twilight sleep, because it requires the constant presence of a nurse skilled in this treatment, or better, the constant attendance of the physician who must give all of his time to the patient. It is not easy to carry it out—it requires experience in the method and considerable obstetrical knowledge, because the patient's outcries do not force interference where it may be indicated. The average physician is accustomed to giving very much larger doses of morphine and may find it difficult to diminish his dose. The physician may find it difficult to secure a stable solution of the scopolamine and if an unstable one is used very bad results may ensue.

Again, attention must be paid to many details, such as darkening the room, preserving quiet, stopping the ears, covering the eyes, and so forth, that may be difficult to accomplish in many places. The induction of twilight sleep requires not only a technical knowledge of the method for using scopolamine and morphine, but also good obstetrical judgment based on an adequate understanding of obstetrical forces and conditions; and the method is, therefore, best used by the obstetrician.

If the drugs have been improperly used, there is considerable danger from the direct effect upon the child itself, and the effect of the drug upon the period of labor, prolonging the length of labor to such an extent that the child's life is in danger. A moderate overdosing with scopolamine or morphine is very apt to give a condition of oligopnea or apnea. While these conditions may not be serious in the hands of experts, they may prove fatal unless proper measures are instituted.

That deep asphyxia of the child may ensue after an unwarranted dose of scopolamine or too large a dose of morphine has been demonstrated.

*Stable scopolamine solution has been made by Mr. Yaeger, chemist at Gouverneur Hospital, and used in the hospital cases. Mr. Otto Boeddiker, apothecary, 6th Ave. and 54th St., has made a stable solution, according to my directions, which is satisfactory.

All of this would seem to argue for care in the administration of the drugs. When scopolamine and morphine have been used carefully, and where the doses have been gauged according to the patient's susceptibility to the drug the child should be born crying lustily.

Twilight sleep undeniably demands more care, more thought, and more knowledge than a normally conducted labor. This increased attention paid to childbirth must result in better obstetrics by the general practitioner. This in turn will increase the respect of the public for obstetrical care and obstetrics in general will be held in higher esteem by physicians themselves. As a result of all this there will be fewer stillborn children, fewer mothers sacrificed, and the number of invalids following neglected labor will diminish markedly.

Inasmuch as most obstetrical cases must be attended by the general practitioner—and then frequently in communities where no hospital exists—it will become necessary to establish local hospitals where the physician may send his patient to have the twilight method administered by a nurse or physician trained in this method. When the time of delivery approaches the physician may be notified so that he may deliver the child in the hospital. This seems to me the practical solution of the problem of how the large mass of the population are to receive the benefit of twilight sleep, for, of course, it becomes impossible for a man with an active general practice to give the uninterrupted attention to his obstetric cases that the twilight method demands; and unless continued observation of the patient in twilight sleep is carried out by some one accustomed to the technique it is better not to attempt the method at all.

That there are certain dangers to an improperly conducted twilight sleep is admitted by all; that there are wonderful advantages in a properly conducted twilight sleep must be admitted by those who will take the trouble to investigate this matter. To attain the same good results that they have in Freiburg it is only necessary for us to follow their method and to give sufficient thought and study to the method to master it.

"BACK TO THE SOIL."

THE RELATION OF PULMONARY TUBERCULOSIS TO SOIL FORMATION.

By JOHN NORTH, A.M., M.D.,

TOLEDO, OHIO.

Why does not every person have pulmonary tuberculosis? The tubercle bacillus is everywhere. We are all exposed to the direct cause. We cannot have tuberculosis without the bacillus of tuberculosis, but this cannot grow and develop unless there is a proper soil for its growth. Some persons seem immune to tuberculosis. Why some persons are immune and others not, has been a subject for dispute among medical men.

Over forty years ago my attention was drawn to calcium and its use in the treatment of tuberculosis after reading Begdie, Coghill, Bell, and others on the use of calcium in tuberculosis. I have devoted a great deal of time in endeavoring to find out why all persons are not tuberculous. I have come to the conclusion that one of the most prominent causes is "lime starvation," as Russell calls it. Calcium is indispensable and essential in both plant and animal life. Every tissue in the body contains

its normal proportion of calcium. If from any cause the calcium becomes deficient, animals become more susceptible to tuberculosis. In all cases of incipient tuberculosis there is a deficiency of calcium and the elimination of calcium salts from the body is increased. Croftan (*New York Medical Journal*, June 12, 1909) has been experimenting with calcium in tuberculosis with animals, and finds an increased excretion of lime salts in tuberculosis. A. Robin states that while normal blood contains 8.39 to 9.109 per thousand parts of inorganic matters, principally lime salts, the blood in "pre-tuberculosis" and in the early stages of tuberculosis contains only from 6.38 to 7.85 per thousand. The elimination of inorganic matter is also excessive in pulmonary tuberculosis. Analysis of the organs of five consumptives and two healthy persons succumbing to accidents showed that the proportion of inorganic matters in the lungs of the healthy averages 12.04, while in the tuberculous lungs it averages only 7.9 parts per thousand. The contrast was still greater in the analysis of the bones in both cases. I could cite a number of such reports to substantiate the importance of calcium in tuberculosis, but this is sufficient at the present time.

The calcium found in the system comes originally from the soil. I have been endeavoring for a number of years to collect evidence to prove whether there is any relation between the prevalence of pulmonary tuberculosis and soil formation. I find that there is a direct relation between pulmonary tuberculosis and "humid and arid" soils.

Professor Hilgard of the University of California, in his work on "Soils," divides them into humid and arid soils. The following table from his work gives the average analysis of a large number of soils in different parts of the world:

	Average of Soils	
	Humid, 466	Arid, 313
Insoluble matter	84.013	70.565
Soda	.091	.264
Soluble silica	4.212	7.266
Lime	.108	1.362
Potash	.216	.729
Magnesia	.225	1.411
Br. oxid manganese	.133	.059
Peroxide of iron	3.131	5.752
Alumina	4.296	7.888
Phosphoric acid	.113	.117
Sulphuric acid	.052	.041
Carbonic acid		1.316
Water and organic matter	3.644	4.945
Total	100.178	99.993

By examining the above table we find that there is not much difference between humid and arid soils, except in the amount of calcium that they contain, estimated as oxide of calcium. The average of oxide of calcium in humid soils is .108 per cent., some soils containing even less, while in arid soils the average of oxide of calcium is 1.362 per cent. In some parts of New Mexico the percentage of oxide of calcium runs as high as 4.97, showing a great range of the amount of calcium in various soils. In speaking of humid and arid soils, I shall refer to the average amount of oxide of calcium in the soil without reference to the other ingredients making up the soil, as the object of this paper is to show the relation of calcium soils to the prevalence of pulmonary tuberculosis.

From the survey and analysis made in the United States, the following States are classified among the humid soil regions: Rhode Island, North and South Carolina, Georgia, Florida, Alabama, Mississippi, Louisiana, Arkansas, Kentucky, and Ohio. The average of oxide of calcium in these States is only about .27 per cent. All of these States show a high mortality from tuberculosis. Arkansas and Kentucky show the lowest proportion of calcium, .08. Ohio, the largest, with .28 parts per hundred. The following States are classified as belonging to arid soil regions: Montana, Idaho, Wyoming, Colorado, Utah, Arizona, Nevada, New Mexico, and California. These States show an average of 1.43 parts of calcium oxide per hundred, the highest being Arizona, which shows 2.37 parts. A number of States that are not classified as either humid or arid, have arid regions or show a large proportion of calcium in their soils. The arid soil States mentioned above are recommended as states with good climates to send tuberculous patients. I am satisfied that the soil formation has more to do with these States than climate or altitude. Some States are not put in either the humid or arid lists, have regions with a higher percentage of calcium. These regions are noted for their successful treatment of tuberculosis, as, for instance, Asheville, the Blue Grass region of Kentucky, the Adirondacks and a number of other places.

The death rate in some of the arid States, as given in the vital statistics of the census bureau, is much higher than in some of the humid States. This high death rate is among the residents of other States who have been sent to these regions and have died. The death rate from tuberculosis among the native residents is very low. Exact statistics on these matters are difficult to procure.

Certain regions have limestone substrata, with limestone outputs, and yet the soil is deficient in calcium salts and have a decided humid soil, such as we have in northwestern Ohio.

The soil of the Philippine Islands is humid, containing a small amount of calcium. A. G. Sison, in the Bulletin of the Manila Medical Society (September, 1910) says that tuberculosis is very prevalent in the Philippine Islands. Over one-third of the patients who apply for treatment in the dispensary are suffering from tuberculosis. Isaac W. Brewer (*Journal of the Outdoor Life*, September, 1910) states that the death rate in the Philippines, outside of Manila, was 210 per thousand as aginst 172 in the registered area of the United States, and that in Manila alone there was a death rate of 486 per hundred thousand as against 89 in the city of St. Paul, Minn. Emil Krulish of the Public Health Service of Alaska, in his report under date of January 22, 1913, says that tuberculosis is present in all forms, especially in the pulmonary and glandular types. Krulish places the degree of tubercular infection among the native population at 15 per cent. The valleys and low lands of Alaska have very humid soils. Japan is another with a highly humid soil. "Kitasato contributes an article on this subject to the *Zeitschrift für Hygiene*, lxiii, 1909. The conditions in Japan are peculiarly interesting as there are comparatively no cattle in Japan and consequently human tuberculosis is entirely independent of the bovine type. He examined the sputum of 152 consumptives continuously to detect the possible presence of bacilli of the bovine type but always with negative results, the human bacilli being found constantly in pure cultures. Statistics show that the disease is becoming more prevalent in Japan. Ireland is still another country that is in

the humid region and it is well known that tuberculosis is very prevalent in Ireland. A great many other instances might be mentioned showing that tuberculosis is more frequent in humid than in arid regions.

As I mentioned before, all the lime needed in the normal tissues comes from the soil. So we will have to go "back to the soil" to get it. How can this be done? A great many do not take the proper food or do not eat food containing enough lime. The modern methods of preparing, preserving, and cooking foods eliminate the lime or convert it into forms in which it cannot be utilized in the system. As a result we have lime starvation. In such cases we must resort to lime medication. Some writers advise persons in good health to take calcium in some form every day to keep up the normal equivalent of calcium.

Is there any benefit to be gained by our knowledge of the relationship of tuberculosis and soil formation? People living in arid regions have more lime in the system than those who live in humid regions. There is less tuberculosis among the people living in arid regions. Plants and vegetables grown in arid regions have more lime in their composition than those from humid soils. In arid regions the air contains more dust which is loaded with lime and as a result the inhabitants inhale lime dust, which has proven to be beneficial. A practical application would do much in the fight against the "white plague." I most heartily approve of every effort that has been made to combat the latter. But it has seemed to me that there is a missing link in the chain constituting the immunity and prevention of pulmonary tuberculosis.

Is calcium that link? Shall we go "back to the soil?"

A NEW COMBINED HEAD-MIRROR AND FACE-PROTECTOR.

By MAX UNGER, M.D.,

NEW YORK.

I BEG to submit to the medical profession a new appliance for use as a reflector and face-protector when working about the nose and throat.

This reflector is made of a watch glass, 9 inches in diameter and silvered on the convex side. A strip ¾ inch by 4 inches is left unsilvered at the level of the eyes, to look through. The mirror is set in a light metal frame, which is attached to a headband by a regulation universal joint.

The focal distance is about 9 inches. The mirror is large enough to cover the face, while the large reflecting surface insures a very brilliant light. The weight is about 225 grams and can be easily worn with an ordinary headband. The long strip of clear glass enables the physician to use either eye or both, as he wishes. This does away with the eye strain attendant on the constant use of one eye, as is required by the usual head mirror. This is especially important in throat work, in which a one-eye focus is unnecessary.

The protective property of this reflector is appreciated when one wishes to examine the nose and throat in a case of diphtheria, syphilis, tuberculosis, or other infectious disease. A further advantage is the fact that it does not give offense to sensitive patients, as an obviously protective addition to an ordinary head-mirror may do. I have found this mirror especially satisfactory when operating for the removal of tonsils and adenoids or for opening a peritonsillar abscess, as it catches

the blood and pus which is ordinarily coughed, in large quantities, into the physician's face.

1045 Fox Street

Medicolegal Notes.

Foundation for Opinion Evidence.—A physician testified that he partly founded his diagnosis that the plaintiff in an action for personal injuries had a fracture at the base of the brain on a history of the case told him by some one else, the admitting of the evidence over objection was not substantial error, since the physician saw the plaintiff soon after he was injured, and the injuries on the face plainly told all the history, which was that he had fallen from a hand car onto his face, and there was no suggestion that the history told to the witness was incorrect, and where the whole matter could be cleared up by putting another question to the witness.—Leora vs. Minneapolis, St. P. & S. S. Marie Ry. Co., Wisconsin Supreme Court, 146 N. W. 520.

Charitable Hospital Not Liable for Servants' Negligence.—The Supreme Court of South Carolina holds that it is contrary to public policy to hold a charitable institution liable for the negligence of its servants, when it has used due care in selecting them. A hospital which was originally incorporated by several physicians and charitable bodies, but later conducted by the physicians alone under the same charter, under which no profits could be realized and all receipts were devoted to the maintenance of the institution, and which derived its revenues from gifts, bequests, and fees paid by patients, and which treated some patients entirely free, and charged others more or less, according to their circumstances, is held to be a "charitable corporation," which is not liable for its servants. A private charitable hospital is exempt from liability for its servants' negligence, the same as a public charity. In an action for injuries alleged to have been sustained by the negligence of the defendant's nurses in placing the plaintiff in a bed where there were hot bottles that burnt her severely, while she was unconscious, after undergoing a surgical operation, it was held that the fact that the plaintiff paid for her room and attendance did not render the hospital liable for the negligence of the nurses. The fact that the hospital was a training school for nurses did not destroy its charitable nature, that being a mere incident to the main purposes for which the association was chartered.—Lindler v. Columbia Hospital, South Carolina Supreme Court, 81 S. E. 512.

MEDICAL RECORD.

New York, December 5, 1914.

TRAUMATIC SHOCK AND TRAUMATIC ASTHENIA.

THE subject of surgical shock has recently acquired a new and vital interest, and the methods of its prevention along the lines laid down by Crile illustrate how well a carefully worked out theory may be applied in practice. The doctrine of anoci-association regards shock chiefly from the important viewpoint of the defensive reactions of the individual to his environment. The older writers who discerned clearly the clinical manifestations of shock placed emphasis exclusively upon these manifestations, and although they were able to delineate every essential feature of shock, they failed to supply the means for its prevention.

An important study of shock from the viewpoint of its fundamental clinical signs and its neurological aspects is contributed by R. Benon to the *Revue de Médecine*, July 10, 1914. Dupuytren was among the first to devote considerable attention to this subject, and it was he who first clearly defined the essential elements of shock as "a more or less pronounced incapacity to carry on the functions of the mind and to produce muscular movements." Benon believes that modern writers have not added any important details to the earlier picture. He defines shock as a simple traumatic asthenia of various grades, appearing after any injury, whether accidental, surgical, or obstetrical; and the result of physical pain, emotional stress, or cerebral commotion. Three types are distinguished: the average, the mild, and the severe, the last being synonymous with the cases of posttraumatic stupor of the alienists. In the average case the two features that stand out are the amyosthenia and the so-called anideation. The former is characterized by the more or less complete suppression of muscular movements; the latter, by the inhibition of psychic activity. These phenomena may exhibit many grades of intensity and may be accompanied by accessory manifestations such as bradycardia, slowing of respiration, etc. In the mild cases there may be no or only a transient loss of consciousness, but the cerebral and muscular asthenia is clean-cut. The severe cases of shock are characterized chiefly by the profound mental stupor that follows the initial symptoms of physical shock, a stupor that is not always preceded by a loss of consciousness. The amyosthenia and anideation attain a marked degree of intensity. The patient is incapable of every movement and betrays complete mental prostration. This stupor may last for only a few minutes or for several days. The condition usually terminates in recovery, though complications may persist for some time.

From the neurological viewpoint the question of the diagnosis of traumatic shock is an important one. There may be some difficulty in differentiating this condition from simple amnesia or from ordinary posttraumatic mental confusion. In the former the anideation is different: the patient, although amnesic, has no difficulty in getting his thoughts together. In mental confusion the troubles in perception and cognition are quite distinct from the general mental asthenia of traumatic shock. Another condition that must be differentiated is traumatic aphasia in which there is neither muscular nor ideational weakness. There are certain medicolegal aspects of traumatic shock that should not be overlooked. Immediate or remote complications, mild or severe, may arise. The following sequelæ, though rare, acquire from this fact alone an added importance: prolonged and curable traumatic asthenia, chronic traumatic asthenia, traumatic asthenomania, and periodic asthenia.

THE MOTOR IN WAR.

MOTOR traction has to a large extent revolutionized the conduct of war. This statement refers not only to war regarded from the offensive and defensive standpoints, but with regard to the treatment and care of the wounded. Indeed the proper treatment of those wounded in the present war depends almost wholly upon the provision of an adequate supply of motor ambulances. In France, for instance, at the present time or at any rate in that part of France lying between the border of Belgium and Paris and over which armies have been advancing and retreating, bridges have been destroyed and railway facilities so disorganized that it is impossible to convey the wounded by rail to Paris. Furthermore, owing to the long range of modern artillery, field hospitals have to be placed at least twelve miles in the rear of armies. It is obvious that the more quickly wounds are treated the better will be the chances of good results or of ultimate recovery. This is especially the case with wounds infected by soil and which if not cleaned promptly and subjected to treatment by antitetanic serum will eventuate in lockjaw. As a matter of fact, tetanus has been most disastrously rife among the troops of both the allied armies and the Germans, because it has not been possible to treat soil-infected wounds at once and in the manner best calculated to prevent the germ of tetanus from gaining a foothold.

In a paper contributed to the *Military Surgeon* for November, 1914, Capt. F. W. Foxworthy, Medical Reserve Corps, U. S. A., emphasizes the need of motor ambulances for war purposes and says that acting on a suggestion from the British War Office the committee in charge of the American Women's War Relief Fund has dropped the idea for the time being of equipping and maintaining a hospital ship and has instead presented the medical corps with six

motor ambulances for use at the front. Captain Foxworthy draws attention to the fact that American surgeons in Paris start early in the morning with a large number of motor cars and go to the battle scene forty or fifty miles away, pick up the wounded, and carry them back to base hospitals near Paris. He also states that the German army has motor hospitals.

In the *Glasgow Medical Journal* for November, 1914, the need of ambulance wagons for the British mobile field hospital is referred to and Sir G. T. Beatson is quoted as saying that increase of impedimenta in modern warfare has made the transport question one of the chief problems of the present campaign. For the general supply of food, ammunition, medical stores, etc., to an army there are three zones of operation. The first starts from the reserve depot and base of supply and goes up to the railroad; from there another zone extends to what is called the "refilling zone," and then there is the zone of the fighting line. In each of these zones a different vehicle of transport has to be employed. With regard to medical assistance to the wounded, owing to the destruction of railways and bridges the only way to bring the wounded from the cleaning hospital to Paris as quickly as possible is by motor ambulances. Sir Alfred Keogh, head of the British Medical Service, has stated recently that what is wanted is money for the purchase of motor ambulances; and indeed opinion seems to be unanimous that motor transportation is essential to the success of an army in the field and that it is of no less value in the treatment of the wounded. This is one of the great lessons already learned from the present war.

"WAR MEDICINE EVENINGS" IN GERMANY.

THROUGHOUT the German medical centers the established local medical societies hold sessions known as War Medicine Evenings. Each of these memberships comes into first hand contact with the wounded and is well able to discuss the problems of first aid dressings, transportation, sanitary personnel, and the like. The frequency with which local meetings are held varies with the city.

In the *Deutsche medizinische Wochenschrift* for October 12 are reported the proceedings of two such meetings held at Heidelberg on September 15 and 30 by the Naturhistorisch-medizinischer Verein. A subject freely discussed was the room for improvement in transportation of the wounded. At its worst this consists in moving the troops in freight cars covered with straw sacks and mattresses. There are no arrangements for lighting and heating and no conveniences for the reception of excreta, although diarrhea is very common. There are no stopover arrangements such as would greatly facilitate renewal of dressings. The bedding becomes saturated with discharges. Trains proceed slowly, stops are frequent, there is no proper classification of wounded, and there is a marked shortage in the number of surgeons and attendants.

No single subject receives so much attention as tetanus. While figures are seldom given there is reason to believe that the disease is very frequent and very fatal. Völker stated that antitoxin gives the best results by the subdural method. He appears to favor especially the therapeutic method of Baccelli. Rost said that fragments of shell in dry weather are a frequent source of tetanus. All wounds made under these conditions should be opened broadly and treated with hydrogen peroxide or potassium permanganate to kill the tetanus spores. Heddaeus praised the intraarterial method of injecting antitoxin. The internal carotid is to be exposed for this purpose. It thereby becomes possible to reach quickly and surely the tetanus toxin in the brain.

BLOOD THREADLETS.

UPON the introduction of dark field illumination into medical microscopy peculiar threadlike bodies were described as visible in the blood, in which fluid they floated with a wave-like spontaneous movement between the blood corpuscles. They were variously regarded as artefacts and parasites. Apparently a constant blood find of man and warm-blooded animals their number was much increased in certain diseases, notably acute general infections. As the numerous data concerning the incidence of these bodies in the blood have never been collected and systematized and as the subject has fallen into more or less neglect, Knack attempted to revive interest therein, in a paper read before the Biological Section of the Aerztlicher Verein of Hamburg last summer (*Münchener medizinische Wochenschrift*, October 6). He described a simple method of rendering the bodies visible, but was unable to account for their presence. The only hypothesis held at present is that they are derived from the disintegration of red blood cells, and represent a myelin form set free from the cell lipoids. He pointed out that the threadlets could not be derived from the blood fibrin.

PARALYSIS AGITANS AND THE PARATHYROIDS.

IN innumerable instances in medical practice it has been promptly shown that various alleged specifics are worthless in routine treatment. The so-called Parkinson syndrome, which comprises tremor and muscular rigidity in association with a great number of symptoms which ordinarily suggest neurasthenia, agrees in many ways with the deficiency symptoms associated with non-functioning of the parathyroids. Nevertheless not many medical men would trouble themselves to make a crucial test of so simple a problem by the administration of parathyroid substance to subjects with paralysis agitans. This is what Professor Schottmüller reported at a meeting last summer of the Biological Section of the Aerztlicher Verein of Hamburg (*Muenchener medizinische Wochenschrift*, October 13). He obtained a preparation of parathyroids and administered it to a woman patient with paralysis agitans. She was not enlightened as to the nature of the medication, although it was vaguely intimated that she should improve under its use. As a matter of fact, she became worse under the treatment and better when it was interrupted. The author was forced to conclude that the disease was maintained by the presence of the parathyroids, which he promptly extirpated. The result of the operation was absolutely negative, and the author therefore eliminates the participation of the parathyroids in the causation of paralysis agitans.

News of the Week.

Crocker Cancer Research Fund.—The first annual report of the George Crocker Special Research Fund for the investigation of the nature and cure of cancer has just been published by Columbia University, and gives a résumé of the general lines along which research has been conducted under the director, Prof. Francis C. Wood, since the opening of the new laboratory building in December, 1913. All the research work on cancer is now carried on in the Crocker Laboratory, which is a three-story and basement, fireproof structure, recently erected on East Field, at the corner of Amsterdam Avenue and One Hundred and Sixteenth street. The necessary funds were supplied by the Trustees of the University, and the building is very completely equipped for the purpose for which it was designed. The working staff consists at present of the director and five assistants, all well known by their previous investigations in pathology. The extent of the work as now conducted is shown by the fact that at least three thousand mice and rats are required each month for inoculation with experimental tumors. The report goes into some detail as to the research being conducted. One line has been a study of the action of radium and *x*-rays on tumor and normal tissues growing in culture media, and the director reports that the results so far obtained are extremely discordant, showing that great caution is necessary in drawing any conclusions, and that hasty generalizations as to the sensitiveness or lack of sensitiveness of tumor or normal tissue to these rays are not warranted. Another large series of experiments has been carried on to test the action of radium on primary tumors of mice, and the results have not shown that this agent has any great therapeutic effect on such growths, although they correspond very closely with tumors in man. In addition to the work on animals, a considerable amount of radium treatment has been given to patients in hospitals, and data are thus being collected which will permit of a much more accurate judgment as to the therapeutic effect of radium than has been possible from previously published reports. Still another phase of the work has been a study into the conditions under which it is possible to obtain immunity to the chicken sarcoma discovered by Peyton Rous of the Rockefeller Institute. Investigations on the therapeutic effect of certain collodial silver preparations, so highly vaunted, not only in this country but also in Germany, as of great value in the treatment of malignant disease, have shown that, unfortunately, such substances have no effect on cancer in either man or animals. In addition to this research work some of the members of the staff have given courses on the nature and diagnosis of human and animal tumors. The Fund has already collected a valuable library of works on cancer, and a large number of slides and specimens of tumors are being gathered and filed for reference. The director hopes that the laboratory will ultimately be able to offer to those who are interested in the subject, including both physicians and the lay public, not only the results of scientific research, but also general information concerning the diagnosis and treatment of cancer.

Health of the Canal Zone.—The report of Dr. Charles F. Mason, chief health officer for the month of September states that the total number of deaths from all causes during the month was 22. Of these, 18 died from disease, or 5.31 per thousand, as compared with 3.26 for the preceding month and 7.30 for the corresponding month of last year. The diseases causing the largest number of deaths were as follows: Organic disease of the heart, 2; pneumonia, 4, and tetanus, 2. No other disease caused more than one death. The total annual admission rate for malaria was 77.39, compared with 89.73 for last month, and the total noneffective rate, 1.43, compared with 1.95 for last month. Each of these rates was lower than for the same month last year.

A Bequest to the Rockefeller Institute.—It is announced that, litigation on behalf of relatives to prevent the probating of the will of the late Henry Rutherford having been dropped, a bequest of $200,000 to the Rockefeller Institute for Medical Science will be paid. The income from this fund is to be used for the investigation into the causes and cure of cancer.

The Roentgen Ray Association, organized by a number of *x*-ray workers, "to improve the practice and study of roentgenology and to form a closer association among roentgenologists, or *x*-ray experts," was recently incorporated in this city. The incorporators are Drs. George S. Dixon, I. Seth Hirsch, Adoniram Judson Quimby, William A. La Field, and Archibald P. Evans.

Dr. T. A. Kenefick of this city writes to correct an error in an article on "The Relief of Gas Pains after Appendicectomy" by him in the *New York Medical Journal*, abstracted in our issue of November 21. In the original article the drug used by him was said to be acetyl-salicylic acid; it should have been acetol-salicylic acid.

High Honor for a German General.—The University of Königsberg has conferred the honorary degree of M.D. upon General von Hindenburg, commander of the Germany army operating against the Russians. He should now be able to make the Russians take their medicine.

New Counsel to the County Medical Society.—George W. Whiteside, Esq., has been appointed counsel to the Medical Society of the County of New York. He was on the staff of District Attorney Jerome six years and one year on the staff of District Attorney Whitman.

Herter Lectures.—Professor Lafayette B. Mendel of Yale University will deliver this year's course of lectures under the Herter Foundation of the University and Bellevue Hospital Medical College at the Carnegie Laboratory, 338 East Twenty-sixth Street, on December 10, 11, 14, and 15, at 4 o'clock. The lectures will be on "Aspects of the Physiology and Pathology of Growth."

Clinical Association of the Alumni of the Long Island College Hospital.—At a meeting of this society to be held Monday evening, December 7, there will be a general discussion on the "Cardiovascular System." The speakers will be Drs. J. A. McCorkle, John C. Cardwell, Joshua M. Van Cott, Luther F. Warren, and F. E. West.

Antivaccinationists Disappointed.—A boy of six years died a few days ago in Brooklyn shortly after having ben vaccinated, and his father and others claimed that death was due to tetanus caused by the vaccination. An autopsy revealed the fact that the child had died of meningitis.

Medical War News.—An American Red Cross Hospital has been established at Pau, and many wounded from Morocco are being cared for in the baccarat rooms in the casino. The Paris *Temps* says the organization of the hospital is perfect and the

surgical skill is of the best character. It gives praise to Drs. Kirby-Smith and Fayerweather, the American surgeons in charge of the hospital, and their assistants and the nurses.

A correspondent of the *New York Times* telegraphs from Northern France that one hundred Canadian doctors have come over to establish a hospital, which promises to be one of the most magnificently equipped of the many which have come from all parts of the world. The spot chosen by the Canadians is a favorite seaside resort. Their building is the clubhouse of the golf club. Many of the contingent are French Canadians from Quebec. The medical staff took possession of the building on November 26.

An American hospital, equipped with forty beds, for the treatment of wounded Russian soldiers, the gift of the American colony, was opened at Petrograd on November 28.

A staff correspondent of the *New York Times* sends from Berlin a description of a new hospital train de luxe equipped by the Red Cross Association of the Duchy of Brunswick. It is the forty-eighth train of the kind presented to the government by the Red Cross Association or individuals. It consists of thirty-eight cars. The last car is the laundry and a storeroom for linen, bedding and clothing. The next car is stocked with food supplies, and the one in front of that is the kitchen. The fourth car is the operating room and storeroom for drugs and surgical supplies. Then comes the lounge for the doctors and nurses, and in front of that two saloon cars for wounded officers, two sleeping cars for the medical and nursing staff, and twenty-nine hospital cars for wounded soldiers. In addition to these forty-eight privately equipped hospital trains there are a great many regular military hospital trains, besides trains of freight cars and ordinary passenger coaches for the slightly wounded.

The report of the American Ambulance Board in Paris shows the cost for each patient per day in the American Ambulance will be less than 10 francs ($2), as all the services of the staff of upward of 300 surgeons, nurses, orderlies, and managers are given free. There are now 350 patients in the hospital.

Mrs. Harry Payne Whitney's flying hospital of 200 beds is installed for the present in the college building at Juilly, France, not far from Compiègne. Dr. Walton Martin is chief of staff and has five assistant surgeons, Drs. Karl Connell, Donald Gordon, Henry James, and Karl M. Vogel of New York City, and W. G. Drennan of Birmingham, Ala.; there are also fifteen nurses.

It is stated in *Paper* that there is an urgent demand from the Russian Army Medical Service for bleached cellulose, which has proved an admirable substitute for surgical dressings of lint and cotton. For the manufacture of this cellulose wadding, or cellulose cotton, as it is called, special machinery is required. The material was formerly imported from Germany, but now the Russians are looking to Stockholm for a supply. Absorbent cotton is said to be not readily obtainable in Russia. Surgeons in the Swedish army prefer cellulose cotton to any other material for dressings.

Hospital News.—The corner stone of St. John's German Lutheran Hospital in St. Paul, Minn., was laid with appropriate ceremonies on Sunday, November 15.

The new Mt. Sinai Hospital, Milwaukee, was dedicated on Sunday, November 15. The hospital is a six-story building, fireproof and soundproof, erected at a cost of $160,000.

St. Francis Hospital at Cape Girardeau, Mo., under the charge of the Franciscan Sisters, was dedicated on Sunday, November 15, by Archbishop Glennon of St. Louis. The new hospital is a three-story and basement building, the erection and equipment of which cost about $200,000.

A new wing of Hamot Hospital, Erie, Penn., was dedicated by Bishop Israel on November 21. The new structure is six stories high, absolutely fireproof, and contains fifty-six rooms for private patients, besides wards and operating room.

A new hospital for contagious diseases at Haverhill, Mass., was opened for the reception of patients on November 30.

Medical Society Elections.—At the annual meeting of the Tri-State Medical Association of Tennessee, Arkansas and Mississippi, held November 18 and 19, at Memphis, the following officers were elected: *President*, Dr. W. P. Hicks of Earle, Ark.; *Vice-Presidents*, Drs. J. L. Hare of Wynne, Ark.; E. R. McLean of Cleveland, Miss., and Vernon Dickson of Covington, Tenn.; *Secretary*, Dr. J. L. Andrews of Memphis; *Treasurer*, Dr. J. A. Vaughan of Memphis.

The Eleventh District Medical Society of Georgia, at its meeting in Douglas, on November 19 and 20, elected the following officers: *President*, Dr. J. M. Smith of Valdosta; *Vice-President*, Dr. B. H. Minchew of Waycross; *Secretary-Treasurer*, Dr. J. W. Simmons of Brunswick; *Board of Counsellors*, Drs. J. T. Colvin of Jesup; E. P. Little of Manor, and A. Flemming of Waycross. The next meeting of the society will be held at St. Simons on the second Tuesday in June, 1915.

The Klamath County (Oregon) Medical Society was organized at Klamath Falls on November 14 The following officers were elected: *President*, Dr. L. L. Truax of Klamath Falls; *Vice-President*, Dr. J. L. Harris of Bonanza; *Secretary and Treasurer*, Dr. E. M. White of Klamath Falls.

At a meeting of the Northeast Texas Medical Society, held at Texarkana, November 17, the following officers were elected: *President*, Dr. C. A. Smith of Texarkana; *Vice-Presidents*, Drs. C. F. Mosely of Jefferson, and W. C. Crutcher of Mt. Vernon; *Secretary-Treasurer*, Dr. J. N. White of Texarkana.

Obituary Notes.—Dr. CHARLES WOOD MCMURTRY of New York, a graduate of the Harvard University Medical School, Boston, in 1897, instructor in dermatology in the College of Physicians and Surgeons, Columbia University, attending physician in dermatology in the Out-Patient Department, St. Luke's Hospital, and a member of the American Medical Association, the New York State and County Medical Societies, the American Association for the Advancement of Science, the New York Academy of Medicine, the Medical Society of Greater New York, and the German Dermatological Society, died at the Roosevelt Hospital on November 25, following an operation for appendicitis, aged 42 years.

Dr. WALTER C. STILLWELL died of apoplexy at Philadelphia on November 14 at the age of 63 years. He was graduated from the medical department of the University of Pennsylvania in the class of 1873.

Dr. FRANK N. YEAGER of Hamilton, Pa., died on November 14 at Rochester, Minn., as a result of an operation. He was graduated from the medical department of the University of Pennsylvania in the class of 1888. He was a member of the Jeffer-

son County Medical Society and of the Medical Society of the State of Pennsylvania and a Fellow of the American Medical Association.

Dr. WILLIAM HENRY BAKER of Boston, Mass., a graduate of the Harvard University Medical School in 1872, a member of the Massachusetts and Suffolk District Medical Societies, and organizer of the department of gynecology in the Harvard Medical School, died at his home in Waltham, Mass., on November 26, aged 69 years.

Dr. ALBERT BARNES DORMAN of Winthrop, Mass., a graduate of the College of Physicians and Surgeons, Boston, in 1892, a member of the American Medical Association, and the Massachusetts and Suffolk District Medical Societies, and for fifteen years a member and for twelve years chairman of the Board of Health of Winthrop, died at his home on November 22, aged 59 years.

Dr. JAMES SULLIVAN HOWE of Boston, a graduate of the Harvard University Medical School in 1881, visiting physician to the Boston Dispensary, professor of dermatology at the Tufts College Medical School, and a member of the American Medical Association, the Massachusetts and Suffolk District Medical Societies, the American Dermatological Association, and the Boston Dermatological Club, died at his home in Brookline on November 22, aged 56 years.

Dr. WILLIAM H. SMITH of Rushville, Ind., a graduate of the Western Reserve University Medical Department, Cleveland, O., in 1876, a member of the Indiana State Medical Association and the Rush County Medical Society, and a veteran of the Civil War, died at his home after a short illness on November 12, aged 81 years.

Dr. THOMAS W. BOTKIN of Farmland, Ind., died at his home from paralysis on November 17, aged 70 years.

Dr. A. G. HUMPHREY of Galesburg, Ill., a graduate of the New York Hygeio-Therapeutic College in 1858, died in Kansas City on November 17, aged 82 years.

Dr. WILLIAM TERRENCE CAROLIN of Lowell, Mass., a graduate of the Harvard University Medical School, Boston, in 1877, a member of the American Medical Association and the Massachusetts and Middlesex North District Medical Societies, and a former member of the Massachusetts State Board of Health, died at his home after a lingering illness on November 21, aged 64 years.

Dr. HAROLD WILLIS HARTWELL of St. Louis, Mo., a graduate of the University of Michigan, Department of Medicine and Surgery, Ann Arbor, in 1883, and of the New York Homeopathic Medical College and Hospital in 1884, died at his home on November 17, aged 56 years.

Dr. GEORGE EDWARD GAVIN of Mobile, Ala., a graduate of the Louisville Medical College in 1896, and a member of the American Medical Association, the Medical Society of the State of Alabama, the Mobile County Medical Society, and the Southern Surgical and Gynecological Association, died at his home after a long illness, on November 14, aged 43 years.

Dr. ADELBERT ALLEN BRYSON of Boston, Mass., a graduate of the Bellevue Hospital Medical College, New York, in 1892, died at his home in Dorchester on November 15, aged 54 years.

Dr. JOSEPH MORRISON TYDINGS of Louisville, Ky., a graduate of the Kentucky School of Medicine, Louisville, in 1861, died at his home on November 12 after a long illness, aged 78 years.

Obituary.

CLINTON WAGNER, M.D.

THE death, at Geneva, Switzerland, on November 25, of Dr. Clinton Wagner, late of New York City, removes a man of no ordinary note. Born in Baltimore in 1837, his family were among the earliest settlers of Maryland. He was educated at St. James College, Hagerstown, Md., and was graduated in medicine at Baltimore in 1858. The same year he entered the medical corps of the U. S. Army, passing first of nearly thirty applicants. On the breaking out of the Civil War he remained loyal to the Union and having attracted the notice of Surgeon-General Hammond was given a position of responsibility. After several promotions he became Surgeon-in-Chief of the Second Division, Fifth Army Corps, Army of the Potomac, with the rank of Lieut. Colonel. His military career was distinguished for conspicuous bravery, rare surgical skill, and marked executive ability. He established numerous field hospitals and on the Mississippi River organized the first floating hospital in western waters.

At the close of the war Dr. Wagner retired from the army and went abroad, spending two years in London, Paris, and Vienna in the study of laryngology. Returning to New York he established himself as a specialist in that department, soon becoming recognized as a teacher, as well as practitioner, of distinguished ability. He established the Metropolitan Throat Hospital and Dispensary, a model institution, rivaling the best clinics of its kind abroad, and becoming famous among those desiring advanced instruction. He showed great inventive genius, devising many new instruments and surgical methods. His general surgical experience and extraordinary skill enabled him to undertake with success important major operations upon the throat and neck. He was the best master of thyrotomy of his time and his technique of this operation has not been surpassed. In a pioneer thesis in 1882 he called attention to "Mouth Breathing in Its Relation to Medicine." His other contributions were numerous and valuable.

In 1882 he was among the first to enter upon the organization of the New York Post-Graduate Medical School and Hospital and was its first professor of laryngology and rhinology. In 1873 Dr. Wagner suggested the formation of a Society of Laryngology and, inviting to his house Drs. Lefferts, Asch, Bosworth, Woolsey Johnson, Bridge, McBurney, Weir, Mann, and Kinnicutt, organized the first society of its kind in the world—The New York Laryngological Society. Five years later, mainly through the inspiration of Dr. Wagner, the American Laryngological Association was organized. The New York society antedated by fifteen years any similar society in Europe. In 1885 it became the Section in Laryngology of the New York Academy of Medicine.

Dr. Wagner retired from practice several years ago and has since lived in Colorado, California, and of late abroad.

One year ago the fortieth anniversary of the founding of the New York society was commemorated at the Academy of Medicine with appropriate exercises, Dr. Wagner, as guest of honor, coming from Europe for the purpose of attending. His health had begun to fail and after his return became steadily worse. He leaves a widow.

D. BRYSON DELAVAN, M.D.

OUR LONDON LETTER.

(From Our Regular Correspondent.)

THE HUXLEY MEMORIAL LECTURE—TRANSMISSION OF MALARIA—MEDICAL SOCIETY—TUMORS OF CECUM AND COLON—CONVICT POSING AS DOCTOR—SURGEON SAVED FROM WRECK SPEAKS FOR RECRUITING MEETING—OBITUARY.

LONDON, November 14, 1914.

THE Huxley Lecture this year was delivered by Sir Ronald Ross, who devoted it to the discussion of the transmission of diseases in regard chiefly to malaria. He naturally began with a word about Huxley himself, who, he believed, would have been intensely delighted with the recent advances in the medicine of the tropics. Up to the middle of the last century Sir Ronald said we had only touched the "subscience" of the subject—we had distinguished, named and classified diseases and ascertained empirically the effects of many drugs; also Jenner had discovered a wonderful fact as to prevention. But the causes and the modes of transmission remained hidden. Then Pasteur, Koch, Lister, and others, created bacteriology—but the exact paths of transmission were in the dark, were thought to be scattered, leading us to a very vague prophylaxis.

The ancients thought parasites originated by spontaneous generation. In the seventeenth century Redi proved that this is not the case for certain insects and later Pallas argued that they originate *ab ovo*, that the eggs escape from one host and enter another. Then it was found they could find their way into a host of a different species associated with the one left—*e.g.* a parasite of dogs and cats develops also in the dog louse, so is not scattered broadcast over the earth to perish in multitudes but is kept alive near the cat or dog. The lecturer then traced the story of later discoveries up to that of malaria, perhaps the most important of all in relation to disease in the tropics. In India alone it is estimated that the annual mortality of malaria amounts to 1,300,000.

More than five hundred years before Christ malaria was held to be connected with stagnant water such as marshes. At the beginning of our era it was supposed the disease might be connected with insects which breed in marshes. Later it was ascribed to vapors given off by such water. The soil round these waters was next blamed—the telluric hypothesis. In 1880 Laveran found certain protozoal parasites in the blood. This view was recognized some ten years later and people rushed to the conclusion that they had an extra corporeal existence in marsh water, but they had no proofs. By 1894 careful study had been made of the parasites, some forms of which when freshly drawn from blood were found to emit flagella. Manson urged that these were flagellated spores, that when mosquitoes ingest blood containing them they get into the tissues of the insect and ripen.

Sir Ronald Ross then passed to his own researches, begun in Burma in 1889. He observed the poison was not uniformly distributed as it would be if given off in aerial form from water or land. He adopted the mosquito hypothesis as a working one and for two years fed the genera *Culex* and *Stegomyia* on patients having "crescents," thought by Murson to be the transmitting forms. Failure complete followed this plan and some others as well. He was working with the wrong species but he also noticed a dappled winged mosquito (Anopheline) in an intensely malarious quarter where he took the disease himself. He obtained eight of these insects and fed them on victims of malaria. Six of the eight insects died. On August 20, 1897, he was so fortunate as to find in the tissue of one the fourth day after it had fed on a patient, certain bodies he had not met with previously in mosquitoes. Next day the same bodies in his last insect of the eight, but larger and more definite. A little later he found them in two more mosquitoes and knew he was on the right track. The two unknown quantities of the complex equation were simultaneously found, viz., the species of mosquito which carries the malaria and the position taken by the parasite in its tissues—the wall of the intestine.

In July, 1898, he observed the spores entering into the insects' salivary glands and so the whole truth was seen. The parasites were carried from man and also to man. Like many larger ones they need two hosts for their life-cycle.

In America MacCullum and Opie had meantime shown that the bodies called spores were in reality germs. It has since been shown that the mosquitoes which carry malaria are about twenty-five in number and all belong to the anophelines. Thus only with them are we concerned as to malaria. But other species are responsible for other diseases, both in men and animals. A whole group of epidemiological diseases—the insect-borne—has thus been separated, perhaps the most important in the tropics, *e.g.* yellow fever, tick fever, plague, sleeping sickness, etc. Moreover these discoveries point to prevention, which Sir Ronald summed up in two words, "No vermin."

With him many of us fondly dreamed the fruit of these researches would be rapidly gathered, but fifteen years or more have gone by and mankind has not gained one-tenth of what it might have done had it put its heart into the business.

The Medical Society of London has held a full discussion on tumors of the cecum and colon in relation to operative treatment when Messrs. Waring, Sherren, Corner, and Carson related their extensive experience of the several operations they had been called upon to perform. Operators will find much to interest them in the reports. The several practitioners will be chiefly concerned with the insidious approach of such tumors, especially the carcinomatous and their very slow growth which was remarked upon by more than one speaker.

The president (Sir J. Bland-Sutton) testified to this slowness and said he had also seen secondary growth in bone operated on under the supposition that it was primary. Only after watching the patient for months did symptoms come on pointing to the original lesion. He had followed up cases five, seven, and nine years after operation when cancer at last showed itself. Sometimes at the operation it was not easy to distinguish cancer from actinomycosis and hyperplastic tuberculosis.

A man calling himself Harrison and said to be a convict liberated on license has been brought up again charged with posing as a doctor. On arrest he had two sets of visiting cards in his possession, one styling himself surgeon-major D.S.O., the other baronet Ch.B., M.B. He had engaged himself as an assistant to a registered practitioner who seems to have been satisfied with his statements when he found his alleged name in the register or directory. He saw patients for this practitioner, attended in-

quests and gave evidence and oath before the coroner. When a general of the name of Harrison died he told his employer he was the heir and "must look after his new estates." The secretary of the Medical Defence Union said he wrote to the prisoner's employer about him and in response the prisoner himself came to the union office personating his employer.

Fleet-Surgeon James Mowatt (retired) happened to be on the *Hermes* when she was torpedoed and was persuaded to relate the experience at a recruiting meeting. He said: "Twenty-four hours ago I was under fire; big and little guns were all firing. We were at breakfast when suddenly up went the table, the plates and crockery smashed and clattering round. We got on deck. I said to myself, 'You're a doctor; go to the sick bay.' I went and found a poor helpless fellow in bed. We got him out and he is saved. Going again on deck I saw a number of men with broken legs, etc.; attended to them and helped get them into a boat. I've been in it and can tell you what discipline does for you. Enlist now." It proved an effective appeal to join.

Mr. Charles Barrett Lockwood, F.R.C.S., consulting surgeon to St. Bartholomew's Hospital, died on the 8th inst., aged 58. He had contributed many papers to the journals and societies. Among them the development of the pericardium to the Royal, which appeared in the Philosophical Transactions for 1888. He was Hunterian Professor at the Royal College of Surgeons from 1889 to 1895, during which he lectured on "Hernia or Traumatic Infection," etc. He was Lettsomian lecturer in 1904, when he lectured on "Aseptic Surgery in Theory and Practice." His work on appendicitis reached a second edition in 1906.

Dr. H. Johnstone Levis, senior physician to the Victoria Hospital at Nice, has been killed in a motor accident near Bourges, France, at the age of 58.

Department Surgeon General Edward McKellar, M.I., died on the 27th inst. The most active part of his life was passed in India where he served through the mutiny. He was also in the two Burmese wars and received medals and clasps, serving through sixteen engagements. On retiring he went to Brighton to live. For several years he had been an invalid.

Captain R. G. Kinkhead, son of Professor Kinkhead of Belfast, was killed on the battlefield on the 31st ult.

Sir John C. Reade, who has just died at the age of 82, was the oldest honorary surgeon to the King and a surgeon-major-general, who entered the medical service of the army in 1854 and retired in 1893. He served through the campaigns of the Crimea and the Oude as well as the Indian Mutiny, being present in the chief battles and was wounded at Sebastopol. He was mentioned in a number of dispatches and held the Turkish medal with three clasps. For five years he was assistant to the Director-General of the Medical Department. In 1895 he was appointed surgeon to Queen Victoria. He was awarded the jubilee medal in 1897 and the coronation medals of 1892 and 1911. Received the distinguished service reward in 1892.

The Sugar Metabolism in Lymphatism.—H. Schirokauer found in cases of lymphatism in children a hypoglycemia and an increased tolerance to certain kinds of sugar, just as in Addison's disease and in experimental removal of the suprarenal glands. The author regards lymphatism as a type of hypofunction of the suprarenals.—*Jahrbuch für Kinderheilkunde.*

WITH THE GERMAN ARMY MEDICAL CORPS.

(From Our Regular Correspondent.)

WAR AND THE GERMAN PEOPLE—EAGERNESS OF MEDICAL MEN TO ENLIST—SAFEGUARDING THE INTERESTS OF THE DOCTORS AT THE FRONT—ORGANIZATION OF THE ARMY MEDICAL CORPS—ITS PERSONNEL AND EQUIPMENT—SCIENTIFIC OBSERVATIONS FROM THE SEAT OF WAR—GREAT CASUALTIES AMONG ARMY MEDICAL OFFICERS.

OBERSTDORF, BAVARIA, November 1, 1914.

WE in Germany have been such lovers of peace that when during the final days of July the diplomatic demands of Austria foreshadowed a rapidly approaching conflict, the feeling was generally one of disgust over any possible warlike developments. Then quite unexpectedly came the mobilization which aroused enthusiasm in the common people, but which among the more cultivated classes awakened rather a sense of dismay that such stupendous results should proceed from such insignificant causes. Hardly had it become unmistakably plain that the war was not a mere passing event but an unavoidable catastrophe incited by our enemies, when every man in Germany was aroused by an enthusiasm that not even the keenest imagination could have pictured. The members of the medical profession of course have been no exception in this manifestation of patriotism and devotion. In fact, so many physicians have volunteered for military service that a large proportion of them could not be accepted.

All medical students who were almost ready for their final examination were given a brief special examination and were at once ready to respond to the call of their fatherland. But the military authorities could not make use of them, for every need was otherwise satisfied. There has then arisen the necessity of conserving the economic interests of those physicians who have been drawn into the war. For this purpose the physicians who have remained behind have pledged themselves to look after the practice of their enlisted colleagues entirely without compensation. At the same time the latter have been able to draw their salaries from the insurance offices just as when they were active in the insurance service. At the physicians' guilds there have been established central offices that have looked after the interests not only of the physicians that have gone to the front, but also of their families.

A great deal of care has been devoted to the organization of the medical and nursing personnel of the army. Physicians have organized courses of study in which young women and girls have been prepared for the service of the Red Cross. Special courses have been established for the physicians who have volunteered for the war. Mention may be made of the lecture delivered by Halzhäuer upon the organization of the sanitary corps and the sanitary service in the army. As regards the personnel, the chief medical officer of the army is the chief of the general medical staff stationed at headquarters. The entire military force is subdivided into armies with an army surgeon at the head of each.

Each army is made up of a number of corps each with its own surgeon in charge, who is assisted by an advisory surgeon and an advisory sanitary expert, both of whom are generally drawn from the ranks of the university professors. Next in order come the division surgeons, the regimental

staff surgeons, the battalion surgeons, the senior surgeons, the assistant surgeons, and finally the subordinate field surgeons. In addition each army corps has three sanitary columns that march with the fighting ranks, and include two hundred bearers of wounded and an assistant surgeon, all under the command of a cavalry captain.

Every soldier is equipped with his first-aid packet, every sanitary officer with his instrument set. Every member of the sanitary corps has special packets, drinking flasks, and bandages. Each batalion has its sanitary supply wagon in which all conceivable first-aid appliances, including blankets, stretchers, etc., are available. The sanitary contingent are regularly drilled both at home and in camp. Every halting place marks a link between home and the army, both in personnel and material, new supplies and new recruits being received, and other supplies and disabled men being sent home. When the troops go into battle a place is set aside for the wounded. From this field hospital the wounded are sent to the more remotely placed ambulance stations, which are subdivided into the receiving station, the dressing station, the waiting place, kitchen, place for the dying, and the morgue.

There are differentiated three groups of wounded —those able to march, those transportable, and those not transportable. The last are distinguished by means of white pasteboard tags, each marked by two removable longitudinal red stripes. If one stripe is removed this signifies that the individual is transportable; if both stripes are removed the bearer of the tag is recognized as being fit to march. All those wounded not able to march are sent to the field hospitals, of which each army corps is provided with twelve. Each field hospital has a capacity for two hundred wounded. Lastly, there are provided places for the gathering and for the recuperation of the slightly wounded, both during and after the battle. All the base hospitals of an army corps are subjected to inspection by a directing surgeon who is assisted by a sanitary expert and by the director of a field hospital. The wounded are classified. There are accommodations for two hundred disabled soldiers, for those slightly wounded, for sick soldiers, and for convalescents. At home, in addition to the garrison hospitals, there are the reserve hospitals, the public institutions, and the private dwellings that have been fitted out for the reception of the wounded.

In the meantime observations made by surgeons at the seat of war have been published in the medical press. It was to be expected that new experiences would be recorded, inasmuch as weapons of unprecedented destructive power are now being employed. Some of these observations will be dealt with in the next letter.

It is very sad to have to report that there have fallen at the front a large number of doctors, a number whose proportionate size is greater than any recorded in previous wars. This is to be attributed partly to the greater area of destructiveness of the artillery and rifle fire, partly to the rage of soldiers of the enemy, and, above all, to the rage of civilians. For instance, a staff surgeon was shot while examining the water of a well; it was thought that he was trying to poison the well. Other surgeons have been killed by civilians while attending the wounded on the field of battle, and still others have been killed when a field hospital has been attacked.

Progress of Medical Science.

1. The Chlorophyll Test of Gastric Motility.—By F. W. White. (See MEDICAL RECORD, September 19, 1914, page 529.)

2. Nitrogen Content of Cerebrospinal Fluid.—H. M. Adler and B. H. Ragle report the results of their investigation of this subject in 110 cases. The striking feature of the findings was the high total nitrogen content of the cerebrospinal fluid in paresis. This increase coincides with the well-known increase in albumin and globulin. The unclassified dementias included several cases that showed a high total nitrogen content. Examination of the blood with reference to the content of uric acid showed that in insane patients this content varies within normal limits.

3. Radium in Cancer and Allied Conditions.—T. Ordway points out that the best, apparently curative, results from radium therapy are obtained in certain types of skin and other localized forms of cancer. In myelogenous and lymphatic leucemia the blood picture becomes almost normal, the spleen is reduced markedly in size, and certain symptoms may be relieved without toxemia resulting. In many cases of true cancer which have advanced beyond the operable stage, or those recurring after operation, improvement from radium therapy may follow not only subjectively, but in the local condition. This improvement may include the relief from discharge, hemorrhage, and pain; the cleansing or healing of ulceration; the diminution in size or disappearance of the growth. Such cases, however, are rarely cured. Even large growths sometimes disappear under the influence of radium, but metastasis or spreading of the growth to other parts is not prevented, or the patient may succumb to the rapid disintegration of the original growth. Newer methods may improve these results of radium therapy; at present its proved value is limited, but occasionally cases beyond these well recognized limits are distinctly benefited.

4. Intraabdominal Hemorrhage Complicating Normal Pregnancy.—F. G. Balch and R. M. Green conclude that intraabdominal hemorrhage complicating normal pregnancy is exceedingly rare, but apart from trauma may arise from various unusual causes. In the presence of classical signs of internal concealed bleeding during the later months of pregnancy, a diagnosis of such hemorrhage from unknown cause should unhesitatingly be made and appropriate treatment instituted. Among the possible rare causes of intraabdominal hemorrhage complicating normal hemorrhage pregnancy may be congenital angioma or varix of the uterus. The presence of such a varix may be a cause of habitual antecedent dysmenorrhea for which no other evident anatomical or physiological cause can be found and which is unaffected by treatment. In the grave exsanguination following intraabdominal hemorrhage associated with normal pregnancy, as in the commoner obstetrical complications of placenta previa, postpartum hemorrhage, and ruptured tubal pregnancy, transfusion is a life-saving procedure of proved value and should be promptly employed as soon as the source of bleeding has been checked.

1. Insanity and Divorce.—A. Gordon discusses the inadequacy of the legal provisions of various States in this country with respect to divorce in its relation to insanity. In instances in which the law considers insanity as a cause for divorce, it is so formulated that it does not cover all forms and varieties of mental disorder, and leaves therefore possibilities for contest and litigation. If divorce is to be granted on this basis, the legal provision should be so formulated that it includes not only the absolutely incurable psychoses, but also all varieties of mental deficiencies and abnormalities which from a psychiatric standpoint render marital life an impossibility. The jurist and the psychiatrist are to be intrusted with the formulation of such a law. In preparing this important project for legislation they must bear in mind the findings of the science of psychiatry. The curability and incurability of various mental disorders are pretty well established. Assuming that the approximate duration of a given psychosis cannot be ascertained for the purpose of its being included in the list of affections permitting divorce, a divorce should nevertheless be granted, for experience teaches that serious forms of insanity usually develop in individuals of a degenerative makeup. If they are considered to have recovered, for practical purposes there is no guarantee that a recurrence in one or another form will not take place. Lucid intervals in the course of mental affections are misleading and should not be taken as recoveries.

5. Intraspinous Medication.—O. Berghausen follows Sophian's method in controlling all intraspinous injections at the Cincinnati General Hospital by taking the peripheral blood pressure. Particularly in epidemic meningitis sudden variations of the peripheral blood pressure are noticeable. In the author's experience sudden respiratory changes follow only when the blood pressure has suffered a marked change, usually a drop. It is a safe rule never to withdraw the needle until the blood pressure at the close of the injection has about reached that which was registered at the outset. The gravity method is of distinct value in attaining this end, affording a ready means of withdrawing the serum and fluid. Peculiarly when serum is used intraspinously in the management of nonpurulent infections of the central nervous system, as in tetanus and syphilis, these sudden and marked changes in the peripheral blood pressure are as a rule not noticeable. Late in the course of tetanus sudden respiratory changes are commonly seen, due possibly to the selective action of the toxin. In purulent conditions, however, the process is always acute, and the increased sensitiveness to spinal manipulations is always present. In a recent case of pneumococcic infection of the meninges, the intraspinous injection of pneumolytic serum was likewise only possible through the use of the blood pressure control method. These results at any rate tend to show that care should be exercised in all intraspinous medication.

9. The Cecum in Abdominal Disorders.—J. M. Wainwright believes that it is rarely if ever justifiable to limit any operative interference to simple removal of a supposed chronic appendix, unless the other organs in the right abdomen are carefully examined and found to be normal, or unless the appendix itself shows unmistakable gross signs of disease. Such incomplete intraabdominal operations lead to many failures to give relief. When feasible, the cecum should be examined during any operation for chronic abdominal disease, especially if constipation has been a marked feature. Attention to the cecum at the time of these operations is quite as important as attention to the appendix. It will avail little to remove a normal appendix on such occasions "on general principles" if a dilated and movable cecum is left behind.

10. Renal Tuberculosis.—J. A. Gardner concludes that early diagnosis is the chief essential in the treatment of renal tuberculosis. Ureteral catheterization and careful examination of the urine for tubercle bacilli is the only method of diagnosing a unilateral infection. Early operation offers the best chance of cure. The removal of a tuberculous kidney does not constitute a cure. Hygienic aftercare is an essential to that cure. The few cases that have been reported as cured by palliative methods cannot weigh against the preponderance of evidence that when possible the tuberculous focus should be removed.

5. Cerebellar Symptoms and Cerebellar Localization.—C. K. Mills and T. H. Weisenburg state that the so-called cerebellar ataxia, now regarded as a symptom complex rather than as a pure symptom, has been clearly differentiated from the ataxia of tabetics. Luciani's astasia, asthenia, and atonia are acquiring a new interpretation. The authors' studies emphasize the fact that asynergy is the fundamental symptom of cerebellar disease. Cerebellar tremor and the new symptoms, hypermetry and adiadokokinesis, all now

recognized as important cerebellar disorders, when reduced to their symptomatic elements, are seen to be dependent in large part if not entirely on loss or disturbance in the power of performing more or less complex movements together for the accomplishment of a definite end. Luciani's asthenia, atonia, and astasia are to be regarded not so much as special manifestations of asynergy as derivatives or resultants of asynergic effort. Asthenia is due to the exhaustion which results from efforts to perform movements which cannot be properly grouped and directed. Cerebellar atonia, which is very irregular in its expression, is a relaxation dependent on the fact that tonectic stimuli from the cerebral cortex cannot rhythmically combine with unsynergized movements. Primarily, tone is a cerebral, not a cerebellar attribute. How shall one apply the known facts of cerebellar localization in neurologic diagnosis? Simply by bearing in mind that when the trunkal movements and those movements of the limbs which must act with them to preserve static and dynamic equilibrium are affected, the vermis must be involved in whole or in part. The associated involvement of one lateral lobe in the vermal lesion will be largely determined by unilateral dysmetric phenomena, the extent of the anteroposterior involvement of the inferior vermis by the preponderance of asynergy in either the lower or the upper limbs. In the authors' kinematographic studies the presence of abnormal pelvic girdle movements in one case and of abnormal shoulder girdle movements in another, these symptoms being sometimes more marked on one side than the other, seems to give the key to the localization of the lesions both as regards their anteroposterior and lateral positions.

8. Roentgenography of Larynx and Trachea.—S. Iglauer points out that satisfactory diagnoses of diseases of the larynx and trachea can usually be made by the ordinary method of examination, but observations for the most part are limited to a study of the changes in the lining mucous membrane and give no certain information concerning the changes in its underlying and adjacent structures. The *x*-ray examination gives additional information concerning the pathological changes in the underlying cartilages, which are more or less involved whenever the laryngeal mucous membrane is the seat of a chronic disease process, such as tuberculosis or syphilis. In stenosis or distortion of the lumen of the larynx or the trachea, *x*-ray examination usually reveals the seat, the nature, and the extent of the lesion. The knowledge thus gained before operative procedures are undertaken on the larynx is of great value. Roentgenography also enables one to study the effects of operation and the position of tubes, etc. Owing to the ease with which it is carried out, this method is of a special value in the examination of children or nervous patients.

10. Cholecystitis and Streptococci.—E. C. Rosenow notes that the common presence of streptococci in the wall of the infected gall-bladder and in the center of gallstones, often in pure culture, while absent from the bile, and their affinity for the gall-bladder in animals are strong evidence that streptococci are the cause of cholecystitis in man far more frequently than is believed and serves to explain the good results reported by some as following cholecystectomy in cases of myocarditis, arthritis, and other conditions.

4. Oculomotor Paralysis of Otitic Origin. F. H. Westmacott.
5. The Occurrence of Acute Emphysematous Gangrene (Malignant Edema) in Wounds Received in the War. R. H. Jocelyn Swan, I. Jones, and J. W. McNee.

1. Glycosuria.—N. Tirard states that one has learned the value of early relief of pent-up pus, of early removal of gangrenous tissues, and of the adoption of measures to prevent septic absorption. Can one not go a step further and add yet another theory of glycosuria which may knit together in a new light the results of clinical observation, of physiological experiments, and of pathological investigations? While greater influence on glycosuria is exerted by diet rather than by drugs, the remedies which have proved most efficacious, the salicylates, are those which are ordinarily credited with the power of controlling toxic processes resulting from the growth of microorganisms. From the experimental side glycosuria has been induced in dogs by injecting into the pancreas irritants which have produced pancreatitis or extensive sloughs. By the removal of sloughing tissues, as in carbuncles, in perforating ulcers, and in gangrene, one finds clinically that glycosuria is quickly reduced. To the author these observations, collectively, warrant the suggestion that some cases of glycosuria depend upon a perversion of pancreatic secretion due to toxic absorption. If this view is correct, it may lead to the employment of a vaccine to counteract the toxic influence.

3. The Incidence of Plague in Europe.—C. Strickland concludes that the black rat was responsible for the great plagues of Europe in the past. The epidemics had a summer incidence due to the increased flea prevalence at that season. When good housing became the vogue the black rat disappeared. The brown rat did not vanquish him. At the same time the brown rat increased owing to the introduction of conditions which suited him. He has not proved a factor of any importance in the epidemiology of plague, because his shyness of man takes him as far as possible from man and decreases the chances of infecting him; his shyness takes him away from the greater centers of population, where it would be easier to start an epidemic—he is essentially a country-side rat; and in the summer the fact that he is dispersed over the country-side in search of food lessens the probability of an epizootic among his species by, it is calculated, 250 times. This fact also shows that whatever danger he creates is accentuated in the winter, which proves that he was not responsible for any of the epidemics of the past, occurring as they did in summer. It also shows that the best and most useful time of the year to attack him is in the winter. Measures directed against the black rat should be the replacement of wooden by stone structures; against the brown, no access to food supplies, street paving and concrete basements; ferreting, trapping, and viruses in the winter; good houses instead of rows of "jerry-built" structures. In general the author concludes that plague has no further potential epidemic incidence in Europe, wherever the brown rat has replaced the black.

5. Insects and War: Ticks. A. E. Shipley.
6. Epidemic Poliomyelitis. A. A. Pim.

1. The Borderland of Disease.—G. Rankin believes that many physicians as a rule do not appreciate the full significance of the small disabilities which seem to be mere ripples on the surface of the placid stream of unbroken and reliable health, but as the months and

years pass on evidence accumulates and compels these physicians to recognize that they have confused the "post" with the "propter" or alternatively the "propter" with the "post," and have failed to grasp the true inner significance of the early phenomena whose real meaning cannot be mistaken when illuminated by the fuller evidence of pathological tissue change. In the pulmonary system cases occur constantly in which misinterpretation of or neglect to search for the explanation of early and often unobtrusive signs allows the enemy to gain full possession, whereas he might have been kept at bay or defeated if he had been resolutely opposed while he was still merely a borderland foe.

4. Blood Platelets in the Treatment of Disease.—L. Dimond has employed blood platelets therapeutically in three definite ways. In the first the blood platelets are isolated from a person in perfect health, the absence of specific disease being determined by means of the Wassermann test, and of tuberculosis by means of the von Pirquet reaction; the platelets so obtained are used parenterally in varying amounts according to indication, in order to reinforce the powers of the body against the different local and general diseases due to bacteria. In addition to satisfactory clinical results following the administration of blood platelets, determinations of the opsonic and phagocytic index, quantitative agglutinin tests, as well as complement deviation reactions, indicate that after each of such injections there is a very marked rise of the antibody content of the blood. The different immunity reactions applied to the platelets and their containing plasma, more especially when applied thereto after recovery from microbic disease or after preliminary vaccine injection, indicate that they contain a very large part of the different antibodies produced in response to bacterial invasion of the organism. In addition to germ-caused diseases, the exhibition of blood platelets has been found satisfactory in cases of hemoptysis, hematemesis, and renal hemorrhage. A second way in which the author has employed blood platelets therapeutically in the treatment of bacterial disease has been as follows: The specific organism is isolated from a patient and with a vaccine made therefrom a healthy friend receives several injections until the various opsonic or agglutinin reactions indicate that this person's serum has a high antibacterial content to this particular organism. The blood platelets and their plasma are then obtained and used in the treatment of the original case. A third method, used in cases in which the toxemia is not extreme, such as chronic ulcers, furunculosis, acne, and tuberculosis, has been to sensitize vaccines obtained by isolating the organism from the patient's lesions by means of the platelets and their plasma.

Berliner klinische Wochenschrift.

October 12, 1914.

Treatment of Dysentery.—According to Göppert this affection is *par excellence* the disease of troops. In peaceful times dysentery becomes a pediatric subject: so that when war breaks out a problem in pediatrics has to be transferred to adult medicine. Of late years a new class of remedies has come into consideration here, to wit, adsorbents—by no means to be confounded with absorbents. Certain drugs by reason of their great extent of superficies can fix certain poisonous substances and render them harmless. Charcoal, especially animal charcoal and in the form obtained from blood, is a substance which can fix enzymes as well as toxins, so that when given *per os* it interferes greatly with the digestive processes. Given by the rectum it possesses no advantage over ordinary bolus alba. While the tanniniferous drugs have some power over dysentery, castor oil is the best simple remedy. Opium is also useful. In fact our treatment in routine should be comprised of all the aforementioned resources. Of newer remedies uzara preparations have been recommended. Dietetic measures are all important. Patients must always begin by fasting but when this is carried too far, especially on a one-sided carbohydrate diet, recovery is much delayed, and moreover the gastric functions become disequilibrated. Coarse foods and fat are contraindicated because they show intestinal digestion. The patient must get his mineral matter from milk, cereal decoctions, whey and buttermilk, beef juice, grape juice, etc., which classes of foods also furnish sufficient protein and carbohydrate. Sugars which ferment had best be left out of the diet. The author is silent as to ipecac as a remedy for dysentery.

Care of Wounded Prisoners in Berlin.—Brettner relates the manner in which an old barracks was quickly renovated and modernized for service as a hospital for wounded prisoners. Beds, orderlies, and a medical staff were promptly on hand, and all was soon ready for the reception of 500 wounded. With great trouble an aseptic operating room was improvised, also a wholesale bathing establishment and an autopsy room. In addition there were special rooms for wound dressing and an *x*-ray room. There were no bedsteads, patients lying on sacks of straw directly upon the floor. Seventy-two stoves were required to warm the hospital, and because of old fashioned arrangements for disposal of refuse, etc., sixty cleaning women were kept busy.

First Weeks of Activity in Military Surgery.—Levy, a surgeon in charge of the hospital referred to by Brettner, describes the Russian wounded who were sent in two large detachments directly from the battlefield in East Prussia. These were a motley lot—Armenians, Tartars, and individuals with exaggerated mongolian features alongside of large, blond, blue-eyed men. All these captives had to be bathed and given clean clothing in addition to medical treatment. It was impossible for the Germans to converse with them as no provision had been made for interpreters. The most striking lesson learned thus far is the good effects of the original simple first aid dressings, coupled with a minimum of handling and interference

Case of Healed Uterovesical Fistula with Abdominal Extirpation of the Uterus.—Nagel refers to the compilation by Neugebauer of 165 cases of uterovesical fistula. Since this period various authors have added cases, the number including the Americans, Knipe and Young. No attempt is made to bring Neugebauer's statistics up to date. The author's case had been one of pregnancy in a myomatous uterus with forceps extraction of a dead child. The pelvis was not contracted. On the sixth day postpartum the urine began to escape from the vagina. The author first saw the patient about four months later and found cicatricial narrowing of the vagina. The fistula could not be inspected through the latter, but the cystoscope readily showed an opening in the bladder. A catheter passed through the fistula failed to appear in the vagina, but could be felt in the cavum uteri by the aid of a uterine sound. The uterus was the seat of a fibroid and the vagina was almost obliterated by scar tissue. The author performed an abdominal hysterectomy, not in the interest of the tumor, but because in this way alone could the fistula be done away with. The bladder was detached from the cervix and the vaginal cicatrix excised from above and the opening in the bladder sutured. The latter step of the operation failed, as the patient could not wear a retention catheter and the fistula did not completely heal. A second intervention was successful.

Insurance Medicine.

SUGGESTIONS TO MEDICAL EXAMINERS.

BY THE INSURANCE EDITOR.

THE VALUE OF DEFINITE INFORMATION.

THE officers of a life insurance company must be assured whether a policy may be issued or not, and are seldom interested in the mental processes of the medical corps through which the conclusion is reached. Theories, uncertainties and possibilities become worse than useless by interfering with a final decision. The medical department is depended upon to give quick and unhesitating opinions, but in their efforts to meet this demand, medical directors find their work too often impeded by indefinite and incomplete reports, and, as a result of vague and ambiguous phrases, an enormous amount of extra work and correspondence becomes necessary, with the inevitable delay which is apt to exasperate both the applicant and agent. A great part of this delay and irritation may be easily avoided by care and forethought on the part of the medical examiners. If the following directions are observed, the chief obstacles to a prompt and satisfactory service will be removed.

The use of the terms "fair" and "average" is strongly condemned and should not be used in describing the general appearance or value of the risk, or, in fact in any part of the medical report except in certain places specified by some of the companies writing substandard insurance. Both terms are too elastic and ambiguous to convey much significance to those reviewing the report, as the exact meaning depends upon the personal interpretation by the individual employing them. In a general way, it is suspected, when an examiner uses either the word "fair" or "average," that in his opinion the risk is not quite up to the standard and this suspicion must be cleared by thorough correspondence. The examiner has the advantage of a personal inspection of the applicant, and he should make up his mind definitely whether, judging by the physical condition, the risk is insurable or not, and this opinion should be expressed in unmistakable terms. If the examiner cannot come to a definite conclusion, a medical director who must judge the case entirely by the statements on paper, is in a poor condition to act finally.

The terms "pale" and "pallor," when employed, should be accompanied by an explanation, and the cause should be made clear. In other words, it should be made plain whether the pallor is due to anemia or some form of disease, or whether it is the result of indoor occupation and confinement, or is an inherited complexion. The term "plethoric" should be explained in the same way. A flushed, full face may be due to actual plethora, or, on the other hand, merely to out-door life. Even the so-called "apoplectic tendency," indicated by dilated capillaries and heavy features, may be the result of exposure to the elements, or may arise from an indulgence in too much food or wine.

In giving an account of the personal history, the examiner should invariably include the dates, duration, and date of last manifestation of any illness or injury. When filling in the date, examiners are often satisfied in merely mentioning the year. While there are no objections to this if the period referred to is remote, it may become important when dealing with comparatively later events. For instance, in writing a history of inflammatory rheumatism, an examiner may say that the applicant had an attack in the year 1913. A medical director going over this report in 1914 immediately becomes interested in regard to the month in which the disease occurred, as his decision may depend to a large degree upon the fact as to whether the illness occurred a few months or a year previously. Furthermore, the action may be influenced by the duration of the attack. Syphilis affords another example, as final action will depend on the date of the last manifestation of symptoms or the administration of treatment. If a company requires four years to elapse, it will not cut this period down to three and one-half years, and must, therefore, have precise dates.

Race is frequently reported as to nationality. In other words, "American" is an answer commonly given to the question, the examiner forgetting the fact that this includes whites, blacks and Indians.

The family history, especially when questionable, should prompt a cross-questioning of the applicant with the view of ascertaining whether there was any suspicion of tuberculosis, apoplexy, or insanity in members of the family who are stated to have died of acute pulmonary diseases, childbirth, dropsy, old age, tumor, nervous prostration, general breakdown, or some unknown or ill-defined cause.

No question is more perplexing than that of habits, and the examiner should do his best to elicit a definite history, as many of those who are addicted to the use of alcohol are apt to be reticent in regard to the matter or to give misleading answers. The examiner should always ascertain the greatest approximate amount used in any one day, whether the applicant indulges to an excessive degree and, if so, the frequency and duration of the excesses, and the date of the last excess.

The report of the physical examination should be expressed by the incisive answers "yes" or "no" whenever possible. Nothing is gained and trouble is apt to ensue when an examiner theorizes upon or reports some condition which, though not exactly according to rule, is not pathological in the slightest degree. A pure cardiorespiratory sound is of no importance, but there must be no uncertainty in the report when an organic murmur is detected. Likewise, a report of the occasional difference found by percussion or auscultation between the sides of normal chests will result in complications. When the examiner thinks statements of this kind are important enough to appear in his report, they must receive attention at the home office and be cleared up before a policy may be written.

It would take too large a space to discuss in detail all of the shortcomings and delinquencies seen daily in medical reports at the home offices. It may be sufficiently significant to say that about 50 per cent. of all applications reviewed pass over the desks of the approving officers one or more times, being brought up again with information which it is necessary to obtain through further correspondence before final action is possible. Sometimes these requirements may seem trivial to the examiners, but they are not imposed for the sake of giving trouble to examiners, or annoying applicants and agents, being based upon the results of the large experience which well-established companies depend.

In concluding, the examiners are advised to state all the facts likely to affect the risk, even though they have to go outside the list of questions appearing on the blank, and to give such information as they themselves would like to have were they to occupy medical directors' chairs at the home office and review the applications.

Book Reviews.

THE MEDICAL RECORD VISITING LIST OR PHYSICIAN'S DIARY FOR 1915. Newly revised. For 30, 60, or 90 patients a week. Price, $1.25 to $4.00. New York: William Wood & Company.

THIS visiting list is too well known to need description. It contains the usual ruled pages for visiting list, consultation practice, obstetrical engagements and practice, record of vaccinations, register of deaths, addresses of nurses, patients, and others, and cash account. There is also much useful matter on surgical emergencies, dosage, etc. The paper, though thin, is good and has a suitable writing surface; the book is attractively bound: and the present writer, after using this visiting list for fifteen years, feels that he can confidently recommend it to his fellow practitioners as thoroughly satisfactory.

THE PHYSICIAN'S VISITING LIST (Lindsay & Blakiston's) for 1915. Sixty-fourth year of publication. Price, $1.25 to $2.50, for 25, 50, 75, or 100 patients per week. Philadelphia: P. Blakiston's Son & Co.

IT is difficult to say anything new of a publication that comes out for the sixty-fourth time. There has been little change in this visiting list for a number of years, and there is little need of change, for its arrangement is convenient and those who have become acquainted with it through long use will naturally prefer it in its familiar form. In addition to the blank pages for patients, obstetric engagements, records of births and deaths, and cash account, there are the usual dose tables, directions for first aid, list of incompatibilities, and table for calculating the period of uterogestation.

DER SALVARSANTOD, SEINE URSACHE UND SEINE VERHÜTUNG. Intravenöse oder Intramuskulär Salvarsaninjektion? Von Dr. CARL SCHINDLER. Spezialarzt für Hautkrankheiten in Berlin. Price, 4.80 Mks. Berlin: S. Karger, 1914.

DR. Schindler is a sturdy advocate of intramuscular injections of salvarsan and resumes in this pamphlet the reasons and experience which have caused him to form this opinion. He first prepared the 40 per cent. salvarsan oil emulsion "Joha" which he has used with success in his experiments.

DER GEGENWÄRTIGE STAND DER PATHOLOGIE UND PROPHYLAXE DES DIABETES MELLITUS, sowie die Therapie des Frühstadiums. Von Priv. Doz. De K. A. HEIBERG in Kopenhagen. Price, 1.40 Mks. Halle a. S.: Carl Marhold Verlagsbuchhandlung, 1914.

HEIBERG gives an interesting résumé of the importance of diabetes in eugenics. He emphasizes the necessity of rest in bed and the advisability of poorer patients being treated in the hospitals instead of in the outpatient department. Heiberg does not advocate oatmeal cures. He gives a series of receipts for dinner dishes, and bread and emphasizes the necessity of considering diabetic treatment of life-long duration.

DIE PERSÖNLICHE PROPHYLAXE DER VENERISCHEN KRANKHEITEN. Von Dr. med. MAX MÜLLER, dirigierenden Arzt der Abteilung f. Hautkrankheiten am städtischen Krankenhause zu Metz. Price, 1.80 mks. Halle a. S.: Carl Marhold Verlagsbuchhandlung, 1914.

DR. Müller believes that gonorrhea is best avoided by injections of 10 to 20 per cent. protargol or from 5 to 10 per cent. albargin, and that a non-fatty sublimate salve is the best preventive for syphilis in the male. He agrees with Metschnikoff that every physician should consider it immoral to refrain from advising personal prophylazis as a means of combating these scourges.

DISEASES OF THE STOMACH AND THEIR RELATION TO OTHER DISEASES. By CHARLES G. STOCKTON, M.D., Professor of Medicine, Medical Department, University of Buffalo; Attending Physician, Buffalo General Hospital, etc. With five plates, twenty-two radiograms, and sixty-five illustrations in the text. New York and London: D. Appleton & Company, 1914.

THE present book on diseases of the stomach emanating from the pen of one of the best clinicians of America and one of the foremost pioneers in gastric affections will be welcomed by the medical profession. Stockton has frequently called attention to the importance of reflex irritation as the source of various forms of dyspepsia. In this connection the author says: "I am satisfied that no unprejudiced clinician who has open-mindedly studied the question is able to deny that a large number of dyspeptics are relieved by the removal of irritation, acting reflexly through nerve paths. Nervous dysharmony is undoubtedly at times responsible for dyspeptic symptoms, yet all cases of dyspepsia are not cured by the amelioration of a focus of irritation. . . . Some are more important than others; for instance, the gall-bladder, the appendix, and the eyes, and each of these are worthy of special consideration."

Concerning the expressions "vagotonia" and "sympatheticotonia," Stockton justly says that these conditions are not new and correspond to what was formerly designated as "irritative" and "depressive" neuroses.

Stockton advocates early resort to surgery in gastric cancer, although for the present the results are far from being good. He says: "Experience has made me skeptical as to the ultimate cure of gastric cancer by surgery or other means except in a few most favorable cases. Great relief or respite of the disease may be procured, but rarely permanent cure. Ultimately, unless some intercurrent affection kills the patient, he returns to the physician for medical treatment; that is to say, for relief of his suffering."

Stockton deprecates the too frequent resort to exploratory laparotomies. He expresses himself as follows: "The statement is frequently heard that all patients complaining of the stomach, who are not relieved by medical treatment in a given time (variously estimated from one to six weeks) should undergo surgical operation. This arbitrary rule is unreasonable and highly improper until surgical expertness has rendered a celiotomy devoid of objection. To expect a physician to cure a serious disease within a definite time is to be oblivious to the natural history of pathological processes. No hard and fast rule applies. The exercise of sound judgment after all the evidence is obtained is the only conscientious guide. It is a mistake to assume that a surgical exploration necessarily lays bare the whole truth: in fact, it often fails to disclose a cancer which is actually present yet inaccessible."

Stockton's book is certainly a very valuable addition to medical literature and no practitioner should fail to have it in his library.

TASCHENBUCH FÜR KRIEGSCHIRURGEN, Ratschläge und Winke für die feldärztliche Tätigkeit auf dem Marsche, während und nach der Schlacht. Von General-Oberarzt a.D., Prof. Dr. A. KÖHLER. Price, 2.50 Marks. Berlin and Vienna: Urban und Schwarzenberg, 1914.

THIS little book is written for the guidance of the practising physician suddenly called from civil life to war, who finds himself confronted with many perplexing problems of military surgery and sanitation to which in his whole professional life he had never given a thought. The author speaks with authority, as well he may, and wastes no words in argument or weighing of theories; but states directly in a few positive words just what is to be done to meet the emergency of the moment. The work is capitally done, the instructions are clear and to the point and contained in some ninety pages of a book that could be carried in the coat pocket and could be read while in the train on the way to the front.

URSACHEN UND WESEN ANGEBORENER DIATHESEN. Eine experimentelle Studie. Von Stabsarzt Dr. HANS ECKERT, Assistant der Königl. Universitäts-Kinderklinik der Charité, Privatdozent an der Universität, Berlin. Price, 3.50 Marks. Berlin: Verlag von S. Karger, 1913.

THIS brochure details the results of an experimental study carried out on dogs in order to determine the actual nature and the causes of inherited diatheses. There are three chief hypotheses that have been advanced to explain the origin of these diatheses: Virchow's conception of an inherited vulnerability of the lymphatic apparatus; Rokitansky's doctrine of the dyscrasias or faulty constitution of the vital milieu, the blood; and Heubner's theory of a functional impairment of the capacity of individual organs. To the above there has more recently been added Czerny's hypothesis of a congenital defect in body chemistry. As the result of his metabolism experiments on dogs Eckert concludes that a defect in bodily chemism can not be regarded as congenital in the sense implied by Czerny, but is rather to be attributed to a functional disturbance of the delicate mechanism that regulates the bodily metabolism.

Society Reports.

THE PRACTITIONERS' SOCIETY OF NEW YORK.

Two Hundred and Sixty-fourth Regular Meeting, Held October 9, 1914.

DR. LEWIS A. CONNER IN THE CHAIR.

Precancerous Lesions.—Dr. JAMES EWING presented this paper. (See page 951.)

Dr. C. L. GIBSON said that he had always felt that a large proportion of these cases of simple inflammation developed subsequently into carcinoma, whether as a separate disease or not. In some cases of disturbance in the breast the lumps did not bother the patient in the slightest degree for five or ten years; then perhaps they began to hurt. Unfortunately, in these cases the pain came late and the condition was not noticed until pain occurred. He believed that there was a precancerous stage in these diseases. He had been operating for some years on these breasts and had done many operations and had come to the conclusion that a great many more radical operations should be done. Often one could persuade a woman to have something done if it could be promised that she would not be badly disfigured. In these cases the apparent lesion could be taken, but he would rather amputate the breast, especially in a woman approaching carcinoma age. In the cases he had operated on none of the women had developed carcinoma.

Dr. EWING asked if he meant after these partial plastic excisions.

Dr. GIBSON said yes: he said there was one part of the question that he did not understand; that was the question of trauma. Dr. Ewing had stated that in eczematous ulcers of the leg the majority became carcinomatous. The speaker had seen thousands of cases of ulcer of the leg and had seen only one case of epithelioma occur with ulcer of the leg. The relationship between irritation and trauma was interesting. Take, for instance, the organs which underwent changes—the breasts and the uterus; they were the favorite seat of trauma and they developed carcinoma very often. Yet the anus was the seat of frequent trauma, and you seldom saw carcinoma of the anus. The large intestine had many carcinomata, but it was not a glandular organ and did not undergo changes in rotation to function. The small intestine was glandular, but you did not get carcinomata of the small intestine; you might get an occasional sarcoma, yet in functional opportunity the small intestine had as great possibilities as any organ of the body. In regard to the prostate, Dr. Gibson doubted the relationship of hypertrophy to carcinoma. The favorite age of carcinoma of the prostate was between fifty and sixty years, and cases with hypertrophy were over sixty as a rule. In regard to the pylorus, he did not understand the transformation from ulcer to carcinoma. At one side of the pylorus it was frequently seen, but not at the other side. Ulcers of the duodenum were frequent, but a change of a duodenal ulcer to carcinoma was almost unknown. He confessed the whole question seemed a very difficult one to him.

Dr. WM. H. PARK said that though this might have no bearing on the present discussion, he should judge that the trend of the argument was away from the necessity of microorganisms being a factor in the production of cancer.

Dr. J. C. ROPER asked if Dr. Ewing considered that intracanalicular adenofibromata underwent malignant changes.

Dr. EWING in answer to Dr. Roper, said they did not often do so. He thought they arose from another portion of the breast, but a very small proportion of them might become malignant. He had never seen any lesions in intracanalicular fibromata suggesting a precancerous state.

Dr. ROBINSON asked Dr. Gibson how much of the breast he took out when he operated on the case of a hard nodule in the breast of a woman, and how radical should the removal be. He said, in his experience a non-malignant lump of the breast might sometimes turn out to be malignant later on.

Dr. GIBSON, in reply to Dr. Robinson, said that that was a pretty hard question and one could not make a hard and fast statement. In the case of a young woman going to be married and caring particularly for her personal appearance he did not amputate. If the patient was very intelligent he explained to her that she would probably not be troubled for many years, but that these things never went away and that it was better to have the lesion removed at once. When she got older she ran the risk of a malignant growth. If you told the average hospital patient that a lump in the breast was nothing she would never again seek proper advice, and when she did develop carcinoma she would say that a doctor ten years ago told her it was not malignant. The American Surgical Association adopted a resolution recommending that every woman be told to seek the advice of a competent surgeon for a lump in the breast. His attitude was the greatest good of the greatest number. He did not believe that all lumps were malignant, but if we assumed that they were there would be fewer women die of cancer of the breast. He had done many partial excisions, but if he could get a woman to have the operation done he preferred a radical operation.

Dr. DANA said that Dr. Ewing had not made any mention of precancerous lesions in the central nervous system. Of course, extremely few primary cancers occurred there. Perhaps it was because these tissues were so well protected. But, so far as the matter of irritation was concerned, there were very many chronic diseases of the central nervous system, such as old hemiplegic foci and those of multiple sclerosis, but no malignant lesions ever developed on the basis of these. On the other hand, sarcomata were frequently observed as the result of irritative lesions due to trauma.

Dr. EWING said he had another chapter on pre-sarcomatous lesions.

Dr. CONNER said that the question of dealing with a single circumscribed lump in the breast was simpler than that of the slight, diffuse changes that were sometimes seen in both breasts as a result of chronic mastitis. An unmarried woman, aged forty years, came to him for advice three years ago. In a number of scattered areas throughout both breasts the breast tissue was slightly firmer and more distinct to the feel than elsewhere. There were no symptoms. In this case there was obviously nothing in the nature of a neoplasm and the patient was reassured upon this point, but was cautioned to return at once in case any change was noticed in either breast. A few weeks ago she appeared with a distinct lump in her right breast, which she admitted she had noticed for a month or two, but which had only then begun to be painful. In this case nothing short of an amputation of both breasts could have removed all possibility of future trouble, and he would like to ask Dr. Gibson if he thought so radical an operation as this should have been advised when the patient was first seen.

Dr. GIBSON said that if the woman was forty years of age a double amputation would have been the only thing to do.

Dr. EWING said his object in gathering these data together, most of which were well known, was to assist in the effort now being made to reduce the mortality from cancer. While one might indulge the hope that advanced cancer might some time be controllable, there was no certainty that we should ever see it. Although it was often extremely difficult to advise the patient properly in the presence of precancerous conditions, he had been astonished to see so many unfortunate results from failure to deal promptly with early stages of carcinoma. At the Memorial Hospital one frequently heard the story that patients received reassuring statements from physicians, but when they next came for consultation it was too late. There was no doubt that practitioners in general did not realize the importance of precancerous conditions. He also found a reluctance on the part of some pathologists to admit the significance of precancerous pictures and an inclination to make light of the confidence with which he, and many others, accepted these lesions as preliminary to the clinical appearance of cancer. He did not think that he had ever differed from Dr. Gibson in any of his views concerning the breast. Several of the cases he had studied had come from Dr. Gibson's operating table, and he thought he had taken a correct and progressive position. In the case of the prostate he believed that histories and histological studies were seldom made with sufficient care to determine the existence of chronic inflammatory changes preceding carcinoma.

Artificial Stenosis of Pylorus with Gastroenterostomy.

Dr. GIBSON said he had brought two *x*-ray plates, illustrating the question of gastric surgery. We did not always cure ulcer of the stomach by doing gastroenterostomy. It had been rightly thought that the best results were in cases accompanied by stenosis of the

pylorus. This was a fair statement, but not absolute. The case presented was a man twenty years old, who was admitted to the New York Hospital in the Spring of 1914. His early history was unimportant. For the past year the patient had suffered frequently from attacks of pain in the abdomen, made worse by taking food. The stomach contents showed blood and hyperacidity. The string tests were sometimes positive, sometimes negative. The *x*-ray picture was negative. The patient's distress disappeared under soft, solid diet and rest in bed. He came under observation again in June, with a recurrence of all his troubles. He was operated on June 13. An irregular, hard, callous ulcer was found on the posterior superior wall of the stomach, juxtapyloric. A posterior, no loop gastroenterostomy with five rows of sutures was performed with Carwardin clamps. A strip of fascia 4½ inches long was removed from the fascia lata and fastened snugly around the prepyloric portion of the stomach, proximal to the ulcer. Shortly after the pylorus was ligated the patient developed a severe hiccough, although fully anesthetized. His convalescence was smooth. He was discharged sixteen days after operation, when it was noted that the patient was taking soft, solid diet with no pain, no gastric distress. He was re-examined on October 5, 1914. He presented at that time every appearance of good health and well being. He complained occasionally of a feeling of fullness in the left side of the epigastrum. Digestion was good and he was able to eat everything. Weight, 140 pounds, a gain of fourteen pounds in three months. The analysis of gastric contents showed: Total quantity, 20 c.c.; free HCl, 50; total acidity, 90; faint bile stain (guaiac) negative. The interesting feature of this case was first the complete relief of symptoms, increase of nutrition following operation, and the demonstration (1) that a strip of fascia sewed around the prepyloric portion of the stomach is capable of healing well; (2) that it accomplished its purpose—exclusion of the pylorus; that is, preventing the stomach contents from coming in contact with the pyloric ulcer and securing the maximum benefit of rest. The *x*-ray picture showed conclusively that the exclusion was absolute, as bismuth was seen distinctly coming out of the gastroenterostomy opening, while not a vestige of it appeared from the pylorus. The operation of exclusion of the pylorus had only lately been systematically considered. It had not received so much attention in America as abroad. It was probable that the operation was not required as a routine measure, and it might be that the troubles observed in certain cases were due, not to omitting this step, but a faulty technic of gastroenterostomy, a condition which was probably commoner than generally admitted. Many methods of the exclusion of the pylorus had been proposed, the most radical being that of Eiselberg, who actually divided the prepyloric portion of the stomach, sewing up the cut ends and performing gastroenterostomy. This was too severe an operation to be generally recommended. The extreme of simplicity had been practised by Lambotte, who passed a silk purse string suture around the pylorus, tying it tightly enough to produce obstruction without necrosis. Metallic bands had been devised and used by Brewer also for this purpose. His own preference for the present would be the operation just described.

Dr. THACHER asked where Dr. Gibson got the fascia.

Dr. GIBSON said he got it from the abdominal wall. It could he obtained from the thigh, but that involved making another wound.

Arseno-Ferratose: Its Efficacy in Diseases of the Thyroid Gland.—Dr. BEVERLEY ROBINSON of New York read this paper, in which he reported good results from the use of this preparation in myxedema and cretinism.

NEW YORK ACADEMY OF MEDICINE.

SECTION ON OBSTETRICS AND GYNECOLOGY.

Stated Meeting, Held October 27, 1914.

DR. GEORGE W. KOSMAK IN THE CHAIR.

Two Cases of Broad Ligament Varicocele.—Dr. HENRY DAWSON FURNISS presented these patients. He stated that the first patient was 25 years of age and had had two children. Since the birth of her first child, in 1910, she had complained of dull, aching pain in the lower abdomen and a bearing down sensation. In addition she had pain over the left iliac crest and in the left lumbar region. These pains were made worse by walking or exertion and were relieved by rest in the recumbent position. This patient also complained of indigestion and had lost twenty-five pounds during the past four years. The woman had a poor abdominal and general musculature. The only abnormality revealed by examination was a suggestion of elastic resistance on either side that disappeared on pressure. A diagnosis of broad ligament varicocele was made. At operation the ovarian veins on both sides were found to be enlarged to the size of an adult fourth finger and stood out very prominently. Both broad ligaments were a large mass of veins. The ovarian veins on either side were doubly ligated at the pelvic brim and two ligatures were placed around the veins in the base of the broad ligament. A Gilliam operation was done to give the uterus an extra support and add another help in the prevention of passive congestion. The patient had been greatly improved since the operation, though at times she still had slight pelvic pain. The causative factor in the production of the varicocele had not been removed, namely, lack of fat and muscular development.

The second patient was 23 years of age and had been married three years. In March, 1912, she had a difficult but not an instrumental labor. She received a laceration of the perineum at this time. For the past six months she had complained of constant, dull, aching pain in the lower abdomen, which at times became sharp and cutting. All the symptoms were worse when she was working and were relieved by rest. The physical examination revealed nothing abnormal except a slight perineal relaxation and an indefinite elastic resistance in the adnexal region. Because of the history of constant pelvic discomfort, made worse by work and relieved by rest, together with the negative pelvic findings, a diagnosis of pelvic varicocele was made. At operation, with the patient in a moderate Trendelenburg position, the ovarian veins at the pelvic brim were the size of an adult forefinger; they were also much enlarged in either broad ligament. The ovarian veins on either side were doubly ligated and a Gilliam suspension operation done with the idea of lessening passive congestion in the pelvis. In addition a perineorrhaphy was done. The patient made a good recovery. The day after her operation the patient volunteered the information that for the first time in three months she was free from headache. She had been free from pelvic pain since the operation. In both of these cases the diagnosis was made before the operation, and in one it was the only reason for the operation. It was the speaker's belief that many of the patients that they saw complaining of great pelvic discomfort, made worse by exertion and relieved by rest, had pelvic varicocele, and that if this was borne in mind they would be able to diagnose most of them before operation.

Complete Removal of Adenocarcinoma of the Uterus by Exploratory Curettage. Report of Three Cases and Demonstration of Extirpated Uteri and Microphotographs of Sections from the Same.—Dr. L. J. LADINSKI presented this communication, which he prefaced by the statement that the fact that an early adenocarcinoma of the uterus could be removed completely by curettage had been established as an undoubted scientific fact in 1896 when Gessner read a paper on "The Value and Technique of Exploratory Curettage," and incidentally reported two cases. Up to the present time nineteen cases had been reported, all of which Dr. Ladinski reviewed and to which he added three of his own.

CASE I.—The first case had been cited by Dr. I. C. Rubin as an example of incipient carcinoma. Dr. Ladinski had seen this patient in consultation because of profuse uterine hemorrhage. She was 51 years of age, had had four children, and had been bleeding for a number of months. She had been curetted several times, but the hemorrhage still persisted. The uterus was large and soft and a nodule could be felt near the fundus. A preliminary curettage was done for diagnostic purposes. On examination a typical adenomalignum with early adenocarcinoma was found. The glands were enormously enlarged and increased in number and the hyperplasia was so marked that the glands lay *dos-a-dos*, very little stroma intervening. There was papillary proliferation of the epithelium within the lumena and also an actual increase in the layers of cells, which were atypical in appearance and showed mitosis. A pan-hysterectomy modified after Wertheim was done. The uterus on section showed an elongated polyp. Microscopical examination of this

polyp and of the uterine mucosa showed, however, no area of carcinoma. It was evident that all the lesion had been removed by the curette. The bleeding in this case was probably due to the submucous polyp, the incipient cancer having been grafted on the polyp.

Case II.—This patient was 47 years of age, married, but had never conceived. Two years ago the menses had ceased for a whole year. For the past year she had bled irregularly. Examination showed a uterus somewhat larger than would be expected in a woman who had never conceived and had begun the menopause. A small bleeding mucous polyp protruded from the os which on microscopical examination proved to be benign. As the bleeding continued after the removal of the polyp, curettage was advised and performed. The pathological report of the scrapings was "adenocarcinoma." The patient declined a pan-hysterectomy. She then consulted Dr. Coe who also advised a hysterectomy. A little later she consulted a third surgeon who told her that she was not suffering from cancer, and never did have cancer. Two subsequent curettages done by this surgeon showed no signs of cancer on examination by competent pathologists.

Case III.—This patient, 63 years of age, had had twelve children, and had passed the menopause ten years ago. She consulted the writer because of hemorrhages that had lasted for the past ten weeks. Vaginal examination showed the uterus large and the os patulous. There was a uterine polyp with the pedicle apparently attached close to the fundus. The polyp could not be excised because of its excessive friability, and its removal was effected piecemeal with the curette. about sixty or seventy irregular masses about the size of a hickory nut being removed. Microscopical examination of sections of various masses showed necrotic adenocarcinoma. A pan-hysterectomy was done. The extirpated uterus showed macroscopically apparently healthy endometerium. A small pedicle still attached to the posterior wall near the fundus showed on microscopical examination no traces of adenocarcinoma nor did the sections of the uterus show any traces of malignancy. In these twenty-two cases, all of which were carcinoma of the body of the uterus, the disease was removed *in toto* by the curette. Of these, nine, and possibly ten, were instances of carcinomatous degeneration of uterine polypi, and in the remainder the growth was localized in the mucosa. In four of the cases no radical operation was done and the patients remained well for from one to four years. The method of handling the slides at the Beth Israel Hospital precluded the possibility of a mistake in the slides. It was proven beyond a doubt that a carcinomatous growth could be totally removed by the curette when it was limited to a uterine polyp, or when it was confined to the mucosa. There were few such cases reported in the literature because, when a subsequent curettage did not confirm the finding of carcinoma in the first curettage, the circumstance was attributed to mistaken diagnosis. Another reason for the apparent scarcity of such cases was that exploratory curettage was not resorted to as often as it was indicated and routine microscopical examination of the curettings was not practised to the extent that it should be. This was especially true in America for it was not conceivable that of the tremendous number of patients suffering from adenocarcinoma there was not a single record of this nature in this country. When clinical symptoms pointed to cancer of the uterus and exploratory curettage confirmed the dagnosis no one would question the indication for extirpation of the uterus, and there could be no question that to extirpate the uterus, even if a subsequent curettage did not reveal carcinoma, would serve the best interests of the patient. Dr. Ladinski laid great emphasis on the fact that complete removal of an adenocarcinoma by the curette could not be regarded as an adequately radical operative measure. The mere removal of the diseased area did not effect a permanent cure. Ordinary surgical rules demanded that a carcimona be removed with as wide a field as possible from the disease, and it would be contrary to all surgical rules to leave in a uterus, the seat of carcimona, even if the curette had entirely removed the diseased portion. Dr. Ladinski considered the possibility of spontaneous cure of cancer and the question of the latent state of malignancy in these cases and presented the reports of the pathologists on the cases and the uteri removed.

Dr. Eli Moschcowitz exhibited lantern slides from the three cases which Dr. Ladinski reported. The curettings from the first case showed typical adenocarcinoma, while sections from the uterine polyp showed simple adenomyoma. The curettings from the second case showed a combination of adeno and solid carcinoma. In the third the predominate lesion was an adenocarcinoma with small alveoli mixed with areas of solid carcinoma. The sections taken from the small pedicle left within the uterus after morcellement of the polyp showed hemorrhagic infiltration of a typical non-malignant adenomyoma. In the second and third cases, smooth muscle tissue was easily demonstrable within the stroma. All three specimens revealed undoubted evidences of malignancy. That a malignant tumor of the uterus could be so completely removable by the curette that no evidence of the disease remained seemed a rather strange phenomenon at first glance, but it must be remembered that many factors came into play that rendered such a contingency possible. In the first place adenocarcinoma of the uterus was a growth of relatively slow malignancy, and again, it could probably be sooner recognized clinically than a malignant tumor in the more enclosed portions of the body. There were numerous paralellisms in clinical records between the phenomenon described by Dr. Ladinski and those occurring in other parts of the body, as for instance the cure of early cancer of the rectum and larynx by simple removal of a cancerous polyp. These specimens proved the fallacy of attempting to prognosticate the clinical malignancy of a new growth by morphological characteristics alone. Mistologically these curettings showed all the criteria of a profoundly malignant growth, yet the clinical outcome showed that the condition was eminently curable.

Dr. James Ewing said that Dr. Moschcowitz had covered the ground so well that very little remained to be said from the pathological standpoint. When such a number of cases had been reported as had been reviewed by Dr. Ladinski one could not doubt the existence of such a type of uterine carcinoma, and they were not all polypoid. One might not, perhaps, be certain of the first case, but the second and third cases furnished positive evidence that this strange phenomenon could occur. The third case was unique in his experience because of the peculiar embryonal origin of the carcinoma. Dr. Ewing emphasized that cancer could not be considered as one disease but as a group of diseases and therefore no blanket rules for treatment could be laid down. The disease was different in different organs, and, moreover, it was different in the same organs and hence blanket rules could not be employed in its treatment. There should be a thorough pathological examination in every case in order to assist in determining what method of treatment was applicable in that individual case. There were various degrees of malignancy that must be dealt with in detail and he therefore emphasized the principle that one should find out with what degree of malignancy he was dealing and apply treatment accordingly.

Dr. F. M. Jeffries said that it had been his privilege to look over this series of sections and that he agreed with the findings as Dr. Ladinski had presented them. All pathologists who had had any experience had examined specimens and pronounced them carcinoma and then failed to find any carcinoma in the removed uterus, but such instances did not usually reach publication, the quarrel being limited to the pathologist and the surgeon. Although Dr. Ladinski had shown that a cure might take place after curettage there were very few cases that should go without hysterectomy.

Dr. Howard C. Taylor said that in regard to a curettage preliminary to a hysterectomy for fibroid tumor he did not believe that this was the best course. If a supravaginal hysterectomy was done after the removal of the uterus it could be opened, and if malignancy was found the cervix could then be removed. If nothing of a malignant nature was found the cervical canal could be excised with a knife and these two procedures would exclude the possibility of a malignant condition better than a preliminary curettage. The point might be raised that if a malignant condition in the fundus of the uterus was discovered by a preliminary curettage a more radical abdominal operation for the removal of the uterus would be done than for a fibroma uteri. He preferred a simple hysterectomy without previous curettage to a more extensive one after the interior of the uterus had been curetted because of the danger of scattering cancer cells into the surrounding tissues by the curette. The report of Dr. Ladinski and the cases which he reviewed furnished ample evidence that there were some cases of carcinoma of the fundus which were cured by pre-

liminary curettage. There were, however, some sources of error which it would be well to bear in mind. Pathologists did not always agree in their diagnoses of malignancy, as was shown by a case which Dr. Taylor cited. Dr. Taylor also cited a second case in which a curettage was done and the curettings pronounced to be malignant. At a subsequent operation the uterus was removed, but no evidence of malignancy was found. This seemed to be a case in which the malignant condition was entirely removed by the preliminary curettage.

Dr. I. C. Rubin said that Dr. Taylor had touched on a feature in regard to the difficulty of diagnosis which it might be of advantage to dwell upon, namely, what constituted a malignant epithelium. In certain conditions, as in healing erosions of the cervix, an alteration of the morphological character of the epithelium had been observed. The normal layer of single, slender, cylindrical cells of the cervix glands was often replaced by two or more rows of low cylindrical and sometimes cuboidal cells. Such glands, when cut obliquely, might give a rather confusing picture, the cells appearing much more irregular. There was, however, no tendency to the formation of giant nuclei, nor of deep chromatin staining, nor of atypical mitosis. He had seen similar metaplasic epithelium invading cervical and corporal polyps, and also in the chronic inflammation associated with tuberculosis and gonorrhea. From the morphologieal viewpoint such epithelium had no significance of malignaney. It was a reparative process. Occasionally they encountered an altered epithelium in the curetted material, the aberration from the normal being more in evidence, and there might be doubt as to whether the changes in the epithelium were those of a malignant growth. The best procedure in these doubtful eases was to keep the patient under careful control and observation, and if necessary a second curettage should be done. There was a third group of cases in which it was possible to recognize small cancer foci as such because of the well-marked morphological cell aberration. There was in such epithelium a conspicuous difference in the size of the individual cells, in their shape, arrangement, and chromatin content. There was no evidence of eell borders: there was clumping of the nuclei-atypical mitosis—giant nuclei, and giant cells. When these evidences were present, whether or not there was isolation of alveoli or penetration into the depth, they were sufficient in themselevs to denote cancerous epithelium. Epithelial penetrating sprouts were not absolutely essential evidence of cancer. They did occur in the majority of advanced cancers when ulceration and hemorrhage were also present. Schottlaender had shown that in 5 per cent. of cancers the growth exhibited the exophytic tendency of propagation, that was, it grew toward the uterine cavity rather than toward the parenchyma. Such growths were more amenable to radical curettage than the type that penetrated the parenchyma early and hence caused early metastases. As a rule the growth was both exophytic and endophytic, being prominently more the one than the other. There was another type of growth, and that was the so-called "sugar-coated" variety of cancer described by Schauenstein and others. This type might involve the entire mucosa of the uterus. There was slight, if any, penetration of epithelial processes. There was superficial metastasis along the subepithelial lymphatics more or less parallel to the surface epithelium. Such growths were rather uncommon, but it was conceivable that that would yield to curettage. As to whether a rdical operation should be done in the early stages of cancer of the uterus they had Schottlaender's report of eight very early cases of cancer of the uterus in one of which there was metastasis in the regional lymph nodes. The mortality from operation in these eight cases was *nil*. The ultimate prognosis as a result of hysterectomy was certainly improved, and at the present time no one would be satisfied with curettage alone as a cure even of the earliest cases of cancer of the uterus.

Dr. Herman J. Boldt stated that while the cases reported by Dr. Ladinski were interesting there was but one, and that was the second, that offered anything not heretofore known. All the other cases bore no analogy to his case number two. That case had been reported by him at the January meeting, and was the only instance that was unusual and not intelligible to him. All the cases reported by Dr. Ladinski were early cancers, cancers in the earliest stage, that had not passed the boundaries of the mucosa, or they were polypi. Such instances they all regarded as possible of cure by curettage. The case reported by Dr. Boldt was not an early cancer nor a polypus, and to show that this case was unique Dr. Boldt read the reports of the pathologist of Beth Israel Hospital and a part of a letter from Dr. Thomas S. Cullen confirming the diagnosis of adenocarcinoma. The specimens were examined by a number of well-known pathologists in this country and in Europe, and all considered it likely that there was a "mix-up" in specimens which sometimes happened even with the utmost care. Dr. Boldt said he wished to protest against the statement that he had said that this patient never had cancer and that not even a curetting had been indicated. A curetting for diagnosis was positively indicated. He had said that there was no evidence of cancer and certainly not an indication for hysterectomy.

Dr. Ladinski said that in regard to Dr. Taylor's statement, he had also been of the same opinion that it was inadvisable to do a preliminary curettage for a fibroid, but since his study of these cases and his experience in one case, he had changed his opinion and was in favor of preliminary curettage. He cited the case of one patient who had had a supravaginal hysterectomy done by another surgeon, four years ago, for fibroid which later turned out to be adenocarcinoma. A preliminary curettage would have discovered the presence of cancer. Her suffering had been intense ever since; she was operated on one year ago for intestinal obstruction. The suffering of this patient had convinced him that a preliminary curettage was very valuable and added no risk or special danger in such cases. As to the differences in the findings of the pathologists, he was not discussing these differences any more than he was discussing the differences of opinions of different diagnosticians; he was presenting scientific facts as reported by men preeminent in gynecology and pathology. He had not reported any case when there was a question as to the difference of opinion of pathologists, but reported only what was accepted without question by all pathologists. The question for discussion was in regard to the removal of the uterus after carcinoma had been totally removed by the exploratory curettage. It would be false doctrine, especially when we were trying to instruct physicians and the public in regard to the necessity for early diagnosis and treatment in cancer, to teach that in cases of this kind there should be procrastination.

The Freiburg Method of Producing "Twilight Sleep."—Dr. W. H. W. Knipe read this paper. (See page 967.)

Report of a Series of Cases in Which the "Twilight Sleep" Was Used.—Dr. Ross McPherson and Dr. James A. Harrar presented this report, which gave the results of their experience with this form of amnesia. What they had endeavored to show, if possible, was whether this method provided a safe form of amnesia for both mother and child in a sufficiently large number of cases to make the study of the technique of its use worth while, and whether or not by or after effects were developed which would contraindicate its use. The technique which they had used was that of Gauss and Kronig down to the finest possible points, and this was the technique which Dr. Knipe had just described. The cases were in most instances from the wards of the New York Lying-In Hospital, although there were included several private patients. There were in all 115 cases, all primiparæ. Complete amnesia was secured in 75 of these patients; partial amnesia in 11, and in 25 there were no results. The four remaining were too far advanced in labor to derive any benefit from the drug. In nearly all of the cases in which amnesia was secured the treatment was started three to seven hours before the termination of labor. There were no bad results that could be attributed to the use of the drugs so far as mortality was concerned. One mother developed a rapid weak pulse (140-160) for two hours after delivery, with slight delirium, but soon became normal and showed no ill effects the day following. The case was perfectly successful so far as effacement of the memory was concerned. There was no asphyxia attributable to the treatment and no hemorrhage post-partum of any moment. The average duration of labor was somewhat shorter than in cases not receiving the treatment. They had noted in general a more rapid dilatation of the cervix than usual, with a somewhat slower second stage than was normally expected. This, however, had given rise to fewer lacerations of the perineum, and when the delay seemed too long it might be shortened by the use of pituitrin. In the first one hundred

cases there were seventeen forceps extractions in the scopolamine cases compared with eleven in the untreated cases. Eight of these seventeen operations were for the arrest of the head at the outlet and strong pains would have been required in any case. Six of the remainder were due to inertia at the outlet, and could now be avoided by the use of pituitrin. The involution of the uterus and the puerperium were in all cases uneventful. In conclusion Dr. McPherson said that it seemed that in 60 or 70 per cent. of cases they had a very valuable method of abolishing a woman's recollection of pain during labor provided the described technique was carefully carried out, the cases carefully chosen, and the drugs reliable and stable, the last being of great importance. It was not a method which could be employed without considerable study of the technique and patient attention to detail, and was better carried out in a hospital than in a private house, unless the circumstances of the patient warranted the transference of a complete working force to the house. The employment of these drugs in no way lessened the necessity for obstetrical skill, but rather increased it. In short, they had here another valuable therapeutic aid for their armamentarium which in indicated cases was of much value, but which was not a panacea for the pains of labor, and had not yet reached the stage of perfection which made childbearing an entirely enjoyable process.

Dr. Abraham Rongy said that one should not take an obstetrical case and tell the patient that she would go through a painless labor, for it was not a painless labor, but an attempt to get the patient into a state of amnesia; this was the guiding point of the Gauss method. The patient did not remember the pain, and hence was as well satisfied as though she had never gone through it. In their series of 230 cases 80 per cent. of the children suffered from slight oligopnea. The first stage of labor was shortened, the second prolonged. The degree of hemorrhage was unaffected. The method was more applicable to primiparæ as in multiparæ the time was too short. In the event of the head being delayed at the brim of the pelvis they used pituitrin guardedly.

Dr. Samuel W. Bandler said that before going so far afield in the discussion of this method it would be well to ask themselves the simple question, "What do we gain?" It seemed that the labor lasted longer with this method than under normal conditions, and even though the patient forgot that she had had pain, "What have we gained?" In his experience he had not found women unwilling to undergo a second childbirth because of the pain experienced in the first. He had had a large experience with a pituitary preparation, and used it with few exceptions in the second stage of labor, as it lessened the duration of the second stage by about one-half, and he had never seen a case of asphyxiation from its use. He had used morphine, scopolamine, and hyoscine as long ago as eight years. During eight years he had tried morphine and hyoscine in atony before a forceps operation, but only in a few cases had he used these drugs according to the recent methods, but he believed that morphine, hyoscine, and scopolamine inhibited the action of the pituitary product, and if one used these drugs the addition of the pituitary did not shorten the second stage of labor. With the use of pituitrin he now had one forceps case where formerly he had four or five; not only was the duration of the second stage shortened but asphyxiation did not exist. Dr. Bandler felt assured that the oligopnea reported was due to morphine and hyoscine.

Dr. James A. Harrar said that the speakers seemed to be pretty well in accord as to the efficacy of the "twilight sleep" when the technique of Gauss and Kronig was carried out. In his experience the general effect on the labor had been a rather more rapid dilatation of the cervix than usual with a delay on the perineum. This delay, if the fetal heart was carefully watched, was in the main beneficial for the mother, resulting in a marked diminution in the number of perineal lacerations. There were thirty-seven in the first one hundred primiparæ delivered under the scopolamine seminarcosis, as against forty-five per hundred as the average in the Lying-In Hospital records in ordinary primiparous labors. Getting the patient under the influence of the drug must be gradual with the minimal dose in each case that would produce the desired effect. Examination of the mother's urine before and after labor had not shown any bad effect on the kidneys. The involution was not hastened in any way and no reason was seen for getting the patients up any earlier than was customary. From his experience he was impressed that any harm that came to the child under this treatment conducted strictly according to the technique outlined was the result not of scopolamine, but of bad obstetrics. Even better obstetrical knowledge and judgment than usual was necessary, and abdominal and vaginal examinations must be carried out as in any labor. There were two important and not uncommon difficulties that demanded attention. The first, delay on the perineum, which must be corrected with forceps, if necessary, as indicated by the condition of the fetal heart. The indiscriminate use of pituitrin for this purpose was to be condemned. Undoubtedly it was responsible for some still births where scopolamine had not been used, and there was no reason to believe it would have any better effect in these scopolamine patients. The babies that were born with more or less asphyxia were chiefly those in which there had been a delay on the perineum. This percentage was not above the average observed in primiparous labors, and these babies all promptly revived. The percentage of still births was the same, two to one hundred. The second disadvantage was the frequent development of delirium as the head distended the vulva. This was partly due to the commotion of moving the patient to the delivery table and partly to the increased pain. It was this restlessness that made him hesitate to undertake this method in a private house unless there was an abundance of trained assistance. There were certain limitations to the extensive use of this method in hospitals; it was a suitable treatment in less than 10 per cent. of the admissions. The time and attention required might be said to have been the chief obstacle to a wider use of the method. Many women came in too far advanced in the second stage to begin the scopolamine. Primary inertia he considered an absolute contraindication to this treatment. Its use was also to be avoided in cases in which operative interference was anticipated, in ante-partum bleeding, and in bad lung and kidney cases.

Dr. Robert L. Dickinson of Brooklyn said that it seemed to him that with the "twilight sleep" the patient was under the influence of belladonna poisoning; she was excessively thirsty and apt to be restless or delirious just when it was necessary to have her quiet, for how could one sew up a perineum with the patient in such a restless condition? It was evident that the method had a place and the time was coming when it would be used in every primipara. At present it was difficult to conduct the treatment properly, and it belonged entirely to the skilled obstetrician and not to the public.

Dr. George P. Shears said that the paper was so clear, so logical, and so moderate that he felt that he had learned something, but he wondered whether, after all, "The game was worth the candle," as there was no suffering that faded from the mind so quickly as the pangs of childbirth. In the twelve or fifteen cases that had come under his observation the effect on the mother was wonderful, there being no subsequent hemorrhage, no relaxation, and a rapid recovery. The danger was to the baby, and when one considered the effect of the morphine, the hyoscine, the chloroform, and possibly ether, it was putting too much strain on the imagination to expect one to believe the baby was better under such conditions.

Dr. Samuel J. Druskin stated that Dr. Crile had well demonstrated the effects of insomnia, anxiety, and violence; this method eliminated the anxiety and one should not underrate the importance of effacing from the mother's mind a disagreeable experience. Dr. Druskin said he preferred to use pituitrin. While it was somewhat weakened in its effect by the morphine and narophine, it nevertheless gave sufficient contraction to cause the expulsion of the child and the mother might be able to give some assistance if the drugs had been properly given. He had used the method with safety in cardiac and kidney cases.

Dr. Ross McPherson, in closing the discussion, said that in regard to what Dr. Bandler had said as to the time of labor, in their series of cases the total duration of labor was two hours shorter on an average when the scopolamine was used than it was in a like number of cases in which no such drug was used. So it seemed that instead of a prolongation of labor the use of scopolamine actually shortened the total duration of labor. As to the statement that he did not hear of patients not wishing to have a second child because of the pain endured during childbirth, every one who had an experience of any extent learned that quite the

contrary was the fact, that many women came asking for abortions because they could not again endure the awful suffering that they had experienced in the first labor. One had but to see these patients who had experienced the "twilight sleep," to hear them and their husbands express their gratification, to realize what this meant to all concerned. As to the comparative value of narcophine and morphine, he thought that the latter possessed rather the advantage and it was easier to obtain. There was one point mentioned about which he disagreed, and that was early rising after childbirth. He felt convinced that early rising tended to subinvolution, and these were the patients who came back later with gynecological troubles. The patient should remain in bed until subinvolution was complete. As to the effect of the "twilight sleep" on involution, he could not say that it shortened the period of involution, but it certainly did not lengthen it. He did not use exercises during the puerperium to the extent that Dr. Knipe had indicated.

Dr. Samuel J. Scadron said that he had had under observation about 250 cases in which the "twilight sleep" had been used and had seen no untoward effects on the mother or child from the use of scopolamine. He believed that scopolamine had no cumulative action. It appeared in the urine from fifteen to twenty minutes after the first hypodermic injection. By the time the third dose had been administered the first had lost its effect and was out of the system. He had had one case twenty-eight hours in twilight, the patient receiving nineteen injections of scopolamine and one dose of narcophine; this was a very successful case, as the mother had complete amnesia and the child cried immediately after delivery. The speaker emphasized the dangers of the pituitary preparation, especially when used in combination with scopolamine and morphine. If the pituitary extract was given simultaneously with the scopolamine it had an effect on the infant, but if it was administered one-half hour after the scopolamine no bad effect was observed. Some of the patients receiving this treatment were allowed out of bed forty-eight hours after delivery, and were discharged from the hospital on the fifth day. Subsequent examinations showed the uterus well involuted, in normal position, and the general condition of the patients very good. This rapid recovery he attributed to the fact that the "twilight" patients showed no signs of exhaustion after labor and received daily exercises as described by the reader of the paper.

Dr. Ephraim K. Browd said that he had had a large experience with the pituitary preparation in dystocia, and was of the opinion that if the cervix was imperfectly dilated its use was contraindicated and its effect upon the child was dangerous. The employment of pituitrin was limited to the second stage of labor and dystocia; its effect was that of an oxytoxic, while the action of scopolamine was that of a hypnotic, and might be used from the beginning of labor; the action and employment of both drugs were distinctly different. Scopolamine would prove useful in cases of cardiac, pulmonary, or renal disease, or in cases of extreme anemia or neurasthenia, or in cases in which anesthetics could not be used. We had not been told how far this method was applicable in cases of malpresentations or malpositions. The asphyxiation of the child, he believed, was due more to the child's head resting on the perineum than to the effect of the scopolamine. All these questions would have to be worked out and the "twilight sleep" should be given a fair trial.

Dr. Alfred Hellman said he had gone to Freiburg rather prejudiced against the "twilight sleep," but he was rapidly converted and had become very enthusiastic. The enthusiasm of the women who had received this treatment would soon lead one to champion its use. Many of the women asserted that their labor had been painless or at least they had no memory of the pain; in some instances those present thought the woman had suffered pain, but she would have no recollection of it. Dr. Hellman had been impressed with the rapid recuperation that took place in the women receiving this treatment. They did not suffer from the great exhaustion as did those who had been through a long labor, and the uterus returned to normal much earlier. The danger to the child had been dwelt upon, but the babies could all be revived and Kronig believed that the delayed breathing was often valuable because it prevented breathing before the birth of the head.

Dr. W. H. W. Knipe, in closing the discussion, said that if the method was properly applied there was no asphyxia. At first about 25 per cent. of the babies had oligopnea, but now they were practically unaffected. He could not understand the statement that the second stage of labor had been prolonged by one-half; in their series of cases the total duration of labor had been reduced. The delirium had been very little, and might be due to moving the patient to the delivery table; it was better to leave the patient in bed. With proper dosage the thirst and restlessness were reduced to a minimum. The after care of these patients was not different from the after care of other obstetrical cases. They had used the "twilight sleep" on patients having cardiac lesions, but not where there was a lack of compensation.

SECTION ON PEDIATRICS.

Stated Meeting, Held October 8, 1914.

Dr. William P. Northrup in the Chair.

Infantile Scurvy: The Blood, the Blood Vessels, and the Diet.—Dr. Alfred F. Hess presented this paper, in which he related the results of a study in scurvy, the observations having been made at the Hebrew Orphan Asylum and the research work carried out in the Research Laboratory of the Department of Health. Attention was especially directed to the study of the coagulability of the blood with the object of ascertaining whether there was any marked change in this particular and whether a disturbance of this function could account for the various hemorrhagic symptoms of scurvy. In this series of cases they had the clinical data covering a long period before the development of the disease and they had been able to follow the infants for many months following their recovery. A number of these cases developed in the course of an attempt to do away with the giving of orange juice. In no case was the blood test made from blood obtained from the prick of a finger or the lobe of an ear, since these methods mighht introduce the disturbing factor of the thromboplastic substance of the tissue juices and this did not yield an accurate estimate of the coagulability of the blood itself. The coagulation tests were carried out after the method of Howell, which was by the addition of five drops of plasma to each of five small test tubes. To these tubes increasing amounts of one-half per cent. calcium chloride made up in normal salt solution were added. The time was then noted when the plasma in the various tubes were clotted. After describing his method for testing the resistance of the capillaries and affirming his belief that it was to this lack of resistance that the petechiæ so characteristic of scurvy were due, he noted that these petechiæ were found in the mucous membrane of the hard and soft palate and in several instances in the palpebral conjunctiva. The blood in the urine might probably be considered as evidence of petechiæ into the internal organs. In post-mortem examinations small hemorrhages had been found in the pleura, peritoneum, and pericardium. Edema was also typical of an increased permeability of the vessels. A comparison of scurvy and hemophilia brought out a striking contrast. In hemophilia petechial spots were not found scattered over the surface of the body, nor was edema a symptom of the disease. On applying the capillary resistance that it was found that petechiæ were not induced by this increased vascular pressure. In other words, in hemophilia the vessels seemed to be normal. In scurvy the hemorrhages were usually minute and numerous, in hemophilia they were few and extensive. A point at times of value in the matter of diagnosis was that in scurvy a little sharp rubbing of the gums frequently produced slight hemorrhages. According to their experience the infectious diseases did not play an essential rôle in the production of scurvy. Dr. Hess summarized his study as follows: Infantile scurvy was a disorder characterized clinically by hemorrhage; for example, the classical bleeding into the gums and the subperiosteal hemorrhages of the long bones. A study of the cause of this bleeding, which must include a consideration of the clotting power of the blood formed the nucleus of this investigation. For the coagulation tests blood was aspirated directly from the blood vessels and ozylated. This plasma showed a slight diminution in clotting power. The nature of this defect was not ascertained; however, it did not seem to be the result of an insufficiency of calcium, nor was the antithrombin increased. Small amounts of blood were also obtained by puncture of the finger. Examinations of this blood revealed a normal number of blood platelets.

In other respects the picture was that of a simple secondary anemia, excepting that the hemoglobin was diminished out of proportion to the red blood cells. A marked regeneration of these cells during convalescence, leading to a polycythemia, was also noticed. These various departures from the normal were insufficient to account for the hemorrhages associated with the disease. The integrity of the blood vessels was therefore investigated by means of a device which might be termed the "capillary resistance test." This test consisted in subjecting blood vessels and capillaries of the arm to increased intravascular pressure by means of an ordinary blood pressure band and of observing whether this strain resulted in minute leakage of blood through the vessels—the appearance of petechial hemorrhages into the skin. The vessels of normal infants were found to withstand, without apparent disturbance, ninety degrees of pressure for three minutes, whereas the vessels of infants suffering from scurvy gave away under this pressure. This test was not specific for scurvy, but was a method of demonstrating a weakness of the vessel walls, whatever might be its cause. In the course of an exceptional opportunity to observe scurvy in its incipiency, numerous petechial hemorrhages of the skin or mucous membrane were frequently noted as one of the earliest signs of the disease; no sign, however, should be regarded as preeminently the primary symptom of scurvy. It was generally recognized that scurvy had not only an exciting cause but a predisposing one. The well known "exudative diathesis" of Czerny was found definitely to predispose to the development of scurvy. Whether there were other predisposing factors remained to be determined. Several cases of scurvy developed in infants who were being fed on milk which was pasteurized to 145° F. for thirty minutes. They were cured by receiving fruit juices or raw milk. Orange juice was found not to lose its efficacy as the result of being boiled for ten minutes. The juice of the peel was successfully substituted as an antiscorbutic for the juice of the orange. Potato proved to be an excellent antiscorbutic. It was suggested that it be added to pasteurized milk as potato water instead of the barley water which was now commonly used as a diluent. In this way the necessity of giving orange juice would be obviated. Cod-liver oil or olive oil, although given for weeks, did not prevent the development of scurvy.

Dr. SIDNEY V. MASS expressed his pleasure in hearing so interesting a paper, but said there were a few points on which he disagreed with Dr. Hess. One of these was that the "exudative diathesis" was an important etiological factor in scurvy. In hospital and dispensary practice from fifteen to twenty per cent. of all cases had the "exudative diathesis," although there was no disease rarer among this class of patients than scorbutus. The observations on which the paper was based were made in an infant asylum and it was well known that where either infants or adults were collected in large numbers this disease was apt to be more prevalent. It was interesting to know that the disease had been observed so early in life. At the infant asylum they had had the experience that after cutting out orange juice with 200 children, 65 of the number suffered from gingivitis or stomatitis; with the return to orange juice the cases all cleared up within two weeks.

Dr. WILLIAM P. NORTHRUP said that in his experience it seemed that subjecting milk to hard boiling was a factor in the production of scurvy. There was no scurvy if the child had the witching drop of orange juice. There were three conditions in which the pediatrician could do miracles; one was with orange juice in scurvy; another was thymus for cretinism, and the third was intubation for diphtheria of the larynx. Dr. Northrup asked if there was a possibility that infection might play a part in the production of scurvy.

Dr. J. FINLEY BELL of Englewood, N. J., said that he had had a case of scurvy about three months ago which had been fed on nine cent milk. It was claimed that this milk was not twice heated. The child recovered after about three weeks' treatment with orange juice.

Dr. WILLIAM P. NORTHRUP related an instance of two infants nursed at the same breast, one a nursling and the other the mother's own child. The mother's child was fat and healthy, while the nursling developed scurvy. The phenomenon of scurvy was so distinct, yet so difficult to explain, so easily cured and yet the most extraordinary which the pediatrist saw. Dr. Northrup recalled that he had reported the first eleven cases occurring in American practice to the American Pediatric Society. He had seen the first case at the Foundling Hospital, and a pathologist had diagnosed it syphilitic hemorrhagic periostitis. Dr. Van Sandvoort said it reminded him of a case in which the child had eaten chalk, sand, and other articles of an inedible nature, and at autopsy they concluded that the child had had scurvy; he did the same. One found cases of scurvy in well-groomed families where the greatest care was taken of the child's diet. These children, too, recovered on orange juice.

Dr. ALFRED COLE WALLIN made reference to an article which he had written on the subject of scurvy which appeared in *Pediatrics*, August, 1914, in which he gave confirmatory evidence of the theory that scurvy was an acquired disease, with a hemorrhagic diathesis, from improper feeding causing alkalinity, and that most cases had symptoms of indigestion of an alkaline nature. He stated that he had seen four cases of scurvy in breast-fed infants within the past nine months and that he attributed them to the alkalinity of the mother's milk. The children were entirely breast fed with the exception of one, which was partly breast fed and partly bottle fed. They ranged in age from four to eight months.

Dr. NORTHRUP said that after a full discussion of scurvy he had once asked Dr. Ripley whether he had not in his vast experience run across similar cases (Dr. Ripley, by the way, was an old friend of Dr. James O'Dwyer and was sometimes called a specialist in all lines, so well informed was he). Dr. Ripley said he had seen such cases, had called them sometimes acute rickets, sometimes syphilitic osteitis, treated them wth citrate of potash and mercury, and after a time cured them.

Dr. ALFRED COLE WALLIN stated that he had seen several cases of scurvy which were fed on pear juice and they seemed to get worse. He thought this was possibly due to the alkalinity of the pear juice, and asked Dr. Hess what his opinion was as to the reason.

Dr. NORTHRUP referred to the last case of scurvy which he had seen and stated that the child developed the disease on a malt soup diet. He concluded that there were many different foods that might cause this condition, and that it was the unvaried monotony of various foods that might produce it.

Dr. ALFRED F. HESS said that he had read what Dr. Caillé had written in the report of the American Pediatric Society. He had observed the condition characterized by some leucocytosis, and slight fever, what the Germans called Barlow fever. The fever was slight and there was no epidemic; it was difficult to picture an infectious disease being controlled at will by means of orange juice. They had considered making tests of the alkalinity of the blood, but such tests seemed so uncertain that they had not been done; they did not seem to promise enough. He felt sure that with the pear juice it was not the alkalinity that caused the trouble; but why use pear juice when orange juice was so satisfactory? As to the question whether he had undertaken any animal experiments—he had not done so as such experiments could not show more than that orange juice was a curative agent, and that had been demonstrated on human beings. He had observed that scurvy occurred more frequently in private practice where infants were well cared for. The institution in which he had made his observations was an excellent one, and this must be taken into consideration in connection with the facts presented. They had used one tablespoonful of mashed potato to one pint of water and this prevented the onset of scurvy.

Dr. ROYAL STORRS HAYNES asked Dr. Hess whether he had observed purple gums before the eruption of the teeth, and also whether after the teeth had come this phenomenon appeared first before or behind the teeth, the occurrence of the hemorrhage into the gums behind the teeth being characteristic in Dr. Haynes' experience, and perhaps being due to the pressure of the tongue against the gum in that situation.

Dr. ALFRED F. HESS replied that he had never seen the purple gums unless the teeth were erupted or about to erupt. He had never seen them where there were no teeth coming through.

Dr. J. FINLEY BELL of Englewood, N. J., observed that there might be danger from the potato water as there might be solanum in the water in which the potato was boiled.

Dr. HESS replied that if that were demonstrated the

water in which the potato was boiled should not be used, but that they had never had any unpleasant results from its use.

Dr. NORTHRUP reiterated the belief that it was the deadly monotony of an insufficient diet that was responsible for this condition and that any fruit juice or other change that broke up the monotony might be curative. He asked Dr. Hess whether in their study of the coagulability of the blood they had used any other drug beside calcium.

Dr. HESS replied that the only drug used was calcium and they had found that there was already enough of that in the blood.

Dr. NORTHRUP said that the most puzzling thing was that infants nursed at the mothers' breast could have scurvy and cited an additional instance of an infant in a well-to-do family that developed scurvy under the most assiduous attentions of a nurse.

Therapeutic Hints.

Atropine Methyl Bromide in Pediatrics.—Breitman discusses the advantages over atropine sulphate of the above compound, a crystalline substance soluble in water or dilated alcohol, and having a bromine content of 20.8 per cent. The chief advantage is the slighter toxicity, which permits of the administration of larger doses. The chief indications for the use of this compound are the exudative diathesis and the moist eczema of infants. In the latter condition the daily dose is 0.001 gram. This dose may be increased, some German pediatricians giving as much as 0.005 gram per day. Among the complications of the exudative diathesis atropine methyl bromide is particularly serviceable in chronic bronchitis, in bronchopneumonia, and in the digestive disturbances. It is also useful in the treatment of convulsions and of the nervous manifestations of rachitic origin, particularly laryngospasm. The antispasmodic property of atropine methyl bromide is more pronounced than that of atropine sulphate in the treatment of ileus, mucomembranous enteritis, and sigmoiditis resulting from coprostasis. In enuresis nocturna the author administers a mixture such as the following:

℞ Atropine methyl bromide, 0.003 gram,
Aromatic tincture of rhubarb, 10 grams.
M.S.—10 drops three times a day.

In the last-mentioned condition the action of atropine methyl bromide is more effective than that of atropine sulphate. Similarly good results are obtained in angioneurotic edema.—*Pediatrija.*

Treatment of Tuberculosis of the Bladder.—Carmelo Bruni notes that Casper regards instillations of corrosive sublimate in a strength of 1 to 10,000 gradually increased to 1 to 2,000 as the best local remedy in this condition. The painful reaction following these instillations frequently demands the use of opiates. The author has had little success with the above method of treatment and prefers the use of gomenol, which is particularly advantageous because of its analgesic power. It is used in a 10 per cent. strength mixed with a bland oil and may be instilled daily. Another good remedy is guaiacol, which is a powerful analgesic and is instilled, as in the following formula:

℞ Iodoform, 1 gram,
Guaiacol, 5 grams,
Sterile olive oil, 100 grams.

It should be borne in mind that nitrate of silver, which is the best topical application in other forms of cystitis, is injurious in the tuberculous variety.—*Riforma Medica.*

The Medical Treatment of Hypertrophic Pyloric Stenosis of Infants.—L. Exchaquet outlines the following measures recommended by Ibrahim, as follows: Administer a food both easily digested and nourishing: milk modified with cream or a malted cereal, buttermilk, or sweetened skimmed milk. Use a small quantity of food at a time. Lavage rids the stomach of residues that favor vomiting and other dyspeptic disturbances. The spasmodic element may be combatted by the application of hot compresses and by the administration of valerian, opium, and atropine. The general strength may be sustained by the use of saline and nutrient enemata or by hypodermoclysis. Whenever possible the pylorus should be stretched by means of the method of pyloric intubation devised by Hess.—*Revue Médicale de la Suisse Romande.*

MANAGEMENT OF THE PNEUMONIA PATIENT.*

BY SIMON BARUCH, M.D.,

NEW YORK.

FOR several years I have entertained the idea of investigating the reasons for the fatality of pneumonia and more especially for the dictum expressed by some conservative writers and speakers that the prognosis of pneumonia remains unaffected by any method of treatment. That this pessimistic view is incorrect has been demonstrated to my satisfaction by personal experience which extends over a period of half a century, during which my methods have passed from the antiphlogistic attack on the disease through all modern "improvements," until I have reached the present policy of managing the patient by sustaining his resisting capacity rather than battling with the disease.

The study of several articels, mostly by teachers of medicine, which have appeared during the past year, has furnished a clue to the solution of this question that may serve to point a valuable lesson for us. These articles really present the views of the average textbook on practice. I shall designate them by numbers.

While they claim progressive ideas, most of the authors lack positiveness and display contradictions that serve to confuse rather than help us to reach rock bottom in this serious problem.

No. 1, in treating of bronchopneumonia, insists upon heat and ventilation, regards hot flaxseed poultices of great service, does not use ice bags, sponges the body twice a day with tepid water, never uses antipyretics, and feeds the patient every second or third hour. He opens with calomel or castor oil, and mentions as more or less useful the following drugs: Large dose of quinine hydrochloride intramuscularly, opium, camphor, digalen, musk, cocaine, epinephrin, atropine, pituitrin, caffeine, strophanthin, apomophine, ipecac, ammonium, iodide in a pepsin vehicle, injections of iodide in vasogen, iothion in olive oil, Besredka's pulmonary autogenous vaccine, and mercurial inunction in extreme cases. In convalescense he advises "food, fresh air, and water, with perhaps tonics."

No. 2 advises in bronchial and lobar pneumonia rest, *water in abundance*, and a gradually increasing feeding. He is a thorough believer in exposing the patient, while the body is kept scrupulously warm, to outdoor, live, moving air, which he very properly regards as a stimulant to the vasomotor centers, keep the bowels open, regards fever as not to be treated, except when imperilling the vital centers. Hyperpyrexia is to be combated *"not by drugs, but by cold water."* How applied, he fails to state. He gives caffeine, camphor or digitalis early in 20 to 30 mgm. doses.

No. 3 insists upon good nursing and hygienic conditions and replaces the windows by cheesecloth or rugs. He uses, as occasion demands, guaiacol, quinine, spartein, hexamethylenamine, aspirin, digitalis, strychnine, camphor, oxygen, also vaccines, icecaps for delirium, whiskey, occasionally sponging for high temperature, with water at 98°, gradually reduced to 65°, allowing it to evaporate.

No. 4 treats croupous pneumonia of children with warm tub baths for high temperature with nervous symptoms; does not urge food; regards alcohol as best cardiac stimulant, in addition to digitalis and caffeine. No local applications.

No. 5, in bronchopneumonia of children, depends upon apomorphine, combined with strychnine to keep the bronchial tubes clear, brandy and sometimes the iodides and digalen hypodermatically; has no faith in local remedies; sometimes uses cotton jacket.

No. 6. In the most elaborate article that has appeared in recent years, the author bases his conclusions on the records of one of the largest hospitals in the country in which medical students are taught. In lobar fibrinous pneumonia he claims recovery is approximately 75 per cent. He exposes the patient outdoors, protected thoroughly in a woollen sleeping bag, except the nose and mouth. He warns against cold air as fatal in bronchopneumonia, with low temperatures, and gives as little food as possible. He regards drinking water as an essential, "not less than three pints in twenty-four hours and as important as fresh air." Sweeping the intestine every second day with castor oil is valued. *Recommends sponging with hot water morning and evening and at regular intervals, at as high temperature as the patient prefers. Regards the hot sponge bath* as a cardiac tonic. Recommends hot turpentine stupes of 15 minutes' duration; dry cupping once a day; hot foot baths are of advantage. Hypodermoclysis is condemned because "we should spare the cardiac muscle the additional burden of an overquantity of fluid in the circulation." Occasionally he applies an icebag to the precordium, sometimes over a blister, to quiet the heart. Although he claims that many patients would be better without than with extensive drug treatment he mentions as more or less applicable hypodermics of atropine as a cardiac tonic, maltine and morphine for the cough and restlessness and to quiet the heart; pilocarpine for skin elimination; strychnine, digitalis, spartein, camphor, ammonia, and a calcium salt may be employed without expecting too much of them. Alcohol he regards as a vasomotor paralysant. He concludes that "if treatment is conducted along these lines recoveries should occur in vast numbers in healthy persons.

*Read at a meeting of the Section on Medicine of the New York Academy of Medicine, October 20, 1914.

The author concludes as follows: "There is no question that many pneumonia patients are hurried if not helped, into the grave by overtreatment. 'Purging, diet, and bathing' were the watchwords of Asclepiades. Add both warm and cold air to this triad and we shall have the outline of the most successful modern treatment of one of the most treacherous and dreaded forms of systematic and pulmonary disease." Let us see how the detailed methods and the statistics bear out these optimistic propositions: "Total number of cases from 1911 to 1913, 596; deaths, 364; mortality, 61.3 per cent.; number of cases with temperature not over 100°, 393; number of cases typically fabrile, frankly croupous, 203. The majority perhaps occurred in alcoholic subjects. Practically every case was treated in cold fresh air; very many on bridges constructed for the purpose."

These statistics certainly do not justify the author's optimistic attitude, for they present the second highest mortality I have encountered in the literature of the subject. While the principles enunciated are correct academically, the practice is at fault in their incorrect application as I shall show presently.

It would appear from this symposium of teachers that all the conventional modes of therapy have been applied according to the text-books, just as is claimed in another article by a general practitioner in a small city, who without stating the number of cases treated, claims to have had a mortality of only seven in twenty-four years. His treatment is "fresh-air, outdoors if possible; patients lying on a single bed; diet of milk, ice-cream, fruit juices, custards, beed-juice in small amounts; water every two or three hours; bowels cleared with a dose of calomel at the beginning; skin to be kept active by a quick cold sponge, followed by a rub." He is the most active hydrotherapist I have ever encountered; recommends "cold and hot packs or ice around the chest every fifteen or twenty minutes until the pulse, temperature, and respiration are decidedly impressed; then at longer intervals when the temperature goes below 102°F.," etc. The details of this singular hydrotherapy will be discussed presently. He does not use alcohol.

The Lesson.

What lesson may we derive from a brief review of the methods advocated in these articles, most of which differ in no wise from those recommended in the average text-book or society discussion?

1. All claim to treat the patient instead of the disease. This is a great advance over the spoliative methods which in the antiphlogistic period of medicine killed the patient or brought him out of bed in a damaged condition from which he recovered slowly, sometimes not at all. And this is a great advance also over the happily brief antipyretic period from which we are barely emerging now, in which the chief difference was that the patient died with a lower temperature than formerly.

2. *Food.*—Upon this subject most authors agree also. I would protest against overfeeding, especially in croupous pneumonia. The recent trend to overfeed or at least abandon former caution in typhoid fever may lead to similar change in the feeding of the pneumonia patient. Let me warn against this idea. We must guard against the not infrequent distention of a paretic intestine. When there is a tendency to gaseous distention, food must either be given in moderate quantities or withheld altogether. Since the attack is usually ushered in suddenly in a healthy individual and its duration is limited, this precaution against a too little heeded handicap to respiration is without danger. Each case presents its own problem in this as in other features. I refer only to general principles.

3. *Drink.*—Water in abundance is advised by those who mention it at all. One author advises "at least three pints daily but in another part he properly warns against hypodermoclysis," because "we should spare the heart muscle the additional burden." I am convinced that not the *quantity* but the *temperature* of water stimulates the emunctories and does it through vasomotor enhancement. Guided by ample bedside experiment I prescribe two to four ounces of ice water—not above 40° F. every two hours. I order a few drops of diluted hydrochloric acid or other placebo to be added to impress its importance and a record to be made of the quantity taken and retained. The result is enormous diuresis as will be dwelt upon later.

4. *Fresh Air.*—That pure air is vital to the pneumonia patient is indisputable, but that pure air may be procured only out in the open is fallacious. While it is true that in a crowded school, for instance, as has been shown by Dr. J. F. Rodgers (MEDICAL RECORD, 1914), ordinary window ventilation does not prevent serious contamination of the air, this fact does not apply to a sickroom containing one patient and attendants. It does apply however to hospital wards. Pneumonia like most infectious diseases demands not only fresh air but, as one of these writers has well expressed it, *cold moving air,* if it can be obtained. The reason is doubtless to be found in stimulation by the cold air current of the skin of the face and the mucous membrane of the nasorespiratory surfaces. That this stimulation may be procured indoors also has been proved by the interesting experiments of Fluegge, Leonard Hill, and Henderson of Yale, who, confining a number of persons in an air tight compartment furnished with thermometers and an electric fan, found that when the rebreathed air reached 80° F. and became humid, all the occupants suffered depression but that they were revived immediately upon stirring the air with a fan.

In hospital wards or houses in which a sleeping porch is unattainable, one or more fans and strict attention to having the air below 70° F. and fairly dry, may secure the advantages of open air. In the better class of city dwellings, apartments and in hotels also this arrangement may be substituted for the open porch. I would specially favor it because it would not exclude the application of another and better vasomotor stimulant to be presently referred to. That precision in the technique is as important in this fresh air treatment as I have but too sadly learned it is in the water treatment, is illustrated by one of the articles quoted. The author states that of the 593 cases treated about one-half were of the frank croupous type, with temperature above 100°F., and the other half of lower type—mostly bronchopneumonia with temperatures below 100°F., and that "practically every case in the series was treated in cold fresh air." And yet in another part of the article he writes "it will be safe in fibrinous pneumonia with temperature above 100° F. to give free rein to the fresh air treatment, but that in possibly the majority of instances (bronchopneumonias) the application of cold air will probably do

harm." This author misses the advantage of the open air treatment anyway by "covering the whole body except the mouth and nose" during the exposure. The fresh air advocate may well cry "Save me from my friends," just as I shall have occasion to say of another of these authors who professes to be an ardent hydrotherapist.

My own method is a compromise. The sashes of one or more windows are removed and the latter closed by blinds, which may be kept more or less open according to the individual requirements. The temperature of the room should not be above 60° F. except when the patient has to be exposed for any purpose. Nurses may protect themselves with extra clothing.

5. *Medication.*—Purgatives are recommended by many. My own preference is for calomel in 6 to 10 grain doses dry in the mouth and washed down after rinsing. It destroys the pneumococci in the mouth and removes all fermenting or toxic material from the gastrointestinal tract. This is my only drug and it is not repeated. The mouth is rinsed with a saturated solution of potassium chlorate every hour. The polypharmacy of some of these writers will, I trust, not find imitators. Heart stimualnts were rarely required in my cases treated early. In consultation cases they have sometimes served a good purpose. Alcohol is needed by alcoholic habitués whose nervous system requires a filip. Strychnine has been shown by Cabot to be absolutely inert in heart failure. I do not advise against it in moderate doses. In consultation a sinking patient who was surrounded by weeping relatives expecting his demise, was saved by withdrawing the glonoin his attendant was plying him with as a stimulant.

6. *Antipyretics.*—Happily the coal tar preparations are no longer dominant in pneumonia. I should not hesitate however to order one dose, six or eight grains of antipyrine in a case of insomnia with unyielding high temperature, to tide over the danger.

"Hot water sponging as a heart stimulant and sponging with water at 98° F. reduced to 65° F. and allowed to evaporate for reducing temperature" do not appeal to my hydrotherapeutic sense.

The warm bath for hyperpyrexia with nervous symptoms would be commendable if the author had stated the temperature and duration and frequency of repetition. There is no procedure for this purpose equal to a tub bath of 90° F., of half an hour's duration for this purpose, the patient being afterward wrapped in a linen sheet and allowed to dry in bed. In most cases of pneumonia of children a ten minute friction bath at 95° rapidly reduced to 80° F. answers all purposes.

The best article of this series states "hyperpyrexia is to be combated not by drugs but by cold water." I wish this author had been as explicit as he was in his contribution to the "American System of Therapeutics," which is a model of clinical instruction. But here he fails to furnish temperature, duration, or method in which cold water is to be administered for the purpose indicated, and herein he is not singular.

One serious obstacle to the popularization of hydrotherapy has been the indefinite counsel on the subject by our best authorities on practice. On this very floor I heard a justly eminent pediatrist say, after entering into the most minute details about the drugs he prescribes in pneumonia, "Whenever the temperature reaches 103°, 104°, 105°, or 106° F. I give cold baths and packs. He said not a word about the temperature, duration, and frequency of repetition of the baths; when the fact is that in New York City the water supplied by the cold faucet is 45° F. in midwinter and 75° in midsummer. I have never dared to give a child a bath even of 75° F. in pneumonia. Most authors and speakers mention cold water only when treating of pyrexia and they seem to regard the coldest bath as the most antithermic. This is physiologically irrational. The best antithermic bath is one at 90° F., of an hour's duration.

The profession is happily beginning to accept my contention of the past twenty-five years that water of low temperature is more useful in typhoid fever for its vasomotor stimulating action than for temperature reductions. I plead for the same idea in other acute and chronic diseases. Its recognition would insure more recoveries from pneumonia, sunstroke, and tuberculosis, and more rapid improvement in neurasthenia and other neuroses.

Another author writes: "We do not as a rule fight temperature with antipyretic drugs. In hydrotherapy we have an agent that should be used as carefully as any of our active drugs. Then he goes on to tell us that "early in the case a cold pack, or ice bag should be applied anteriorly and posteriorly to the thorax every fifteen to twenty minutes until a decided impression is made, which means a continuous renewal from three to six hours or longer, then an hour or more may intervene before another compress is applied. Also cold and hot packs alternately to promote reaction." He writes: "Cold applications if too prolonged or too intense may defeat their own purpose." It is to be regretted that the writer does not practice what he preaches, for this is pernicious activity. How is a pneumonia sufferer to bear these frequent changes of packs and ice and heat without distress and danger? Every principle of hydrotherapy is violated by these irrational procedures.

7. *Local Applications.*—It is interesting to find hot flaxseed poultices, dry cups, and blisters mentioned in modern treatment. While I do not deny their efficacy in the hands of my colleagues I wish that they had given indications for them more definitely.

The only local application that I constantly use is the wet compress at 60° F. applied around the chest every hour, after it has become warm. This is made of three thicknesses of thin or two thicknesses of heavy old linen cut to fit the thorax snugly and to cover the entire chest from the nucha and clavicle to the last rib. It is wrung out of water of 60° F., spread upon a piece of flannel, cut in the same shape, but one inch larger, one-half of the flannel and damp linen is gathered into a fold, the other spread on the bed; the patient turns on one side, the folded part is placed next to his side, so as to reach the nucha at the top; the patient is asked to turn on his back. As he turns upon the outstretched portion of the compress his arms are raised, the folded part of the compress is drawn from under him and is quickly thrown over the chest on both sides; the upper flaps are brought over the clavicle, the flannel is wrapped over the compress and secured by safety pins in front. The patient now lies in a snug cold vest, as it were. The rationale rests upon thermic excitation of the cutaneous terminals, which is conveyed to the central nervous system and reflected upon the heart and lungs, improving the pulse and deepening respiration. In five or more

minutes the temperature of the compress is equalized with that of the skin, gradually the linen warms up and very soon the patient lies in a moderately warm poultice. If oiled silk were used as a covering of this compress it would become a hot poultice. To avoid the relaxing effect of the latter a flannel covering is used, which permits escape of heat and moisture, by capillary attraction, which favors the cooling process. When the compress is found warm on examination with the fingers, after the lapse of an hour, another is prepared before the first is removed. This hourly envelopment of half the trunk in water 40° below that of the skin, produces the following striking therapeutic effects:

Fig. 1.—Application of the chest compress.

1. *Circulation.*—Romberg and Paessler have shown that rabbits suffering from artificial pneumonia die from paralysis of the peripheral arterioles rather than from degeneration of the cardiac fibers. As the four-hourly cold friction baths prevent heart failure in the toxemia of typhoid fever, so does the hourly colder but more evanescent wet application act in the milder and less enduring toxemia of pneumonia. This is proved by the improvement in the tension and rate of the pulse. The pulmonary circulation is probably affected directly, in view of the fact that its vasomotor supply is derived from the second to the seventl dorsal ganglia, which are connected with the epigastric and scapular reflex area in the skin. These are covered by the chest compress when properly made, not otherwise.

2. *Nervous System.*—In the toxic forms of pneumonia the hourly stimulation of the central nervous system is evidenced by a brightening of the countenance and disappearance of dullness of intellect. Intelligent patients have referred to a longing for the time of removal of the compress. Alcoholic or other stimulants have become unnecessary in cases seen early. In consultation cases I have been guided by the temperature, toxemia, and pulse, in lowering or raising the temperature and duration of the compress, being guided by the hydrotherapeutic law that "intensity of action is in proportion to the difference of temperature between the skin and water." For instance, in the desperate case of Dr. J. H. D., whom I had the privilege of seeing with Drs. W. A. Ewing and A. A. Smith, the dulled intellect and depreciated vitality demanded a colder compress and more brief application. Dr. D. told me after his recovery that the compress had aroused him from stupor and that he did not remember my having been summoned to him.

3. *Excretions.*—Roque and Weil have shown that in infectious fevers the urotoxic coefficient is increased fivefold by cold baths and this was confirmed by Hewetson of Johns Hopkins Hospital. That there is an enormous increase in the quantity of urine (from 100 to 150 per cent., ranging from 70 to 110 ounces) when small quantities of ice water are used in connection with the regular cold chest compresses is easily demonstrated. If the measurements had not been made by trained nurses they would be incredible. It will be readily seen that the rationale, which explains the action of cold moving air in pneumonia cases is the same as that of the cold wet compress. It may be noted, however, that peripheral excitation from the cold compress acts upon a vastly larger surface and is enhanced by its intermittence.

4. *Elevated Temperature.*—It was well said by one of the authors quoted that an ordinary rise of temperature does not require treatment. The chest compress at 60° F. has served me well in maintaining a safe temperature. Its antithermic effect may be considerably enhanced by permitting as large a quantity of water to remain in the linen as would not interfere with the patient's comfort by dripping and chilling. In this manner more heat is abstracted and more water is evaporated by capillary attraction through the meshes of the flannel cover.

Fig. 2.—The chest compress complete.

5. *Phagocytosis.*—Experiments made by myself in the Hydriatic Institute and by the house staff

of the Montefiore Hospital have demonstrated that cold applications to the large skin surfaces increases the number of white cells in blood drawn from the lobe of the ear, showing that they have been driven from stagnant points into the circulatory current where their phagocytic action may become more effective.

Hektoen concludes a recent able article, "That the leucocytes constitute an integral factor in the defensive mechanism of the body against the pneumococcus must be accepted as settled. Their behavior with regard to crisis is significant. The acme as well as the number of leucocytes in pneumonia appears to bear such relation to the crisis that it is logical to assume that they are directly concerned in its production." Long ago Winternitz claimed, on clinical grounds, that the value of cold procedures in all infectious fevers was enhanced by their effect upon increase of leucocytes.

Reduction of Mortality.

This outline of management of pneumonia patients represents a practice of thirty years. When I compare its clinical result in saving life, enhancing comfort to the patients, nurses, and myself, I am impelled to urge upon you its adoption. True, one must adopt his own ideas and not follow blindly the dictum of any one in medicine, but when remedial agents are explained upon a scientific rationale and the results are far more favorable than they are under apparently similar but not systematic execution of the method, it would not be unreasonable to expect similar favorable results from judicious application of the same method.

What is the clinical proof? After all this is the crucial test. The results in private practice are usually not recorded except in the mortuary statistics of the registrar. I may say, however, that the latter will show but two death certificates from pneumonia written by myself in the twenty years before I relinquished general practice, one being an elderly alcoholic and the other a woman seen on the third day of her illness with a temperature of 105° F. and almost collapsed from the effect of enormous self-prescribed doses of Epsom salts.

Of the number of cases I have treated while in general practice there is no record, but I may safely claim an average of five per annum.

Hospital statistics, on the other hand, are not a fair test of therapeutic value, because most cases enter several days after beginning of attack and have received medication usually; others are almost in articulo mortis. Nevertheless, a comparative test may be made between the statistics of hospitals. While visiting physician to the Manhattan General, now Knickerbocker Hospital, a search of the records revealed the fact that before the general adoption of the wet compress the mortality from pneumonia was 66 per cent.; after its adoption 156 cases showed a mortality of 33 per cent., while in the cases living till the fifth day the mortality was 12 per cent. When the fact is considered that these patients come from the lower types of tenements, Italian, Irish, and American, most of them habitual consumers of alcohol or actual drunkards, the result may be regarded as favorable. Compared with the 61 per cent. mortality reported in one of the articles quoted, this record is encouraging and points to far better achievement in private practice. Confirmation of my claim is found in reports by two military surgeons who used practically the same method. Staff Surgeon Schichhold of Dresden records in the *Medizinische Klinik* for 1906 a series of 200 cases of pneumonia among young soldiers with a mortality of three. Dr. Nepor, an Austrian army surgeon, reports 90 cases with a mortality of one.

That the management here outlined is also valuable in desperate cases is evidenced by four cases I happen to remember. One, Mrs. Du B., seen in consultation with Dr. E. H. Rodgers, a diabetic woman of 65, with grip pneumonia, and acetonuria; the others were colleagues who had been under skillful and sympathetic care of friends. Dr. J. H. D. seen with Dr. W. A. Ewing, Dr. X. with the late Dr. Palmer Cole, who published the case in the *Medical News*, the third Dr. B. seen with Dr. A. Herff of San Antonio, Texas, where I happened to be sojourning on my way to California. All had received the conventional treatment without result until the wet compress was applied in accordance with the indications presented by each case.

That judicious systematic management of the pneumonia patient will change the prognosis of pneumonia as surely as it has changed the prognosis of typhoid fever I doubt not in the least. To hasten this consummation I have presented to you such a method, the result of observation of half a century. Do not adopt it if it does not appeal to your judgment as rational and safe. But if the method *does* satisfy your judgment, after approaching it without bias do not attempt to modify it, for you will surely fail as have those whom I have quoted in the effort to improve upon the fresh air and water treatments that have been worked out with infinite care by their propagandists. One of these innovators has furnished statistics showing a mortality of 61 per cent. What the other innovators may have shown may be judged by the irrational methods they advise.

The principal lesson presented by these articles is that pernicious activity in giving food, air, water, drugs, and hydrotherapy has resulted in almost as large mortality in this "enlightened" age as was common in the past centuries of antiphlogistic battling against pneumonia.

51 West Seventieth Street.

PROGRESSIVE LENTICULAR DEGENERATION.*

By CHARLES EDWARD NAMMACK, M.D., L.L.D.

NEW YORK.

VISITING PHYSICIAN TO BELLEVUE AND TO ST. VINCENT'S HOSPITALS; PROFESSOR OF CLINICAL MEDICINE, CORNELL UNIVERSITY MEDICAL COLLEGE.

Since the comprehensive article by S. A. Kinnier Wilson (*Brain*, Vol. 34, Part 4, March, 1912) the attention of neurologists has been directed to this somewhat rare clinical condition. Wilson's monograph to which was awarded a gold medal by the University of Edinburgh, July, 1911, leaves little to be said, but it seems desirable to present and put on record the cases observed since then. James E. H. Sawyer (*Brain*, Vol. 35, Part 3, February, 1913) recorded a case which differed from Wilson's type in the absence of cirrhosis of the liver, which Wilson is inclined to insist upon as a necessary accompaniment of the condition, and also in having a longer duration than any of Wilson's twelve published cases. Since Sawyer's case, others have presented cases before neurological societies in this

*Patient presented before the Society of Bellevue Hospital Alumni, November 4, 1914, and before the joint meeting of the New York Neurological Society and the Section on Neurology and Psychiatry of the New York Academy of Medicine, November 10, 1914.

country which cases have been briefly mentioned in the published transactions of such bodies. E. Murray Auer (*Journal of Nervous and Mental Diseases*, Vol. 41, No. 6, June, 1914) has recorded a case occurring in the Kalamazoo State Hospital.

Fig. 1.—Patient braced at rest.

Williams B. Cadwalader (*Journal of the American Medical Association*, Vol. 63, No. 16, October 17, 1914) describes two cases from the Orthopedic Hospital and Infirmary of Nervous Diseases in the services of Drs. S. Weir Mitchell and John K. Mitchell, in neither of which cases was there any clinical evidence of the presence of hepatic disease. With this exception, all of the cases reported, including the one whose history follows herewith, and who was admitted to the Fourth Medical Division of Bellevue Hospital on June 20, 1914, correspond very closely to the condition first described by Wilson in his brilliant paper. Wilson's definition of the disease describes the characteristic features. It is "based upon pathological data, but at the same time is non-committal, as it entails no acceptance of a particular hypothesis as to the actual nature of the disease." He says: "Progressive lenticular degeneration may be defined as a disease which occurs in young people, which is often familial but not congenital or hereditary; it is essentially and chiefly a disease of the extrapyramidal motor system and is characterized by involuntary movements, usually of the nature of tremor, dysarthria, dysphagia, muscular weakness, spasticity, and contractures with progressive emaciation; with these may be associated emotionalism and certain symptoms of a mental nature. It is progressive, and after a longer or shorter period, fatal. Pathologically it is characterized predominantly by bilateral degeneration of the lenticular nucleus, and in addition cirrhosis of the liver is constantly found, the latter morbid condition rarely, if ever, giving rise to symptoms during the life of the patient." Wilson thinks the disease is important not only because of its rarity but because of the light it sheds on such diseases as paralysis agitans.

The symptomatology of the disease is well illustrated by the history of our Bellevue case, comprising as it does nearly all of the features embraced by Wilson's definition. The spasticity in our patient has not yet reached the extreme degree noted in Wilson's cases or in Sawyer's case. The dysarthria partakes more of a slurring element than of the staccato speech of disseminated sclerosis. There are other points of resemblance between progressive lenticular degeneration and dissemination sclerosis, but the preserved abdominal reflexes with absence of Babinski reflex and of ankle clonus will usually decide. In addition the rigidity of disseminated sclerosis is rarely so universal and contractures are not so essential a feature of its symptomatology. Pseudobulbar paralysis may present dysarthria, dysphagia, inability to protrude the tongue, paralysis of the palate, paralysis of the lower part of the face, sialorrhea, and often involuntary laughter, because the fibers of the pyramidal tract affected in pseudobulbar paralysis skirt the lenticular nucleus. But in progressive lenticular degeneration the palate and tongue are only apparently paralyzed. The palate moves on phonation. The tongue can be protruded. The dysarthria and dysphagia are the result of the rigidity of the motor mechanisms concerned. Paralysis agitans in several ways closely resembles progressive lenticular degeneration, but is easily differentiated clinically, although it may be analogous pathologically.

The prognosis of progressive lenticular degeneration is invariably fatal. The course of three acute cases averaged eight months and of eight chronic cases averaged four years in Wilson's reports. Sawyer's case had existed seventeen years when reported and "may live many years longer." Auer's case gives a history going back to 1898. One of

Fig. 2.—Patient about to walk.

Cadwalader's cases began at 14, and patient was eighteen when recorded; the other began in 1892 when patient was sixteen years old, was progressive at first, but became stationary after five or six years. Our Bellevue case began at the patient's

fifth year, fifteen years ago, and is non-progressive, except for his talipes equinovarus, which is rendering him steadily more helpless.

In the absence of a knowledge of the nature of the disease, the treatment is empirically symptomatic and palliative. The older writers, in the pre-Wassermann days, suspected hereditary syphilis, but in all the recent cases, including our own, the Wassermann reaction has been negative. Although more than one case has occurred in the same family in two instances, it seems certain that the disease is not due to a congenital or abiotrophic defect, as there is nothing *essentially* familial about the disease. Certain facts suggest some toxi-infective condition which has a predilection for youth, but there are no facts to suggest that this toxin is syphilitic. Wilson thinks that this toxin may be elaborated in the liver and may have a specific action on the lenticular nucleus, similar to the action of the poison in icterus gravis neonatorum.

Case.—R. S., age, 20 years, was admitted June 20, 1914 to the Fourth Medical Division. Occupation none.

Family History: Father died at age of 42 of glandular tuberculosis. Mother died at about same age of pulmonary tuberculosis. Father and mother were not consanguineously related. Mother had 7 children; patient is the last child. Four living and three dead. Those that are living now are in good health. Sister who is married is 21 years of age. Sister who is single is 24 years of age. Brother who is single is 26 years of age. One brother died of pulmonary tuberculosis. Cause of others' deaths: (1) malignant diphtheria; (2) 13 months old, cause unknown. Patient states that as far as he knows no one in his father's or mother's family had a condition similar to his. Negative family history of gout, rheumatism, syphilis, alcoholism, nervous affections. The married brother has one child who is at present in best of health. The married sister has two children who are fairly well.

Previous history: Occupation—Patient went to school, until he was unable to stay in class. Habits: Smoked cigarettes, and drank a glass of beer at times. Drinks tea and coffee. Ate meals irregularly. Would eat double meals. Bowels always regular. Likes sweets, as candy and sweet fruits. Had the usual diseases of childhood; at 5 years of age lost speech and power of walking, being obliged to creep around, but was able to start to school at age of 10, and finished at age of 16, in 4-a grade. Had scarlet fever at age of 6. Patient states that he was very good in school; was always near the head of his class, and liked to study very much. He could learn his lessons very well but was lazy and tired during the morning hours. Had a bad temper and would get into quarrels and scraps with the other boys. Left school at age of 16 because the left arm began to shake. The hand shook so badly that patient could not hold whatever he had in his left hand. The tremor was first noticed while patient was writing. Had to hold his hand against his body to prevent the tremors. Treated at dispensary about his 10th year without diagnosis; treated at a college clinic between 12th and 13th year; diagnosis withheld. After patient left school he stayed home; would go out with dray men, etc., for pleasure. Has never worked any or made any money. Has no trade.

Present history: The first symptoms of the disease occurred at age of 5, before patient was in school. Noticed that his left hand trembled considerably and right leg slowly turned in, as patient expresses it. The foot finally got in such a condition that he was walking on the side of the foot and so he had to catch hold of bed-posts, etc., to support himself. None of the doctors knew what this condition was. His family physician said that he had St. Vitus' dance. Patient can write if he keeps the left arm away from the paper. Patient states that he has never fallen to sleep in the bathroom, etc. States that he used to get dizzy but would not faint. Says that his speech was worse than now while he was going to school. There is no history of patient having a fit or becoming unconscious previously or at present. The hand began to shake more and the foot condition became worse, speech becoming more nasal. When he starts to do anything he has to wait a few seconds and then gets up quickly and off his chair. Then it would take him a few seconds to move. As soon as he got up he would start swaying around and would have to hold on to the banisters, etc., and pull himself along. If he was in the open and nothing to pull with, then he would throw himself forward and drag or slide his feet. After he got started walking he could walk a good deal, unless he stopped. Says that he could walk across Brooklyn Bridge providing he did not stop, but kept right on. Patient has remarkably developed muscles of trunk and arm. Three years ago patient would walk backwards for a few blocks; was afraid to walk frontways as balance was better in retropulsion. Says that his temper became worse and that he would quarrel with his sisters, etc. Would strike them, that is, he would grab and hold them until he was able to strike them. The movements of hand took so long that sometimes he would be unable to strike them. Patient's facial expression is fixed; mouth large and drawn, and when walking or doing any form of exercise he protrudes tongue and draws mouth. Patient understands everything that is said to him and is in a jolly mood. He enjoys laughter and funny books. Seems to have the intelligence of a boy 12-13 years old. When the patient smiles it comes slowly and remains longer than average in the normal person. Patient's condition has not changed, he says, only that he is losing control of right leg. His condition never was so bad that he had to be undressed and put to bed; could feed himself and dress himself, only it would take him longer. Says that he must eat slowly.

Patient has been in hospital since June 20; does not seem to differ physically or intellectually since the date of admission. His movements were jerky; that is, his head and arms would jerk while his spine becomes rigid. Talipes equina varus of left foot. He bends forward, the right foot is thrown out into an inverted position and left leg is drawn by sliding; in the mean time the head, arms and pelvis go through jerky motions. The speech long and drawn out; few words understood; swallowing normal. Appetite good. The tremor of the hand coarse. The grip in the hands is very good. Knee jerk and ankle jerk exaggerated when patient entered hospital, also the same as the present time. Sensations appear to be normal.

General appearance: Patient is a well developed and nourished male about 5 feet 5 inches in height; weighs 132 pounds. The difference between the flat facial expression with his quick and shrewd eye is very noticeable. Has continuous jerks of head and left arm. Mouth large and elongated. Head: Considerable amount of red hair on head; circumference 56 cm. The face is very wanting in expression; flat, vacant and serious, rather than silly. When patient smiles the smile broadens out and gradually fades away. Continues to have the good tempered look; no depression. Takes great interest in passing events, especially the war. Reads the papers fairly well. Eyes: Pupils dilated; react to light and accommodation. Has a small jerky nystagmus laterally. Other extrinsic ocular movements negative. No ptosis, strabismus, diplopia, hemiopia, etc. The sclera are clear. Conjunctiva not congested; no exopthalmus or Von Gräfe's sign. Corneal reflexes abolished. Discs are normal. Face: The mouth is opened slowly. When patient is walking or doing any form of exercise the mouth is drawn to the right side of face and tongue protrudes. Mouth is continuously kept open; no dribbling of saliva. The face is flat, mandible protrudes farther outward than the rest of the face. Has a pretty good growth of hair on face. Speech: Is dysarthric. It is impossible to understand some of the words spoken. They are drawn out in slow syllables. Patient continuously grunts. Teeth: In poor condition with very marked pyorrhea. No cavities. Tongue: Red and fine tremors on edge; coarse elsewhere. Throat: Negative; reflex abolished. Nose: Negative. Sinuses: No tenderness. Ears: No discharge: hearing is normal. Taste: Patient can tell sweet from sour, and call the constituents of ingesta.

Chest: Expansion of lungs good; anterior curvature of the spine. Heart: Apex is in 5th inner space, 12 cm. from M. S. L. Left border is 13 cm. from M. S. L. in 3rd space. In 5th space it is 12 cm., M. S L. Right border of heart, 4 cm. to the right of M. S. L. in 3rd space. Sounds at apex; presystolic murmur ending in a sharp crescendo of first sound and systolic murmur which is transmitted to axilla. The systolic murmur at apex is transmitted to pulmonic area also. A purring thrill is felt at anex. Apex bounds against the chest wall, a heaving like character. Lungs: Palpation, percussion, auscultation negative. Abdomen: No

tenderness, rigidity, palpable tumor, or visible peristalsis. No scars; no distention. Liver: Not palpable. No evidence of cirrhosis. Spleen: Not palpable. Kidneys: Not palpable. Skin: The skin is dry and well colored. No edema or eruptions. Muscles: The muscles of right leg are not very well developed. The muscles of left leg compensate by remarkable development. Muscles of chest and arm are developed, especially biceps. Bones and joints: Talipes equina varus with inversion and rotation of right ankle. Atrophy of muscles around right hip. Left arm spastic. Lymphnodes: Postcervical and epitrochoel glands enlarged. Reflexes: Knee jerks, right and left, exaggerated. Ankle jerks exaggerated. Wrist jerks present; elbow jerks present. Abdominal reflex exaggerated, right and left; both cremasteric reflexes exaggerated. Negative Babinski on right. Babinski on left is doubtful. Negative Oppenheim on both sides. Negative ankle clonus on both sides. Speech: Dysarthria. Hearing: Good. No tinnitus or discharge. Sensations: Pain negative. Pain sense normal, no retardation. Temperature: Heat and cold normal. Taste: Good for sweets and bitters. Smell: Good. Position: Good. Orientation: Place, person, time, events, present and past conditions, good. Stereognosis and diadokokinesis good. Atrophy: There is atrophy of muscles of right leg, hip, and calf. Compensatory hypertrophy of the other muscles of the body. Wassermann test: Negative on repeated examinations.

42 East Twenty-ninth Street.

DYSTONIA MUSCULORUM DEFORMANS;*

WITH REPORT OF A CASE.

By H CLIMENKO, M.D.,

NEW YORK.

INSTRUCTOR IN NEUROLOGY AT THE NEW YORK POST-GRADUATE MEDICAL SCHOOL; ADJUNCT NEUROLOGIST TO THE MONTEFIORE HOME AND HOSPITAL, AND CENTRAL AND NEUROLOGICAL HOSPITAL, BLACKWELL'S ISLAND.

In 1911 Oppenheim reported a group of cases in which he described a peculiar syndrome and named it "dystonia musculorum deformans." Somewhat earlier than Oppenheim, Ziehen and also Schwalbe described similar cases, but the former named the syndrome "tonic torsion neurosis," while the latter called it "general tic with tonic changes." A survey of the cases shows that they all come under the same category, and after a careful analysis we must admit that the name adopted by Oppenheim is the most suitable. Joseph Fraenkel, however, who in 1912 also reported a group of cases, termed this disease "tortipelvis" and placed it in the class of spasmophilia. The name is correct if Fraenkel's view on the etiology is accepted. He considers it the result of a defect in calcium metabolism and holds the parathyroids responsible for the disease. Flatau and Sterling furnished a further contribution to the etiology of this disease. They have described two cases under the heading of "progressive torsion spasm in childhood." Cases of dystonia were also reported by Abrahamson, Spiller and Belling. Almost every writer attaches a different name to the disease, influenced probably by his etiological interpretation. With a few modifications, however, they all agree on the presentation of the clinical manifestations of the disease.

Dystonia musculorum deformans is a chronic, progressive disease occurring mainly in later childhood. The chief characteristic is a partial or total loss of functon in one or more extremities, preeminently the lower. The loss of function is due to an improper tonus innervation. In consequence of this, we have forced, involutary, bizarret, and riotous movement. These various forms of movement give a characteristic feature to the disease. The cases so far reported were only among Russian or Galician Jews. Both sexes are about equally represented. So far as our present observation goes,

Fig. 1

heredity seems not to be a factor. The onset is gradual and the affection is steadily progressive.

Fig. 2

As a rule the initial symptom is a subjective weakness in one extremity, usually a lower. A few months later the other lower becomes involved and the patient is unable to stand or walk. A peculiar form of astasia abasia develops; indeed, due to this

*Read at a joint meeting of the New York Neurological Society and the Neurological Section of the Academy of Medicine, November 10, 1914.

peculiarity, the disease was mistaken for hysteria. The gait is quite characteristic and one that cannot be found in other forms of disordered locomotion resulting from a diseased nervous system. The patient bends his body forward, the trunk is twisted

Fig. 3

on the pelvis; thus the buttocks are distorted with torsion-like movements. With one hand he grasps the corresponding, or opposite, extremity and in this position makes a few irregular and improperly controlled steps. He soon tires and falls. Each step is accompanied by a number of dyskinetic and unskilled movements of the extremities involved. The movements are spasmodic and jerky; they resemble athetoid movements, but lack the characteristic marks of athetosis. The movements are not under the control of the will; the more the patient endeavors to overcome them the more pronounced they appear. They diminish when the patient is in repose but disappear only in sleep. This gait, when seen once, cannot be mistaken.

Further observation reveals a peculiar tonus in the muscles which is pathognomonic of the dis-

Fig. 4

ease. In the same extremities and at the same time there are commonly found one or more muscles in a state of tonic contraction while another muscle or group of muscles are entirely relaxed or hypotonic. Indeed, there is a peculiar play of hypo- and hypertonicity to be recognized by the sight and touch of the observer. So far, no other affection of the nervous system shows these peculiar conditions. The tendon reflexes are exaggerated or diminished or even absent according to the tonic state of the muscles concerned in the reflex in question. The Babinski sign is absent, nor is there present any symptom except the disturbed tonus that would point to an organic involvement. While almost the entire musculature of all the extremities and trunk may become involved, the face usually escapes. The resulting deformities, such as the twisting of the pelvis, scoliosis, and lordosis, disappear in the recumbent posture. The talipes valgus and varus are somewhat permanent. The psyche is clear. Spiller's case forms an exception.

After observing a case and after studying the literature with care, one cannot help feel that we are dealing here not with a functional but with an organic disease. It is true that the pathogenesis is only a matter of conjecture. Of all the various theories advanced, only two are worthy of consideration. One, advanced by Joseph Fraenkel, considers the disease to be a sequel to a selective poison resulting from faulty metabolism, *i. e.* a calcium deficiency. *X*-ray pictures taken of our case show some abnormalities in bone formation. This, apparently, might tend to substantiate Fraenkel's view. We, however, undertook to make a study of the calcium metabolism in this case and not until it is completed can we offer any interpretation of these abnormalities, nor have we enough facts to speak pro or contra Fraenkel's view.

The other theory is that of Oppenheim, who

Fig. 5

thinks we are dealing with a degeneration of special systems that govern the tonicity of the musculature. The theory advanced by Flatau and Sterling that we are dealing with a special type of athetosis, I believe can be completely dismissed.

I therefore believe that Oppenheim's terminology can temporarily be accepted and the disease named dystonia musculorum deformans. There is another important feature that I would emphasize: the disease, although recently described, is doubtless not new. It was probably diagnosed as hysteria and considered as such. It would therefore be interesting to study the autopsy findings in cases of so called hysteria in which allied clinical manifestations were observed with a view of associating these cases with a possible pathology of dystonia musculorum deformans.

CASE.—S. P., a girl 11 years old, of Jewish parentage, born in Russia, was admitted to the Montefiore Home on September 27, 1914, with the following history: Father is 43 years old; does not use alcohol; smokes moderately. At 28 he had an attack of acute articular rheumatism. Denies any venereal infection. Mother is healthy; had one miscarriage and four children at full term, three of whom are in good health. S. P. is the third child; was born at full term; perfectly normal labor; was breast fed. Began to walk and talk at about 1½ years; first tooth at 5 months; had German measles at 2 years; at 3 years had two attacks of tonsilitis; at 9½ years had an attack of whooping cough. Bowels always irregular; appetite poor; sleep frequently restless. Played a good deal outdoors. Was bright at school. About a week or two after the attack of whooping cough, *i.e.* about 18 months previous to her entrance to the Montefiore Home, she began to complain of weakness in her left lower leg. A little later she noticed that the foot turned outward while running or in quick walking. The weakness traveled upward and her left knee gave way. Plaster of Paris was applied to the knee joint which seemed to relieve her a great deal. A few weeks after the onset she began to complain of weakness in the other leg and soon the left hand became involved; with each attempt to use the hand it began to tremble. Similar tremors were observed in the lower extremities. She complained of no pain nor parasthesias of any kind. The condition progressed steadily.

About a year after onset the patient was no longer able to walk. Her chief complaints at present are (1) inability to walk, (2) weakness of right upper extremity, (3) trembling of all extremities. In the recumbent posture patient shows a slight wormlike tremor of all extremities, more pronounced on the right side. In a position of rest with extremities as nearly in repose as possible, a movement, better appreciated by touch than by sight, is constantly present. It somewhat resembles athetosis but lacks all the characteristics of that movement; it seems to possess a characteristic of its own being somewhat irregular, wormlike, and entirely lacking in rhythm. It partakes really of the wormlike movements characteristic of the muscular movements in this patient; perhaps the word dyskinesia might be most appropriately given. In the prone position there seems to be a characteristic pose consisting of flexion of the right knee with extension and external rotation of right hip and outer rotation of left foot. There is a slight kyphosis in the lumbar region of the spinal column; this becomes more pronounced in the sitting posture.

On standing (see Figs. 1 and 5) a kyphoscoliosis is equally pronounced. The trunk assumes an acute angle with the pelvis, the latter varying in its position with movement. The patient can stand only with support. On standing, the right foot is at an unusual angle with th loewer leg; the inner sole is raised. Due to extreme hypotonia the right knee assumes almost the shane of a genu recurvatum. The patient is unable to walk unsupported, a marked feature being a peculiar torsion of the trunk on the pelvis, the latter being thrown out of a normal angle relation with the trunk. In trying to walk, there are numerous riotous, unskillful and disharmonious movements through the extremities and trunk; to correct these, the patient seizes her left lower extremity (see Fig. 2) at the joint, forcing it into proper position; she thus expends an inordinate amount of energy in attempting with her hands to facilitate locomotion, alternately pressing back one knee, then the other, as the obstreperous joint gives way under the body weight. The right hamstring muscles are in a state of hypertonicity, almost rigidity; the muscles of both legs are also in a state of hypertonicity. Both quadriceps groups and the left peroneal group are on the contrary almost in a state of complete atonia. The hips are hyperflexed (see Fig. 3) on the abdomen. Due to the atony of the flexors digitorum of the right hand, the fingers can be hyperextended to such a degree that on dorsal flexion (really extension) of the fingers, they can be brought to an acute angle with the dorsum of the hand. (See Fig. 4.) Both knee jerks are diminished; ankle jerks are obtained with difficulty. Babinski and Oppenheim signs are absent. Abdominal reflexes are present. All the various sensibilities are intact. Cranial nerves are normal. She shows adenoid facies. Heart, lungs, and abdominal viscera reveal no abnormalities. Patient is able to write with difficulty. Electrical reactions show no qualitative changes. A hyperexcitability, however, is obtained in the hypertonic muscles. Urine shows a slight excess of indican; otherwise negative. The psyche is perfect. *X*-ray report shows: neck of left femur abnormally short and thickened. The trochanter major on the same side also presents an abnormal configuration. The bone structure, however, appears normal. Dorsal and lumbar spine shows no abnormality. The sacrum, however, appears twisted, giving the entire pelvis a tilted position.

252 EAST BROADWAY.

EXTRAPYRAMIDAL HEMIPLEGIA.*

BY ALFRED GORDON, M.D.,

PHILADELPHIA, PA.

THE new clinical type presented in the following case is of interest from a physiological standpoint as well as from the standpoint of localization. It differs from the commonly known form of cerebral hemiplegia in many essentials and yet it may be taken for the latter if care is not exercised in the discrimination and interpretation of each individual manifestation. A very attentive investigation of all hemiplegic cases will perhaps reveal a greater frequency of this type of cases. In the literature at my disposal I have failed to discover identical records.

Patient, male, twenty-five years of age, Austrian by birth, had typhoid fever at the age of eight. Before the temperature began to fall he had an apoplectic seizure with loss of consciousness. He became hemiplegic on the left side and aphasic. The aphasia lasted several months. The hemiplegia remained. A year later he developed ataxic movements of the left arm and contracture of the fingers of the same hand. When he came under my observation last May he presented the following condition, which has remained unaltered up to the present time.

There is apparently a left hemiplegia with the face drawn somewhat to the left. His gait, however, is similar to that of hemiplegics: the patient drags his left leg and scrapes the floor with the left foot which is kept in a state of marked contracture. The only difference is found in the bending of the body while walking toward the affected side instead of toward the normal side, which is the case in the classical hemiplegia.

There is no distinct rigidity of various segments of the left arm and leg, as on passive movements resistance is easily and promptly overcome. Indeed at times hypotonia is observed. In fact there is not much paralysis, as voluntarily he can move every joint except the wrist and ankle. The hand is always in a state of extreme contracture. The fingers are tightly closed on the palm. The least attempt to unfold them increases the contracture. The shoulder and left arm present involuntary movements. The arm always moves away from the trunk. When the patient abducts the arm voluntarily the latter becomes everted and the contracture of the fingers is then extreme. When at rest involuntary contractions are also observed in the left side of the face, especially in its upper half. The contractions are more marked on passive or voluntary movements. Then not only the muscles of the left side but also the muscles of the neck and the lobe of the left ear are animated with movements. The latter is particularly noticeable on voluntary movements. The muscular contractions are rhythmical in character. The same phenomenon is observed in the left foot when the patient is undressed. The toes and the muscles of the entire foot

*Patient exhibited before the Phila. Neurological Society, October 23, 1914.

become contracted the moment one attempts to move them. This is noticeable when the patient lies on his back or sits with his foot on a chair. The movements are slow and regular. It is also interesting to note that associated movements are observed on the entire left side, including neck and face, whenever a passive movement is brought on in any portion of the left side. The face presents this peculiarity that the muscles on the left seem to be somewhat thin, perhaps atrophied, although no reactions of degeneration are observed. The left musculus frontalis does not contract when the patient is told to raise his brows or wrinkle the forehead. There was evidently a palsy at the time of the hemiplegia. When the patient talks or smiles the mouth is drawn toward the left and the facial folds are deeper on the left than on the right. However, when he is told to move his lips to either side he does it about equally well on both sides. The tongue protrudes in the median line and no involvement of it is noticed. The pupils are somewhat large but equal and react promptly to light

Extrapyramidal Hemiplegia. Wrist, fingers, and ankle are seen in extreme contracture when patient attempted to move his arm. Atrophy of left side of face.

and accommodation. The eyegrounds are normal. The speech is normal.

The patellar tendon reflexes are markedly increased, more on the left than on the right side. There is no ankle clonus, no Babinski, no Oppenheim, and no paradoxical reflex on either side. The abdominal and cremasteric reflexes are preserved on both sides. The epigastric reflex is diminished on the left.

Sensations to touch, pain, and temperature are all normal and equal on both sides of the body, including the neck and face.

When undressed the patient presents a distinct curvature of the trunk with the convexity of the spine toward the right side. The body is inclined to the left side when he is standing or walking. The muscles of the left side of the trunk, including the buttock, appear flattened and somewhat atrophied. The muscles over the scapula, thorax (anterior and posterior views), the clavicular region, the neck, face, and forehead appear thin and undeveloped. The same condition, although not so marked, is observed in the left lower limb.

The man complains of no pain nor of any other physical disturbance except of frequent attacks of exhaustion, which last from a few days to two weeks. All vegetative functions are normal, the sphincters are not disturbed. The mentality is normal.

Uranalysis, blood examination, and Wassermann test of serum are all negative. Thoracic and abdominal viscera are intact.

Comment.—In discussing the diagnosis of the case several possibilities are to be considered.

First of all organic hemiplegia. The onset of the condition, viz., in the course of an infectious disease, suddenness of the attack with total loss of consciousness and subsequently paralysis on one side with aphasia, are all in favor of an organic lesion in the opposite hemisphere. On the other hand, the absence of the marked contractures in the joints of the arm and leg in spite of the long standing of the condition, the absence of the characteristic resistance on passive motions, the presence of hypotonia which is sometimes observed, the absence of actual paralysis, the absence of ankle clonus and especially the absence of the toe phenomenon, the preservation of the abdominal reflex, the inclination of the trunk toward the affected side in walking instead of toward the unaffected side, all these features speak against the classical localization of the lesion in cases of organic hemiplegia, viz., in the internal capsule. Besides, the atrophic condition of the musculature of the left side of the face, the involvement of the left frontal muscle, the associated muscular contractions of the left face and of the left ear upon the least passive movement of the arm or leg, the peculiar eversion of the left arm on movements, the extreme contracture of the fingers of the left hand especially on motion (passive or voluntary), similar rhythmical movements of the left foot, distinct curvature of the trunk toward the affected side, all these peculiarities are not met with in the classical type of organic hemiplegia.

Another possibility to be thought of is hysteria. First of all, the onset of the hemiplegia without a preceding emotional element, the profound loss of consciousness which accompanied the apoplectic insult, the aphasia (not mutism) lasting several months, the total loss of power in the left side during a period of several weeks, all these symptoms speak against hysterical paralysis. In the next place the present condition of the hemiplegia, viz., total freedom from sensory disturbances on the paralyzed side, absence of any of the well-known hysterical stigmata in the sensorimotor sphere, also in the domain of special sensations, the deviation of the face and the involvement of the frontal muscle on one side, the atrophic condition of the musculature on the face, the extreme state of contracture of the left fingers, all these features are not found in hysterical paralysis. Moreover, the characteristic feeling of increasing voluntary resistance experienced by the hand of the observer in attempting to flex or extend a limb affected by a palsy of a functional nature is not present in this case. Finally, the existence of paralysis of this nature for seventeen years is quite unusual in hysteria.

When standing the patient resembles somewhat Oppenheim's cases affected with *Dystonia musculorum deformans*. In both cases we find a deformity consisting of a marked lordosis of the dorsolumbar region with a lateral inclination of the pelvis. But here ends the resemblance. In my case we do not find the twitchings in the muscle of the pelvic girdle and quadruped-like gait with

the clownish movements; the knee-jerks, on the contrary, are here increased and a paralytic condition on one side is present.

Finally, my case has some points in common with S. A. K. Wilson's "Lenticular Degeneration" syndrome with this difference that the symptoms are confined to one side. We find here very little paralysis on the affected side; spasticity of the hand, which is very pronounced; muscular contractions which increase with movements; preservation of abdominal reflexes; finally, and very emphatically, absence of toe phenomenon in spite of the spasticity of long standing. The latter circumstance especially speaks in favor of integrity of the pyramidal tract. As a hemiplegia actually occurred and it was of apoplectic nature, also as it developed in the course of an infectious disease, there can be no doubt of its organic nature. But in view of the clinical features uncommon to classical hemiplegias because of absence of true paralysis and particularly because of absence of the toe phenomenon, I am of the opinion that the lesion must have been in all probability not in the internal capsule, but "extrapyramidal." In view of a certain resemblance to Wilson's disease it is presumable that the lesion in my case is also in the corpus striatum, but only on one side. By analogy we may perhaps classify my case as an example of "Unilateral Extrapyramidal Degeneration." In view of the suddenness of onset with loss of consciousness the initial lesion was probably a hemorrhage. The following picture may, therefore, constitute a "unilateral extrapyramidal symptom-group."

A certain degree of loss of power on one side but not amounting to an actual hemiplegia; spasmodic contractions on the affected side brought on especially on movements (passive or active); absence of abnormal reflexes common to classical hemiplegias; preservation of the abdominal reflex; increased patellar tendon reflex; absence of sensory disturbances on the affected side; wasting of muscles on the same side. If the face is affected there are also associated spasmodic contractions of its muscles when movements are produced in the arm and leg. The mentality is intact and there are no disturbances referable to the eyes.

1812 Spruce Street.

COMPRESSION FRACTURE OF THE UPPER EXTREMITY OF THE TIBIA.

By A. C. BURNHAM, M.D.,

NEW YORK.

In 1886 Wagner[1] called attention to an unusual fracture of one or both tuberosities of the tibia which was caused by indirect violence. To this injury he gave the name of compression fracture, because it was apparently due to the pressure of the lower end of the femur upon the head of the tibia.

Eleven years earlier, Heydenreich[2] had collected from his personal experiences and the literature four cases of fracture of one tuberosity of the tibia but he believed that most of these cases were due to direct violence. More recently, Sonntag,[3] Erfurth,[4] Albers,[5] Wharton,[6] and others[7] have added additional cases.

The mechanism of compression fracture as given by Wagner is essentially as follows: The patient falls striking on the feet with the knees in extention and the force of gravity, acting through the femur on the tibia, drives the inferior surface of the internal condyle of the femur against the superior surface of the inner tuberosity of the tibia, the force of the impact breaking the tuberosity from the tibia. In the same manner, in patients having a moderate amount of genu valgum, or where the force of the impact acts obliquely tending to abduct the leg at the knee joint, the force acts through the external condyle of the femur and a fracture of the outer tuberosity of the tibia is the result.

Several of the reported cases have occurred in patients giving a history of a fall from a moving vehicle in which there was an element of rotary force caused by the body turning after the foot has struck the ground. In fractures of the outer condyle, the muscular force of the biceps acting upon the fibula and through it upon the tuberosity of the tibia, may exert enough traction to be an added element in the causation of the fracture.

X-ray photograph of right knee of patient, Mrs. M———, showing compression fracture of the external tuberosity with displacement outward.

Sonntag,[3] in 1906, collected 34 cases of compression fracture. In 24 of these a fall upon the feet was given as the cause. In one case a heavy weight falling upon the shoulders was the causative agent.

Albers,[5] in an interesting article published in 1894, reports four cases of compression fracture which were due to the accidental fall of an elevator. The fracture occurred in the leg supporting the larger part of the weight of the patient at the time of the accident.

There are a few cases in which the injury may be caused by forced adduction or abduction at the knee without an associated fall upon the feet. In these cases it is possible that the condyle of the femur is driven into the head of the tibia, which may be fractured before the powerful crucial ligaments of the knee are ruptured.

The bone usually is fractured anteroposteriorly through the articular surface, the line of fracture

usually occurring about midway between the attachment of the crucial ligaments and the lateral margin of the bone. The line of fracture then passes downward and to the side of the bone, emerging on the side of the tuberosity about two inches from the articular surface.

The lateral fragment in some cases may be in close approximation to the fractured surface, but it is usually displaced downward and laterally away from the fractured surface. When the external tuberosity is fractured the fibula usually is intact. However, a fracture of the fibula at a point an inch or more below the head may occur as an associated lesion. The joint, as is the case in most intra-articular fractures, becomes filled with blood and a condition of hemarthrosis results. Ordinarily, the lateral ligaments upon the opposite side are uninjured.

The symptoms of this injury are those of a severe trauma to the knee joint. The fracture itself may be overlooked, being most commonly mistaken for a rupture of the ligaments.

Meerwein[5] reports four cases in which the external tuberosity was fractured without marked displacement of the fragment. These patients were able to walk and the pain and disability were not such as to suggest fracture.

Solomon believes that in some cases a secondary fracture of the fibula occurs when the patient tries to walk on the injured leg. Ecchymosis is usually early and extensive. Crepitus and false point of motion are easily obtained if the type of fracture is borne in mind and the loose fragment grasped between the thumb and finger and moved upon the tibia. The joint is greatly swollen and there is increased lateral mobility of the knee in a direction away from the injured side, but, because of the preservation of the lateral ligament, the joint is firm when motion is attempted toward the fractured side. This is an important point in the differential diagnosis between compression fracture and the transverse fracture of the upper third of the tibia. In the absence of crepitus the injury may be diagnosed from rupture of the lateral ligaments by the point of local tenderness from $1\frac{1}{2}$ to $2\frac{1}{2}$ inches below the upper margin of the tuberosity.

Sonntag found that most cases occurred in adult males and that the internal tuberosity is most often affected. However, in a large proportion of the cases, the external tuberosity was fractured and Meerwein has shown that in three of his cases, in which the external tuberosity was fractured, there was a preexisting double genu valgum.

The prognosis for a complete return of function is poor. Partial loss of function is the rule, but a useful limb is usually obtained. There is usually a long period of complete disability followed by partial disability for months with permanent weakness and diminished function of the knee joint. A condition similar to chronic rheumatoid arthritis may occur months or years after the injury.

The treatment consists in the application of lateral splint or plaster cast to prevent the lateral mobility of the knee with passive motion and massage after an interval of from three to four weeks. The patients may be safely allowed up on crutches after four to six weeks in bed and they may attempt to walk by the end of the eighth week. It is usually several months later before they walk freely and the reported cases as a rule showed considerable disability on examination from one to two years after the accident.

Operation with the reduction of the fractured tuberosity and its fixation by nails or plates is theoretically dangerous because of the involvement of the knee joint and, while the results in the cases published have been unsatisfactory, with the modern technique the radical reduction of the fractures is the indicated method of treatment.

Involvement of the peroneal nerve in the callus may require operative interference (Wharton).

The following case was admitted to the hospital in November, 1913, and is presented as a representative case of this type of fracture:

Mrs. M.——, age 25 years. To escape from a fire, she jumped from the first story (about 12 feet) the night before admission. She was holding a two-year old child in her arms and struck on her feet on the stone pavement. Does not remember that she fell on one leg with any more force than the other. Was unable to walk because of severe pain referred to right knee.

Examination: Patient in marked shock with severe superficial burns and bruises about body. The right knee is markedly swollen and the patella floating high above its articular surface. There is considerable ecchymosis below and behind the external aspect of the joint and the leg appears to be slightly adducted at the knee. There is acute tenderness over the external tuberosity which can be freely moved on the tibia, motion being accompanied by distinct bony crepitus. Flexion and extension at the knee are painful but fairly free, evidently limited by the effusion in the joint. When abduction at the knee is attempted, the joint is firm but adduction may be accomplished to about 15 degrees. Examination of the fibula fails to demonstrate any injury.

Diagnosis: Compression fracture of the external tuberosity of the tibia associated with hemarthrosis.

An external lateral splint was applied and the patient sent to the *x*-ray room for examination. The plate showed an oblique fracture of the external tuberosity with displacement of the fracture backward and outward. (See accompanying illustration.) Three days later the fragment was manipulated in the attempt to reduce it and a circular plaster bandage applied from the ankle to the groin, the leg being held in forced adduction, thus making the internal lateral ligament tense. Cast remained on for three weeks after which it was removed at intervals for passive motion and massage.

Convalescence was slow and it was over twelve weeks before the patient was able to walk with crutches. Six months after the accident she was able to walk with a cane but still had some lateral mobility at the knee joint and flexion at the knee was possible through an angle of only about 45 degrees. There was still some swelling of the knee.

In this case the following points were demonstrated:

1. The possibility of diagnosing this type of fracture from the history and the examination even in the absence of the *x*-ray.
2. The long duration of the swelling about the knee.
3. The prolonged convalescence and probable permanent disability of the knee joint.

THE DIATHERMIC TREATMENT.

By A. D. ROCKWELL, M.D.,

FLUSHING, N. Y.

NEUROLOGIST AND ELECTRO-THERAPEUTIST EMERITUS TO THE FLUSHING HOSPITAL.

In the Medical Record of May 30, 1914, there is an article of mine, entitled "Observations, Based on Forty-five Years of Electrotherapeutic Work." Its chief object was to call renewed attention to the latest and most remarkable manifestation of electric force in its relation to medicine.

I allude to the high frequency current and more especially to its use by the diathermic method, and my desire in supplementing that article by this is not alone to emphasize its great and unique value in pathological conditions, but to show what a simple thing is its utilization. There is no reason why every general practitioner, as well as specialist, should not have it as an ever ready and practical aid in his office work. When we had at our command only the faradic and galvanic modalities, the busy practitioner found that he could not well utilize them to advantage. To say nothing of the time and active attention necessary, special skill was required to differentiate and get the best results, and altogether, the attempts were discouraging. Static apparatus, serviceable as it may be, takes up more room than many have to spare or care to give; and, to do justice to its varied and more or less complicated methods of administration, demands not a little study and active personal attention.

And so in this paper I desire to impress the fact of the greater simplicity of the diathermic applications of the high frequency current and to assert, at least, if I cannot demonstrate, how superior in general effect it is to every other manifestation of electricity.

Some time ago a well known foreign authority along this line got the ear and favor of the censor of cablegrams to our daily press; and in leaded lines appeared the announcement of something quite new as well as remarkable in the field of electrotherapeutics. Among other things, he could add a definite amount of calories of heat to the body, thus even lessening the amount of food necessary to sustain life, which, if true, would be a valuable economic resource.

His enthusiasm led him to claim various other astonishing results. It seems, however, that there was nothing at all new about the method of treatment itself. We in America had been using the same sort of thing for some time, and although we had not then and have not yet ventured to claim such extraordinary results, yet all there was to it was known here. And it is a wonderful thing to be able to add in this simple and delightful way to the heat of the body, and so to influence circulatory changes.

As the simplest illustration of its action watch its effects upon a person chilled by exposure to cold, or because of age, or some toxic effect. Absolutely without other sensation, a glow begins to pervade the entire system. Hands and feet become warm, the body perhaps uncomfortably so if the treatment is prolonged, and under the broad, flexible electrodes there is profuse perspiration.

Surely such prompt and profound constitutional effects must hold important relations to many constitutional conditions.

These results are familiar enough, of course, to those who are daily using this form of electricity, but to the great body of the profession they are not known, nor, I regret to say, do the members of the profession seem to care very much about knowing them. Its effects are not at all like the effects of radiated heat, or the heat imparted by the galvanic current.

Radiant heat reddens the surface and causes profound superficial congestion, and the galvanic current confines its effects mostly to the skin and the immediate underlying tissue; but the effects of these high frequency currents are diathermic, *through and through*, and the most positive influence is over the circulatory activities in the deep organs and tissues.

In the article alluded to I remarked that so much could be said therapeutically about the high frequency current that I should content myself with saying very little. What I said was solely along the broad general principles of its action.

Now, however, I am tempted to refer very briefly to just a few cases, to show what an aid it sometimes is in giving relief in conditions of rather uncertain or indefinite pathology, where ordinary methods have failed.

Case I.—The first case that I select is that of a man aged thirty-eight, who came to see me at the suggestion of Dr. David Webster. He was of rather stout build, very athletic, and in excellent general health, but for several years had suffered from frequent periodical attacks of severe pains through the eyes and frontal regions so that he was not infrequently compelled to neglect his work. Glasses and other methods failing to influence the symptoms, he experienced almost immediate relief from these diathermic applications. They were repeated two or three times a week through a period of two months, after which, for nearly a year, he was without a recurrence. Since then there have been two slight relapses, always followed, however, by quick relief through treatment.

Case II.—The second case is that of a lady aged fifty, who came to me with the concurrence of her physician, Dr. William M. Stone of Flushing. Twelve years before occurred a slight attack of left hemiplegia, from which she gradually recovered, although even yet there is a slight weakness in the left leg. For several years, she had suffered much of the time from quite distressing pains in the arms, legs, and neck. The legs especially troubled her, as she found it impossible to keep them long in one position; and as this symptom was accentuated at night, it greatly interfered with her normal rest. She flushed easily, and her pulse was somewhat rapid. Careful interrogation failed to find any adequate cause for these symptoms. This case responded immediately to treatment as did the other, and in three months she was quite free from every trace of her difficulty. Nearly a year has now passed and she has had no relapse.

Still another case where the causative factor was almost, although not quite, as obscure as these two, is the following:

Case III.—An old lady aged seventy had suffered for more than a year from severe and quite constant pain in the head. Nothing had been found to give her more than temporary relief. Her general health was fair, with no apparent kidney complication, but with a blood pressure of one hundred seventy-five. The treatment resulted in immediate improvement and ultimate recovery. The blood pressure fell to one hundred fifty-five.

Whatever the primary cause all these cases were undoubtedly associated with, or caused by, abnormal

circulatory conditions or blood stasis possibly, for the correction of which no remedy seems quite so prompt and efficient as this. I would not be understood as implying that this treatment demands no care or judgment in its application. When dealing with the combined high pressure and great quantity necessary for these diathermic effects, one cannot assume a too respectful and cautious attitude toward them. The operator must understand what he is doing and never for one moment forget what he is dealing with.

It is far from my wish to magnify unduly this or any other method of physical treatment, but the value of the diathermic method ought to be better understood, and more universally taken for what it is worth.

In emphasizing the exceeding simplicity and value of this treatment, I must point out the fact that not a few physicians are under the impression that they are using an efficient high-frequency current, when all the time they are getting it from a cheap arrangement entirely deficient in amperage or quantity effect. The first cost of an efficient high-frequency outfit is considerable, but after its installation it requires but little care or expense.

HERPES BUCCALIS RECIDIVUS OF THE FOURNIER-EMERY TYPE.

By DOUGLASS W. MONTGOMERY, M.D.,

San Francisco, Cal.

Herpes is a vesicular disease of the skin and of the mucous membranes, and the vesicles may occur either singly or in groups. When the vesicles first appear they have clear sterile contents that afterward become turbid through staphylococcic infection. Subsequently they dry down into scabs that in the course of time are thrown off, leaving a slightly reddened spot that finally disappears without a trace. It is very rare indeed for ulceration with subsequent scarring to occur. On the skin it is the rule for well-formed vesicles to appear, but on the mucous membranes, where the horny layer is very delicate, vesicles as such are rarely seen. The herpes manifests itself either as a single little cup-shaped cavity with a yellow floor, such as is often noticed in "cold sores," or as a little patch with festooned borders and a yellow or grayish surface. This last represents a group where the individual lesions have become confluent. Each curve of the festooned border is a segment of the edge of one of the outer vesicles of the group. As Fournier long ago pointed out, the border of such a patch is microcyclic and polycyclic, and when such a border can be made out the patch is undoubtedly herpes. This arrangement it seems to me is more often seen on the glans and prepuce than in the mouth or on the lips. A short time ago, however, I saw a microcyclic polycyclic patch on the vermilion border of the upper lip that caused the patient a great deal of uneasiness, as she thought it might be a manifestation of syphilis. From these characteristics alone positive assurance was given that it was not luetic. These characteristics, however, of micro- and polycyclicism are infrequently present in any event.

Herpes is usually an insignificant trouble, the lesions being scarcely regarded by the patient excepting as inconvenient, as in "cold sores" for instance. It may, however, be most pertinaceous and exasperating, even leading to suicide, and the main cause for writing the present paper was the occurrence in my practice of three of these distressful cases of herpes of the mouth, that have been designated the Fournier-Emery type.

The immediate causes for an outbreak of herpes are multitudinous, varying in the individual and with the location of the patch. This has forced clinicians into the acceptance of a constitutional disposition, and a sensitiveness of the tissues either to traumatism or infection resulting in herpes. One of the most common causes of herpes is a "cold," and there are people who with every "cold" have a fine blooming out of "cold sores" either in the mouth or on the lips. Herpes in or about the mouth is also a frequent accompaniment of pneumonia. While writing this, Dr. J. Wilson Shiels reminded me that the older British physicians used to consider an abundant herpetic eruption as portending a favorable resolution of the pneumonia. Nowadays we would regard such an outbreak as indicating either a strong resistance to bacterial attack, or a particularly strong infection, or a marked disposition to the formation of herpes. Other disturbances may cause herpes, as some women have an outbreak either on the vulva, vagina, or neck of the uterus, or on some situation of the skin at each menstrual period. Still others get herpes, and this applies especially to young people, when they overeat of candy. In such a case the eruption is most apt to appear in the mouth.

An outbreak of herpes of the mouth may be occasioned by dental work, or herpes of the genitalia may result from coitus, in both instances evidently a sequence of traumatism. It is important to know this as in rape the grayish or yellowish patches may be mistaken for venereal infection. Herpes progenitalis in some men so frequently follows coitus that they learn to associate the act with the eruption as cause and effect. Climate undoubtedly has an influence in some cases. I one time knew a patient who was plagued with an outbreak of herpes of the glans penis, and prepuce every few weeks, and thinking it a venereal disease he was reduced to despair by his malady. During the gold rush he went to Alaska and was gone for over a year, and from the time he left Portland, his shipping port, till the time of his return to Portland he had not a single eruption. On returning to San Francisco he settled down to having his eruption at as frequent intervals as before he left. No other cause of his freedom in the North could be found than change of climate.

But the traumatism of dental work, the traumatism of rape, or the traumatism of coitus would have no effect in producing herpes if the tissues were not in this peculiar manner sensitive or disposed. Neither would the fluxions of blood caused by a common "cold" or by menstruation occasion the eruption if the disposition or sensitiveness was not present. In some this disposition is supposed to be caused by syphilis, in others by rheumatism, in others by malaria, and in still others neither rheumatism, nor syphilis, nor malaria is found to account for the disposition. The following is an instance of a patient in whom rheumatism may have furnished a predisposing cause: This patient used to get a well marked group of herpetic vesicles on the right cheek every four or five years. Her mother had well marked deforming rheumatism of the fingers and of the right knee, and her maternal grandfather for years before he died had to be wheeled in a chair because of rheumatism. The pa-

tient herself had aortic valvular disease because of an attack of acute articular rheumatism and it was after this attack of rheumatism that the herpes of the cheek first broke out. At one time this patient got herpes zoster of the right intercostal nerves, a wholly different disease from herpes, that ran the usual course except that it left the skin of this region sensitive to light pressure for years afterwards. In this case there was neither syphilis, nor tuberculosis, nor malaria, nor any other general disease with the exception of rheumatism to account for the disposition to herpetic attack.

The foregoing is an exposition, as complete as the present state of medical knowledge permits, of the etiology of herpes simplex. A comprehensive statement of this is necessary in order to understand the more complicated etiology of herpes buccalis recidivus, of which the following is an excellent example:

This patient was a salesman for a tobacco firm, and consulted me September 13, 1911, on account of sores on the tongue and lips that he connected with a syphilitic infection acquired three years previously. The patient was a tall large man, not overfat, forty years of age. His chancre had appeared in the usual situation, and was followed by an eruption on the palms and soles. The realization of his predicament, for he was married, caused a profound psychic disturbance, as he was fundamentally a good fellow. After making what reparation he could he separated from his wife. This nervous shock likely contributed to his nervous irritability, of which we shall speak later. Although the patient himself did not have rheumatism his father had suffered severely from it. When the patient first consulted me he had a number of nervous troubles referrable for the most part to his digestive system. He had violent frontal and occipital headaches; he grew nervous and was drowsy and listless through the day and sleepless at night; he would get attacks of headaches, thirst, diuresis and malaise, during which the herpetic patches in the mouth would grow worse; and he had a deep red tongue that at first sight seemed "cobblestone," but was not so. He had the habit of taking protoiodide of mercury pills with a view to curing his malady, and from them would get pain in the left side over the cardiac end of the stomach. His skin was full of blood, as if from intestinal intoxication, and occasionally he would get an eczema, which in one instance at least began as a seborrheic folliculitis on the back of the wrists. The lesion I first saw was a minute affair; a little raw area on the edge of the tongue surrounded by an opalescent border, which indicated more a mucous patch than a true herpes, but it was not pronounced enough either way to be determinative. Although he consulted me to obtain antisyphilitic treatment, and particularly an injection of salvarsan, I dissuaded him from it as being certain that the herpes was due to gastrointestinal intoxication and not to syphilis. He nevertheless went on having attack after attack of herpes, some of which attacks were so severe and involved the lips to such an extent that he could not attend to his work. Finally on October 16, 1911, during a particularly violent outbreak he received an intravenous injection of 0.60 of salvarsan followed by twenty-six rubs of 33 per cent. mercury ointment of five grams each. In one week after receiving the salvarsan the herpes had practically cleared up. For a few weeks he had an occasional solitary vesicle but so slight as in no way to disturb him. Finally even the vesicles ceased to appear.

This is not, however, all of this man's history in which we are at present interested. On April 1, 1912, four and a half months after receiving the salvarsan injection above referred to, he called, complaining of nausea, vomiting, nervousness, a circumscribed distressed area in the median line of the abdomen just above the navel, a seborrheic folliculitis of the thighs, and a seborrheic eczema of the forearms. There was neither sugar nor albumin in the urine, but there was much indican blue, and a green tinge with nitric acid as if from bile. He had had a steady pain over the liver for the past two months. His Wassermann was slightly positive. He was not at this time in a position to take another injection of salvarsan. He called again January 7, 1914, complaining of gastrointestinal disturbance, and the following day he was given an intravenous injection of neosalvarsan (0.90 grams), and ten days thereafter an herpetic patch, about one inch in diameter, broke out on the left buttock. The patch was red with a purplish tint, and round about was a rather broad light red erythematous halo. The eruption was accompanied by a slight burning sensation, and so attracted his attention, otherwise he would not have been aware of its existence. He had never had herpes of the free surface before and had had no herpes of the mouth since shortly after receiving the salvarsan-mercury treatment in 1911. It may here be remarked that he had not taken mercury by the mouth since some time previous to his first salvarsan injection, but he had never given up the use of tobacco; the relevancy of this observation will be taken up later. This attack of herpes of the buttock cleared up without incident, and I went on giving the patient a course of injections of grey oil according to my usual custom. It is to cases such as these that the term herpes recidivus buccalis is applied.

In the above instance we have a most complicated etiology. Although the patient was not rheumatic himself, one of his immediate ancestors was markedly so, and he was subject to gastrointestinal disturbances that are frequently associated with rheumatism, and the gastrointestinal irritation and intoxication would of themselves render the mucous membrane of the mouth sensitive. Besides this his nervous system was in a highly irritable condition, and there is always a feeling that herpes and irritability of the nerves are linked together etiologically. Besides this the patient used mercury and tobacco, both of which are irritants for the buccal mucous membrane and are regarded as incitors to herpetic attack. In these cases of herpes recidivus buccalis, syphilis occupies a peculiar position etiologically. Fournier and Emery found lues present in nineteen out of twenty cases. The attacks usually begin in the early stages of the disease between the first and fourth years, to last indefinitely, and before the introduction of salvarsan they were most refractory to treatment. Fournier considered that the recurrence of syphilitic lesions in the mouth, together with the use of mercury and tobacco, furnished the local irritation necessary to bring on the attacks of herpes. Trautmann* considers that syphilis may contribute in two ways to the occurrence of these distressful cases. Like Fournier, he thinks that it may act as a local irritant through the local recurrence of true syphilitic lesions in the mouth, and besides this, by the development of a constitutional change or disposition, it may render the tissues so sensitive that a trivial local irritant may bring on an attack. However this may be, there is no doubt of the importance of syphilis as an etiological factor in the present case, as he was cured of his buccal attacks by salvarsan, an eminently good antisyphilitic remedy. The effect of arsenic as an epithelializer may have contributed somewhat to this result, as I never saw a mouth clear up so rapidly under any remedy as occurred here. This epithelializing effect would, however, be only temporary, whereas the cure has for over two years been permanent. The patient, however, still maintains his herpetic disposition or diathesis, as shown by the patch breaking out on his buttock after the second dose of salvarsan, and salvarsan may have been the immediate cause of this, as herpetic outbreaks both of herpes and of herpes zoster are well known to occur on giving arsenic.

*Trautmann, Gottfried: "Die Krankheiten der Munhöhle und der oberen Luftwege."

Disturbances of the digestive tract have been mentioned as being capable of giving rise to herpes, and I have seen two instances resembling absolutely the Fournier-Emery type of herpes recidivus buccalis that seemed to rest on this basis alone. At least the digestive disturbances were present and their management brought about a decided amelioration of the conditions in the mouth and also of an eczema ani, which was present in each case. In neither of these was there any history of syphilis and repeated Wassermanns were negative. Nor was there any history of rheumatism or malaria.

323 Geary Street.

RETROPHARYNGEAL ABSCESS.

By B. A. FEDDE, M.D.,
Brooklyn, N. Y.

The following cases, comprising my experience in private practice, are cited to show the unsatisfactory clinical course of this condition, even when it is recognized quite early:

Case I.—C. A., male, 13 months old, was seen Feb. 6, 1909. He had been languid and feverish for three days. Refused breast. Seems to have some difficulty in swallowing. There is an occasional snoring respiration. Right sub-axillary region is swollen. No cough. T., 105.4°. P., 180. R., 34, occasionally snoring. Throat: tonsils much enlarged, no membranes visible. Field obscured by mucus and milk. Heart and lungs normal. Abdomen moderately distended, tympanitic.

Diagnosis.—Tonsillitis.

Calomel and castor oil and mixture containing potassium chlorate and tincture of iron chloride in glycerin were prescribed.

Feb. 7.—Bowels have moved freely. Some stiffness of neck. Coughs. Slept poorly. Dysphagia continues. T., 105°. P., 210. R., 40, noisy, snoring. Throat shows swollen uvula and tonsils. No membrane. Palpation discloses the same. Gave antitoxin, 5,000 units.

Feb. 8.—Patient looks better. Slightly more interested in surroundings. T., 104.4°. P., 162, strong. R., 50, less noisy. Rigidity of neck persists, apparently painful. Winter's and Kernig's signs both negative. Throat somewhat less swollen. Much mucus. Heart normal. Lungs, a few fine moist râles in right lower lobe.

Diagnosis.—Retropharyngeal abscess (?). Continued treatment.

Feb. 9.—T., 100.6°. P., 150. R., 50. Soft swelling in posterior pharyngeal wall. Lungs show numerous fine moist râles generally distributed. Ordered creosotal ♏ v every four hours. Incised pharyngeal swelling. No pus found.

Feb. 10.—Both ears discharging. T., 100.6°. P., 135. Ordered warm boric acid irrigations.

Feb. 12.—Condition unchanged. T., 99°. P., 132. R., 30. Both ears discharging freely. Respiration snoring. Lungs contain creaks and sibilant and sonorous râles. Very few moist râles. Throat looks clearer. Posterior pharyngeal wall exhibits a soft swelling. Mother refused another incision and the case was discharged. Subsequently a throat specialist was consulted. He evacuated the abscess and the patient recovered.

Case II.—E. F., female, 3 years old, was seen April 26, 1911. The following history was recorded: Patient had always been puny with a capricious appetite. Has had varicella since April 18. For three days has been feverish. Anoxexia. Vomiting. Bowels constipated. Complains of stiff neck. T., 101.2°. P., 120. R., 30, quiet. Color and nutrition poor. Mouth breather. Tongue heavily coated. Breath foul. Throat negative to inspection. Heart, lungs, and abdomen normal. Enlarged cervical gland on right side.

Diagnosis.—Rheumatic fever. Salicylate of soda was prescribed.

April 28.—Patient is no better. T., 102°. P., 130. R., 30. Retropharyngeal bulging. Much salivation. Stiffness of neck. Easily bent forward; cannot bend backward.

Diagnosis. — Retropharyngeal abscess. Incised. Considerable pus evacuated. Recovery was rapid and uneventful.

Case III.—I. P., male, 7 months old, was seen March 16, 1914. Was a bottle-fed baby, one of twins, with vomiting habit and consequent malnutrition and constipation. The following history was recorded: Child has been ill two days. Feverish. Left ear discharging. Coughs. Stiffness of neck. Slight swelling of left side of neck. T., 100°. P., 160. R., 50, noisy, oral. Heart and lungs normal. Abdomen normal. Left ear shows perforation in drum membrane. Throat negative to inspection. Palpation shows swelling in posterior pharyngeal wall on the left side.

Diagnosis.—Retropharyngeal abscess (Otitis media). Boric acid irrigations were ordered for the ear and next day the pharyngeal swelling was incised. No pus evacuated, but there was immediate though partial improvement in breathing.

March 19.—T., 103.2°. P., 180. R., 40, oral, less noisy. Left ear drum is again bulging; there has been no discharge for one day. Incised drum membrane. Continue boric irrigations.

March 21.—T., 102°. P., 150. R., 40. Child coughs. Lungs have a few scattered, moist râles in both sides. Ammonium chloride and ipecac were prescribed.

March 24.—T., 101°. P., 160. R., 40, noisier than on last visit. Vomits all medicine, even including milk of magnesia. Abscess has reformed. Incised, evacuating large amount of foul pus. Ordered sweet oil enemas daily. Sinapisms to chest. Stop all medication.

March 27.—T., 98.6°. P., 120. Small swelling in left side of posterior pharyngeal wall. No fluctuation. Ear dry. Case discharged.

Anatomy.—"The posterior pharyngeal wall is inclined upward and forward, and forms the vault of the pharynx above by meeting the anterior wall at a rounded angle. On the upper part of the posterior wall, at and above the level of the Eustachian orifices, there is seen, particularly in early life, a considerable collection of lymphoid tissue, associated with a thickened and folded condition of the mucous membrane in the child. This is the pharyngeal tonsil; upon the center of the pharyngal tonsil is an orifice leading into a small recess into which numerous mucous glands open.

"The lymphatics of the pharynx pass chiefly to the upper set of deep cervical glands. Those from the upper part of the posterior wall join a few post-pharyngeal glands which are found on each side between the pharynx and the rectus anticus major muscle, in front of the upper two vertebræ. These latter glands, which are large in the child, small in the adult, but apparently always present, are of considerable clinical interest, as they often form the starting point of post-pharyngeal abscess. They receive affluents from the prevertebral muscles and fascia, and the posterior part of the nose" (Cunningham).

From this it is seen that infections entering the mucous membrane of the posterior part of the nose or the nasopharynx, whether lesions are produced at the port of entry or not, may cause retropharyngeal lymphadenitis, which may go on to abscess. The swelling may be quite large before abscess forms, according to Holt. In two of my cases cited above, early incision evacuated no pus, while a later one succeeded.

Symptoms and Diagnosis.—When fully developed the cases are said to present these characters: Fever and prostration, changed cry resembling a quack, dysphagia, obstructed breathing, noisy mouth breathing, a fixed position of the head backward and toward the affected side, swollen glands at the angle of the jaw, and visible pharyngeal bulging. If the physician is called early in the disease there is frequently nothing evident but a sick baby with fever, and, at most, rhinitis to account for it. Later it may bear a superficial resemblance to adenoids, croup, or laryngeal diph-

theria. Indeed, Kerley has seen a case complicating laryngeal diphtheria.

The condition is frequently overlooked, simply because the attendant omits palpation of the pharyngeal wall. Inspection under the usual conditions of a squirming, gagging infant giving but momentary glimpses of the throat seldom reveals it.

To palpate properly, have the child seated in the mother's lap, its right side toward you. Stand beside it, your left hand flat on its left cheek, pressing the head against your side. Get the mouth open, then gently push the cheek between the jaws with your middle finger, and introduce the palpating index finger of the right hand rapidly back, exploring nasopharynx and oropharynx as far down as possible. This measure should be employed in every case of obstructed breathing, no matter how clear the diagnosis may seem.

Treatment.—Some neglected cases, and those arising from vertebral caries point in front or behind the sternomastoid, and are best incised externally under antiseptic precautions, and drainage inserted. More frequently the abscess is found pointing into the pharynx, and may rupture spontaneously. It requires some judgment to decide when the swelling should be incised. I believe now that in Case III, and possibly Case I, cited above, suppuration had not taken place when incision was first made, though the mass was soft and large. Yet early incision in Case III gave partial relief to breathing, and was, therefore, justified. Furthermore, it may be noted that these two cases were complicated, it may be noted that otitis media, the latter probably caused by extension of the infection and by interference with drainage.

Anesthesia is dangerous. Many authors say the mouth-gag is also extremely dangerous, and should not be used. Most pediatric surgeons operate with patient in upright position; but Coakley advises that the head be held lower than the body. Many descriptions of the operation presuppose a trained assistant and nurse, which are not always available.

I have learned that with inefficient assistance the upright position means too small an incision, perhaps even insufficient penetration, and that the head-mirror is worse than useless. I tried both in my first case, and it was torture for patient and mother. The following procedure is rapid but deliberate, simple, and thorough.

The attendant sits facing me and lays the child's head in my lap, which has been protected with towels. At my right is a good light. The Denhard mouth-gag is introduced on the left side and opened, while the little finger hooked under the chin keeps the jaw, and with it the hyoid bone and the tongue, well forward, thus avoiding the sudden asphyxia which authorities speak of, and which undoubtedly is caused by the crowding of the hyoid structures upon the swollen pharyngeal wall. The same hand may manage a bent spoon acting as a tongue depressor, while the right introduces the bistoury, guarded to within one-half inch of the point, perforating the most prominent part of the abscess, then enlarging the incision downward.

The head has up to this time been turned partly to the side. As soon as pus wells up the child is turned over completely on its face, that the pus may be freely spit out. Later the finger is introduced and any septa present are broken up.

The after-care is simple: Food, tonics, cod-liver oil; but the child should be watched for several days, as the cavity occasionally refills.

In case external incision is decided upon, Hilton's method of operating has been recommended. A one-inch incision is made behind the sternomastoid, starting one inch below the mastoid tip, and deepened to expose the muscles of the floor of the posterior triangle. Then with blunt dissection the wound is deepened, passing behind the vessels and nerves of the neck, using a grooved director under the guidance of one finger in the pharynx. When the abscess cavity is entered a closed forceps is inserted, opened and withdrawn, and a drainage tube inserted, properly guarded against disappearing into the wound.

378 Ninth Street.

Medicolegal Notes.

Disqualification of Physicians as Witnesses.—The Arkansas statute, Kirby's Dig. §3098, provides that no person authorized to practice physic or surgery shall be compelled to disclose any information which he may have acquired from his patient while attending him in a professional capacity, and which was necessary to enable him to prescribe as a physician, or to act for him as a surgeon or trained nurse. In an action upon a life insurance policy it was held that where the insured's attending physician requested another physician to accompany him on a visit to the insured in order that the attending physician might have the benefit of the other's opinion with reference to the insured's condition, and both examined the insured and consulted concerning his ailment, both were disqualified to testify in the case.—Mutual Life Ins. Co. v. Owen, Arkansas Supreme Court, 164 S. W. 720.

Malpractice—Insufficient Evidence.—In an action for negligence against a physician for closing a wound without first removing a piece of gauze, the petition charged "the *defendant* negligently and with gross negligence, unskillfully and unprofessionally *closed* the wound made by said operation, without first removing therefrom" a piece of gauze. It was proved by the plaintiff's own testimony that the wound was not closed by the defendant, and was not closed by nature until long after the plaintiff had left the care of the defendant. The expert called by the plaintiff refused to testify that the presence of the sponge was hurtful or leaving it where the defendant did showed negligence. In fact, there was no evidence whatever that the presence of the sponge had been injurious. Judgment for the plaintiff was therefore reversed, it being held that the evidence was insufficient to go to the jury.—Boner v. Nicholson (Mo.), 161 S. W. 309.

Liability for Medical Services to Another. — In an action for medical services, the controlling issue in the case was whether the defendant contracted, as an original undertaking, to assume liability for medical services to be rendered in behalf of another by the plaintiff, who was a physician. The evidence authorized a finding that, even if the defendant did not expressly contract to pay the plaintiff for medical services rendered the defendant's son (who was *sui juris*), it was at least understood by both the plaintiff and the defendant that the plaintiff would not perform further services unless he was employed by the defendant; and the defendant, by accepting the contract, upon the condition and in the sense in which he knew it was understood by the plaintiff, must be held to have assented to it in that sense.—Reinschmidt v. Dorough, Georgia Court of Appeals, 81 S. E. 252.

Action for Services—Implied Contract.—In an action for professional services it appeared that the plaintiff, a physician and surgeon, was called to a hospital late one night by some person unknown to attend the minor son of the defendants. The son had received an injury, and an immediate operation was necessary. The plaintiff performed the operation with the acquiescence of the defendants and continued to treat the patient with their knowledge and assent. The defendants were liable upon implied contract, but the plaintiff's complaint alleged that the services were rendered at the special instance and request of the defendants. It was held that the addition of this allegation made the pleading one upon both express and implied contract, and did not defeat recovery upon the implied contract.—Lufkin vs. Harvey, Minnesota Supreme Court, 147 N. W. 444.

TRAUMATIC SPONDYLITIS.

IN 1891 Kümmel applied this name to what he regarded as a definite clinical entity. The rôle of traumatism was apparently clearly established in the five cases that he reported. Three distinct stages of the disease were delineated: the first corresponding to the few days following the traumatism and characterized by the presence of pain in the region of the original injury; the second marked by apparent well-being; and the third distinguished by the development of a kyphosis and the onset of radiating pains. This condition was attributed to a rarefying osteitis involving the bodies of one or more vertebræ and resulting in a deformity.

Nicola Caprioli (*Giornale Internazionale delle Scienze Mediche*, September 15, 1914) reviews a series of fifty-four cases of this condition which have been reported in the literature, including two of his own, and comes to the conclusion that there is sufficient evidence to substantiate the original claims of Kümmel about which considerable controversy has arisen. Many have been the theories advanced to explain the clinical and pathological phenomena in so-called Kümmel's disease: Helle suggesting vasometer disturbances; Goltz and Kroening citing an experimental osteoporosis of the vertebral bodies secondary to trophoneuratic changes in the adjacent spinal cord; Virchow and Recklinghausen advancing the hypothesis of an osteomalacia or rarefying osteitis of the spine; Mikulicz pointing out the possible rôle of an intra- or extradural hematoma; Schede, Kirmisson, and others believing in the existence of an actual fracture of the vertebral column without mobility of the fragments but with a slow attrition of the latter; and finally Oberst including all cases of traumatic spondylitis within the broad classification of tuberculosis of the spinal column.

Comparatively few cases of this condition have come to autopsy. Examination of all the clinical histories reported indicates that little has been added to the original picture portrayed by Kümmel, the chief features of which are as follows: Sequent to a direct or an indirect injury to the spinal column, the patient complains of pains which may last from a week to several months and which may or may not be accompanied by symptoms of spinal commotion, such as motor or sensory disturbances in the legs, sphincteric impairment, etc. Little by little all symptoms disappear and the patient feels perfectly well. This stage of apparent health lasts for a period varying from several months to several years, after which the patient again begins to experience pains radiating from the site of the original injury into the hips and legs. At the same time there appears the vertebral deformity which is usually a kyphosis, though sometimes a scoliosis or kyphoscoliosis, slowly and progressively increasing unless arrested by suitable orthopedic treatment. In making a diagnosis of Kümmel's disease there must be excluded Pott's disease, acute osteomyelitis of the spine, syphilitic spondylitis, and traumatic syringomyelia. The possible aid of the *x*-rays should not be overlooked.

The conclusion is reached that traumatic spondylitis is the result of a direct or indirect injury of the spine followed by a rarefying osteitis of the spongy tissue of the vertebral bodies. The original traumatism may be a contusion of the bone or an actual though latent fracture.

ARSENIC EATERS.

FOR about a generation we have ceased to hear accounts of the Alpine toxiphagists who fairly consume arsenic and are the better mountain climbers therefor. No doubt a feeling of scepticism has been engendered as a result of this silence, which also extends to the society women who are reputed to secure for themselves an aristocratic pallor and transparency of skin by a similar consumption of this mineral. So, too, the stories of wall paper poisoning are no longer heard, although it is probable that arsenical paper is used as much as ever, despite all protective enactments. No well-informed person doubts for a moment that all these beliefs have a solid foundation in fact: but there should be some word of explanation as to the continued silence of the medical and lay press on such subjects. In cases of alleged homicidal poisoning with arsenic, it is the policy of the defence to claim that the victim was an arsenic addict. In this way the question of arsenicism is kept alive, but these forensic cases make no lasting impression on the public mind.

At a session last summer of the Berlin Society for Medical Jurisprudence (*Berliner klinische Wochenschrift*, October 26), Fraenckel discussed the subjects of arsenic eating and arsenical poisoning. He claims that the former is a widely spread custom or vice, but that little is known of its consequences. The supposed beneficent results are increased sexual potency, a subjective feeling of increased muscular power, and a relative immunity towards infectious diseases. The maximum tolerated daily dose may reach twenty grains of arsenous acid! If the drug ingestion is suddenly suppressed, very severe deficiency symptoms may result, even death itself. In alleged deliberate slow poisoning from arsenic, it might become necessary to discriminate between excess and defect symptoms. In prolonged ingestion of large doses for whatever motive, the drug should be found stored in the spongy tissue of the small flat bones. Hence autopsy finds

cannot distinguish between addiction and homicidal feeding.

The course of the symptoms might serve to distinguish between the two types of cases, but here again the parallelism does not fail; for the addict when he begins the use of the drug may show toxic or intolerance symptoms, just as may the victim of a poison plot. Animal experiment throws no light on the situation, for progressive immunity cannot be developed in animals. There is upon record the case of an addict who ingested arsenic freely per os (his stools containing large quantities of the drug), but who was killed by a relatively small subcutaneous injection. All of which goes to show that the silence on arsenicism may be a natural result of the extreme difficulties associated with the subject of addiction to a drug which does not influence the behavior and which causes no specific phenomena.

SURGERY IN MODERN WARFARE.

No one who heard the presidential address of Dr. Antoine Depage of Brussels before the fourth Congress of the International Saciety of Surgery held in New York in the spring could fail to be impressed with its eloquence. The speaker when he delivered it little knew its timeliness, and moreover in the face of recent occurrences his proud boast that "it was the privilege of little Belgium to offer a meeting place for the learned of all countries, as she was covered by Europe herself with the shield of peace and liberty" has been disproved in the most terrible manner. However, Dr. Depage's address on the surgery of war was most valuable and practical, seeing that he had gone through the Balkan wars in the capacity of a surgeon.

Among other apt phrases used by the speaker was that the fate of the wounded depended above all on the aid given on the line of battle, for as long as the engagement lasted the ground was inaccessible to the ambulance men; hours passed during which the wounded were helpless. It was therefore necessary to instruct every soldier in the principles of first aid to furnish him with a properly fitted surgical packet. He must realize fully the danger of infection from earth, dust, and water. Of what use was a sterilized compress if it became soaked in polluted water? No operating should be done in the temporary hospital stations at the front; they should simply serve as places where the sick and wounded were sorted out. Violation of this rule in the Balkan wars produced deep suppuration in wounds. Operations must be reserved for the hospitals of the second line, which remained fixed and unchanged and should be manned by experienced surgeons.

Little has become known as yet with regard to the treatment of the wounded on the battlefield during the present war, and although the Balkan wars were noted for their ferocity, it is probable that the fighting now going has never been surpassed in fierceness and in disregard for human life. Undoubtedly, so far as is possible, the wounded have been well cared for surgically, but the numbers injured have been so enormous that it is unreasonable to imagine that a considerable proportion of those struck by shell, bullet, or steel have been efficiently treated. There is a limit to human powers, and the powers of the surgeons in this war have been taxed in many cases beyond this limit.

FIRST AID DENTISTRY IN THE GERMAN ARMY.

In the present war dentistry will very likely be raised to the dignity of a surgical specialty in the dressing stations and field hospitals, and the work there initiated will be continued in the relay and reserve hospitals. Of even greater significance for the common welfare, however, is dental prophylaxis before hostilities begin. While teeth with diseased pulp should not be sacrificed, all dead roots had best be extracted, lest they give rise to abscesses and fistulæ.

First aid dentistry is considered by Dieck in an article in the *Deutsche medizinische Wochenschrift* for October 8. Hitherto the dentist was instructed to assume activity only in connection with the relay hospital, save in case of emergencies, when his presence might be desired at the field hospital. He was not supposed to visit the dressing stations either in time of battle or otherwise. Nevertheless, there is a class of cases in which first aid by dental surgeons should be indispensable. These comprise injuries to the jaws, from any cause whatever—falls, blows, projectiles, horse-kicks. Expert technical skill at such junctures may prevent necrosis of the bones. For example, let us suppose that a piece is carried away from the superior maxilla and lies free in the buccal cavity save for soft part attachments. Only immediate reposition and fastening can save this fragment. As a rule the jaw cases may be properly cared for at the field hospital and sent directly home, as a first duty here is to render cases transportable, while first aid in the field is to meet the severest emergencies. Rapid direct transportation to a reserve hospital will give these wounded the benefit of the best dental talent. The Army Sanitary Order of 1907 provided only two dental surgeons and one technician for an entire army corps, who were to be in attendance at the regular military hospital. It is very probable that this limited service will be greatly augmented during the course of the war.

Pulmonary Wounds in the European War.

The enormous casualties in the present war are certain to result in a vast amount of new data for teaching, whether or not such knowledge can be directly applied to the injuries sustained in civic life. Thus von Hösslin (*Berliner klinische Wochenschrift*, October 12) was able to follow up 18 cases of wounds of the lung from the time they were inflicted. All but two of the soldiers, irrespective of their position at the time, fell prostrate and many lost consciousness. Pain was not complained of; instead it was dyspnea or sense of suffocation. In all but two cases blood was expectorated, while many also bled from the wounds. Extravasations were absorbed very slowly. The heart in a number of cases was displaced to the opposite side. Treatment was entirely expectant in character. As a rule pneumothorax was promptly absorbed. There were

but three complicated cases, two by empyema, while the third was due to a separate wound of the trunk. The other patients were already convalescing.

Cheap Remedies for First Aid in War.

According to the Military Supplement of the *Münchener medizinische Wochenschrift*, September 29, the following remedies have been recommended as adapted to general use on the battlefield: Crude turpentine as a wound dressing (it is painless and does not irritate the kidneys); pure liquid paraffin as a dressing for severe wounds (iodoform may be added up to 2 or 2.5 per cent.); sublimate solutions, 1:3000 or 1:5000 being sufficiently strong, for antiseptic wound dressing; tincture of iodine, 5 per cent. instead of 10 per cent. for the same purpose. For diarrhea, cognac with the addition of a few drops of iodine tincture is a practicable resource. Von Hösslin proposes the revival of an old internal remedy in wound infection, the basis of which is bichloride of mercury and potassium iodide (the latter to remove the metallic taste of the mercury). The daily dose of mercury is from 0.015 to 0.02 gm. (about ¼-grain) to be taken for several successive days.

News of the Week.

New York's Death Rate.—For the week ending November 28 there were 1,389 deaths in this city, making a death rate of 12.98 per 1,000 of population. This rate is considerably higher than the rate for the corresponding week of 1913, which was 12.51, the difference being equivalent to 101 deaths. This increase is due to the greater number of deaths from diphtheria, croup, and diseases of the respiratory tract.

Street Accidents.—According to the report of the National Highways Protective Association, recently issued, thirty-eight persons, twenty of them children under 16 years of age, were killed by vehicular traffic in this city during November. Automobiles caused the death of 24, wagons killed 8, and trolleys 6. Of the fourteen children killed by automobiles five were roller skating. The report shows that for the last eleven months 591 persons were killed by automobiles in the State, 152 by trolley cars, and 146 by wagons. Of this total number 247 were children under sixteen years of age. In New Jersey in November 22 persons were killed by automobiles, 3 by trolleys, and 2 by wagons.

Typhoid Fever in Detroit.—In a recent discussion before the Wayne County (Mich.) Medical Society it was stated that Detroit was one of the worst typhoid cities in the United States, the reason being a contaminated water supply. In answer to this Dr. John E. Clark publishes the following record of typhoid cases for the past eleven months—a very low record: January, 6; February, 2; March, 5; April, 1; May, 5; June, 3; July, 11; August, 9; September, 10; October, 4, and November, 4; giving a total of only 60 cases in nearly a year. Of these cases Dr. Clark says a number have been traced to infected milk, but not one directly to the city water supply.

Dr. Carl von Ruck's Experimental Work on Tuberculosis Immunization, described in the Medical Record of August 31, 1912, has recently been confirmed in Sir Almroth E. Wright's laboratory in London.

Banquet of the Philadelphia Neurological Society.—On the evening of November 28 a banquet was given by this Society at the Art Club, the invited guests including Dr. George W. Jacoby, representing the American Neurological Association, Dr. Morton Prince of Boston, Dr. Hugh T. Patrick of Chicago, Dr. Smith Ely Jelliffe of New York, Dr. Edwin N. Brush of Towson, Md., Dr. Henry M. Thomas of Baltimore, and Dr. William L. Rodman, President-Elect of the American Medical Association.

Dr. Malcolm S. Woodbury has been elected superintendent of the Clifton Springs Sanitarium, to succeed the late Dr. Mumford. Dr. Woodbury has long been connected with the institution.

Dr. Albert Calmette, Director of the Pasteur Institute at Lille, who has been acting as one of the chiefs of the medical service of the French army, is a prisoner of war at Münster, Westphalia.

Absorbent Cotton for Russia.—On two steamships that have sailed recently for Vladivostok via the Panama Canal are 1,000,000 pounds of absorbent cotton, and a third will soon take another 500,000 pounds by the same route.

Dr. Duncan's Autotherapy Endorsed.—A committee appointed last February to investigate Dr. Charles H. Duncan's method of autotherapy in the treatment of infectious diseases has recently made a report to the Homeopathic Medical Society of the County of New York commending the procedure as sound in principle and giving good results in practice. The membership of the committee consisted of Drs. Seward, Harrington, Laidlaw, Dieffenbach, Gillingham, and Stearns. The investigations of the committee were carried out in the fields of both human and veterinary therapeutics. In the latter it was found that autotherapy was of especial value in all septic conditions, in ozena, acute infections of the hoof, necrosis of the withers, and lacerated wounds of the legs involving the tendon sheaths in horses, some of which conditions were formerly regarded as incurable. In the field of human therapeutics the committee reviewed articles which had appeared in the Medical Record and elsewhere, examined patients treated by the method, and took the testimony, verbal and written, of physicians who had employed autotherapy. The committee found that the technique of autotherapy required further elaboration and precision in the size of the dose and the interval between doses, but that this did not detract from the soundness of the principle, nor should it take from Dr. Duncan the credit of being the first to see the principle clearly and of having started autotherapy on a sound practical basis. Dr. Duncan was also commended for having made no secret of his method, for having given the work freely to all inquirers, being actuated by a high sense of professional honor and of responsibility to the sick, and for having refrained from exploiting the method among the laity at a time when some of his fellow physicians were hostile and his friends indifferent.

Medical Missionary Conference.—The Sixth Inter-Denominational Medical Missionary Conference was held in Battle Creek, Mich., November 17-20, about 200 workers from home and foreign fields being in attendance. The meeting was presided over by Bishop E. R. Hendrix of Kansas City. The probable effect of the war on mission work was very generally discussed, the consensus of opinion being that a temporary withholding of mission gifts would be experienced, but that the final effect would

be a broader brotherhood and a most salutary condition in mission work in general. Among the most notable addresses delivered were the following: "Medicine in China," Reverend Isaac T. Headland, Pekin, China; "Better Organization for the Medical Work," Reverend Levi B. Salmans, Mexico; "Physiological Therapeutics on the Mission Field," Dr. J. H. Kellogg, Battle Creek Sanitarium; "Forty-five Years in Asiatic Turkey," Reverend George C. Raynolds, M.D., D.D., Van, Turkey; "The Outlook for Missions in View of the War," Bishop Eugene R. Hendrix, D.D. The Conference will meet again in 1915 at Battle Creek.

Medical Society of the County of New York.—The one hundred and ninth annual meeting was held November 23, the entire evening being devoted to the executive session, especially to a consideration of the proposed amendments to the By-Laws, all of which were defeated after a prolonged and animated discussion. The following motion, made by Dr. William S. Gottheil and amended by Dr. Henry S. Stark, was unanimously adopted: "That the schedule of fees for physicians working under the Workman's Compensation Law is insufficient compensation, and is hereby repudiated by the Medical Society of the County of New York; and that its delegates to the State Society are instructed to introduce a resolution to the same effect at the next meeting of the State Society and to support it in every way possible." The announcement of the result of the election of officers and delegates will be made at the meeting on December 28.

Harvey Society Lecture.—The fifth lecture of the series will be given at the New York Academy of Medicine, 17 West Forty-third Street, on Saturday evening, December 12, at 8.30 P. M., by Prof. L. J. Henderson, of Harvard University. Subject: "The Excretion of Acid in Health and Disease."

Medical Society Elections.—At the annual meeting of the New York Academy of Medicine, held December 3, 1914, the following officers were elected: *President*, Dr. Walter B. James; *Vice-President*, Dr. Edward D. Fisher; *Corresponding Secretary*, Dr. D. Bryson Delavan; *Treasurer*, Dr. Reginald H. Sayre; *Trustee*, Dr. Wisner R. Townsend; *Member of Committee on Library*, Dr. Lewis F. Frissell; *Members of Committee on Admission*, Dr. N. R. Norton (5 years); Dr. W. L. Stowell (3 years); Dr. W. L. Niles (1 year).

The St. Louis Medical Society elected the following officers at its annual meeting on November 25: *President*, Dr. R. Emmett Kane; *First Vice-President*, Dr. Emmett North; *Second Vice-President*, Dr. William H. Luedde; *Secretary*, Dr. F. C. Kuhlmann; *Members of the Council*, Drs. A. M. Koetter, Joseph Grindon, G. Richter, and Ralph Thompson. The council will meet next month and elect the treasurer.

The Southeastern Iowa Medical Association, at its thirty-ninth annual meeting, held in Mt. Pleasant, November 19, elected for the coming year the following officers: *President*, Dr. A. O. Williams, Ottumwa; *Vice-President*, Dr. C. A. Boyce, Washington; *Secretary and Treasurer*, Dr. E. F. LaForce, Burlington. Washington was chosen as the next place of meeting.

The Wabash County (Ill.) Medical Association elected the following officers at its annual meeting held at Mt. Carmel, November 24: *President*, Dr. P. G. Manley; *Vice-President*, Dr. W. H. Roberson; *Secretary*, Dr. J. B. Maxwell; *Treasurer*, Dr. W. B. Baird; *Censor*, Dr. E. A. Buchholz; *Delegate to the State Society*, Dr. J. J. McIntosh; *Alternate*, Dr. C. E. Gilliatt.

The Middle Tennessee Medical Association, at its annual meeting held in Murfreesboro, November 19 and 20, selected Lebanon for its next place of meeting in May, 1915, and elected the following officers: *President*, Dr. O. N. Bryan, Nashville; *Vice-President*, Dr. B. F. Reagor, Shelbyville; *Secretary and Treasurer*, Dr. R. W. Billington.

Obituary Notes.—Dr. STEPHEN C. PETTIT of Brooklyn, N. Y., a graduate of the Long Island College Hospital in 1895, a member of the Brooklyn Pathological and the Brooklyn Medical Societies, died at his home on December 3, from blood poisoning contracted during the course of an operation, in his forty-third year.

Dr. CHARLES HENRY REED of Philadelphia, a graduate of the University of Pennsylvania, Department of Medicine, in 1878, died recently at his home.

Dr. CHARLES H. MORDOFF of Genoa, Ill., a graduate of the Chicago Homeopathic Medical College in 1881 and of the Hahnemann Medical College and Hospital, Chicago, in 1903, and a member of the Illinois State and the Vermilion County Medical Societies, died at his home after a short illness on November 16, aged 58 years.

Dr. ROBERT M. SADLER of Okolona, Miss., a graduate of the Louisville Medical College, Louisville, Ky., in 1877, died suddenly at his home on November 10, aged 65 years.

Dr. GEORGE WASHINGTON BOYD of Washington, D. C., a graduate of the College of Physicians and Surgeons, Baltimore, in 1895, and a member of the American Medical Association and the Medical Society of the District of Columbia, died at his home from Bright's disease, after a long illness, on November 22, aged 55 years.

Dr. MARSHALL T. SHIVELY of Marion, Ind., a graduate of the Medical College of Ohio, Cincinnati, in 1874, and a member of the Indiana State Medical Association and the Grant County Medical Society, died at his home from cerebral hemorrhage on November 23, aged 65 years.

Dr. SAMUEL W. COOMBS of Bowling Green, Ky., a graduate of Vanderbilt University, Medical Department, Nashville, Tenn., in 1885, and a member of the Kentucky State Medical Association and the Warren County Medical Society, died at his home suddenly, on November 20, aged 52 years.

Dr. CHARLES BAILEY SIMCOE, first assistant physician at the State Hospital for the Insane, Nevada, Mo., a graduate of the Missouri Medical College, St. Louis, Mo., in 1884, died on November 21, aged 54 years.

Dr. SARAH C. MILLEN of Omaha, Neb., a graduate of the College of Physicians and Surgeons of Keokuk, Ia., in 1882, died at her home from paralysis, on November 22.

Dr. CLARK M. GALLOWAY of Xenia, O., a graduate of the Medical College of Ohio, Cincinnati, in 1877, and a member of the Ohio State Medical Association and the Greene County Medical Society, died on November 20, after a short illness, aged 70 years.

Dr. FREDERICK SEITZ died of apoplexy at Philadelphia on November 23 at the age of 63 years. He was graduated from Jefferson Medical College in the class of 1886.

Dr. GEORGE S. CRAMPTON has been elected attending surgeon to the eye department of the Pennsylvania Hospital in succession to Dr. Peter N. K. Schwenk resigned.

Correspondence.

CHOLERA IN AUSTRIA.

To the Editor of the Medical Record:

Sir:—In the issue of the Medical Record of October 24 I find among the news of the week under the heading "Cholera in Austria," a report from Rome saying that there are several thousand cases of cholera in Galicia and Hungary, and that the Russian army has withdrawn from Hungary, repelled by the comma bacillus rather than the Austrian bullets.

I wish to state that the cholera appeared in Galicia only after the first weeks of the war, when the Austrian army came in contact with the Russians and made the first prisoners (from Padolia) who brought with them the Asiatic sickness. Before the war there were no cases of cholera in Austria-Hungary, and it will be easily believed that sanitary conditions in Austria are in a little better state than in Russia.

The Austrian State Department of Health is publishing daily and weekly, as is done in the United States, every case of infectious disease, and up to the present there have been only a few hundred cases, all among soldiers and privates returned from the northern theatre of war.

Dr. Alfred Brunner.

OUR LONDON LETTER.

(From Our Regular Correspondent.)

BRADSHAW LECTURE AT ROYAL COLLEGE OF PHYSICIANS—NESTOR TIRARD ON GLYCOSURIA AND GANGRENE—ROYAL SOCIETY OF MEDICINE—NEW NATIONAL COUNCIL—OBITUARY.

London, November 21, 1914

This year's Bradshaw lecture at the Royal College of Physicians cannot fail to delight clinical observers. Dr. Nestor Tirard took for his subject the study of glycosuria, illustrating it by some careful clinical contributions of considerable importance. But these constitute when looked at as a whole a powerful appeal to reinstate clinical research in the position from which it has been somewhat lowered by the devotion of so many laborers to laboratory work. Not that he undervalued pathology or bacteriology, but found glycosuria is encountered under too many varying conditions for it to be due to one constant lesion. Atrophy of the pancreas has been the most frequently observed, but is by no means constant, only 13 out of 27 cases examined by Saundby showing it, all the others having the organ enlarged, congested, or normal. Dr. Tirard regards glycosuria as a perversion of a natural physiological process which might be compared with the perverted growth of natural cells seen in cancer. But we cannot expect to trace these causes of perversion at the post mortem. Lesions may be found if the perversion has been long continued, but not definite, as various organs may be altered without being the result of the glycosuria. The rapidity of the termination may leave all parts wasted alike.

The lecturer then drew attention to a series of graphic records from charts he had constructed and employed for years to show daily the total quantity of sugar (estimated from a mixed specimen of known volume). They also show the amount of liquid taken and passed, the sugar grains per ounce, and other items. The charts confirmed previous knowledge and indicated distinctions between diabetes in the aged and the young, etc.

The relative influence of diet and drugs was next considered. Of the latter, codeine, which has been used by many, did not give very obvious or constant results. Sodium salicylate or acetylsalicylic acid gave more satisfaction. In a case in which the glucose had been reduced by dieting it disappeared under the drug and this benefit continued when a moderate amount of carbohydrate was allowed. For a time bread was at once followed by reappearance of glucose, but at length two ounces could be taken after the salicylate was left off.

To the salicylate the lecturer often added two or three times as much bicarbonate of sodium, according to the degree of acidity or tendency to drowsiness or other toxic symptoms. He also made free use of laxatives, especially salines in moderate doses, but he had also tried the large doses lately recommended in urgent cases for two or three days in succession.

The relations between sugar and loss of weight and also of urea and points of prognosis having been noticed, Dr. Tirard came to the most interesting suggestion of his lecture—the relation of glycosuria to gangrene. He seems first to have been impressed by some grave cases of glycosuria sent to the medical from the surgical wards as unfit for operation with so much sugar passing. All seemed very severe and yet all recovered rapidly, all had some form of suppuration or gangrene. It has been previously observed that gangrene and glycosuria have occurred together and that more than once, though it was not suggested that they were interdependent. Searching his records, Dr. Tirard was surprised to find how often patients had mentioned some suppurative attack as preceding the glycosuria, and how often, too, clinical clerks had recorded such statements without a thought of their possible importance. Having further learned the value of early removal of pent-up pus, or of gangrenous tissues, he asked, can we not go a step further and add another theory of glycosuria knitting together in a new light the results of clinical observation, physiology, and pathology? Of drugs the most useful, the salicylates, are those we credit with most power over toxic processes due to microorganisms. By removing sloughing tissues and gangrene we find glycosuria quickly reduced and some cases seem due to pancreatic perversion and toxic absorption. If so, might a vaccine counteract the toxic influence?

A National Council for Combating Venereal Diseases was inaugurated last week. The movement originated with Major Leonard Darwin, President of the Eugenics Education Society, who applied to the President of the Royal College of Surgeons for cooperation. He agreed, and enlisted the presidents of the Sister College and the Royal Society of Medicine. A strong committee was formed who communicated with the Royal Commission on the subject. They extended the proposals so as to embrace the question of popular instruction, especially for the poor, on the dangers of ignorance and recklessness.

The new council will aim at providing accurate information, facilities for treatment, more opportunities of study for students and practitioners, cooperation with existing associations and in connection with them organizing and supervising lectures and literature. Finally, the council will promote such legislative, social and administrative reforms as are relevant to the above stated aims.

The Registrar-General in the supplement to his report this year, for the first time tabulates the marital condition of females. In the earlier years of married life wives have a heavier mortality than spinsters. But from about 45 to 55 the position is reversed and later on there is not much difference. All through life until old age the rate of mortality of widows is high. Above 80 there is scarcely any distinction between the three classes—single, married and widowed.

On Wednesday another medical research expedition—the 32d—set out from the Liverpool School of Tropical Medicine. This is bound for Sierra Leone to investigate the biting insects associated with the tropical diseases of the colony. The members of this expedition are Professor (of Parasitology in the Liverpool University) Warrington Yorke and Dr. Blacklock, Director of the Runcorn Research Laboratory. They are empowered to provisionally select a site for a laboratory which is to be established to unify the study of diseases, under the will of Sir Alfred Jones.

The Royal Portsmouth Hospital has now received the radium purchased for it by public subscription for £2,000, and the radium department is established.

Dr. Eustace Smith, Physician to the East London Hospital for Children, and Consulting Physician of the City Hospital for Diseases of the Chest, died November 14, in his 80th year. He was appointed a Chevalier of the Order of Leopold by the late King of the Belgians, to whom he was a physician. He took the M.D., London, in 1865; was elected F.R.C.P. in 1874, and later served a term on the Council of the College. You well know his "Practical Treatise on Diseases of Children," it being generally regarded as a valuable statement of the subject up to the date of each edition—several having been called for.

PARIS IN WARTIME.

To the Editor of the Medical Record:

Sir:—About the middle of the fifth century, when the fierce Attila and his Huns were threatening Paris, a woman by the name of Geneviève, who had previously warned the inhabitants that this danger would come upon them, now exhorted them to hold fast in their islands in the river and in this way escape the peril. This they did; the woman was subsequently canonized at Ste. Geneviève and became the patron saint of Paris; and the Pantheon, on the Montagne Ste. Geneviève, was erected in her honor. During the Revolution, however, her remains were burnt and scattered to the winds; but some of her relics, with her tombstone, were piously gathered together by the faithful and preserved in the adjacent church of St. Etienne du Mont, where they have since continued to be objects of veneration.

In view of our recent escape from our enemies I had the curiosity to cross over to St. Etienne the other day to see whether anything unusual was going on at Ste. Geneviève's tomb. To my way of thinking, St. Etienne is the most interesting and picturesque church in Paris, both historically, architecturally, and on account of its very fine old stained glass, I always look in there when I am in the Latin Quarter, and time only strengthens my opinion of the beauty of this edifice. And, sure enough, the devout had been equally conscious of the narrow escape they had just had, for the saint's catafalque had been opened, presumably exposing the relics to view, her chapel was blazing with a host of votive candles, a priest was holding service, and about him, out in the choir-ambulatory, and behind the catafalque in the adjoining chapel, was a large body of worshipers whose attitude was singularly different from that of the congregations one ordinarily sees in these churches. It was a very striking sight, and I stood in the semi-darkness back on the other side of the church and watched it for quite a while. There is little doubt but that the venerable saint did us an uncommonly good turn in the early days of last September!

I paused as I left the building to take a last look at its wonderful old glass windows; one never knows, in these times. It was only last spring that I was at Rheims, whose magnificent and absolutely priceless glass now lies in a million fragments; any one who has seen the afternoon sun stream the length of the Rheims nave through that marvelous west orange window will realize a small part of the havoc wrought. There was nothing in the world to equal the Rheims stained glass, the nearest approach, though from afar, being that of the cathedral at Tours. Quite recently one of the enemy's aeroplanes also contrived to drop a bomb on Notre Dame de Paris, though fortunately the damage done was insignificant, a slight tear in the roofing, I believe. If they had succeeded in getting it through into the transept, the two famous and superb rose windows would naturally have been blown to atoms, and one of the chief glories of Paris would have perished.

This war has made many a strange and unexpected victim, and will undoubtedly continue to do so; but among them few seem more deserving of sympathy than the nurses, now quite a number, who have succumbed to septic infection while caring for the badly wounded soldiers. Not only are pus-fingers followed by fatal, generalized septicemia, but this can occur from a single deep prick of the finger without local abscess; and among the different agents through which this is brought about, it seems that the common safety-pin is one of the most dangerous. Such a pin is taken from a septic bandage, laid aside, inadvertently used again, and the nurse pricks her finger in inserting it. In these times, when septicity is so rampant that the whole trend of surgery has had to be changed, asepsis given up, and a return made to the antiseptic practices which had long disappeared, too much care cannot be taken in the handling of pointed instruments and in the protection of even the smallest solutions of continuity of the face or hands. To succumb to generalized septicemia through the careless management of a safety-pin is a tragedy of the first magnitude.

From a medical point of view the present conflict will probably be known in the future as the tincture of iodine war. At any rate on this side of the affair all of the wounds are being dressed in this manner, and the consumption of this preparation must be something enormous. But how slowly the human mind does act! Years before this war everybody's opinion was made up here as to the efficacy of tincture of iodine in the treatment of wounds; everybody was equally convinced of the truth of the venerable adage that preventive action is the only one that counts in medicine. Yet not only were all the individual emergency dressing packages prepared for the army without any tincture of iodine to apply to the wounds, but it has taken the authorities three months of actual hostilities to evolve the idea that it might be well to

supply each soldier with a very small sealed tube of tincture of iodine for use *before* he applies his dressing to his wound! However, this is now being done in all haste, and it is hoped that before long this precaution, combined with better attention to the wounded at the closest evacuation bases, will tend to diminish this appalling array of cases of tetanus and gas gangrene that has thrown a maleficent shadow over the wards of our ambulances. During a recent tour of inspection one of our surgeons says that he saw well over a hundred cases of tetanus! Since touching on this subject in a former letter, two other statistics have come to my notice; in one of the R. A. M. C. ambulances at Rouen they saved two cases of tetanus out of twelve, the two being tardy, mild cases; but Doyen of Paris who treats this disorder by intraspinal injections of first 60 c.c. of serum, and two days later, 40 c.c., the patients being then tilted backwards at an angle of 45°, on the supposition that the serum is going to filter upward toward the nerve centers, claims to have lost only three out of twenty-four! This is such an utterly different tale from *all* of the other statistics that one is somewhat perplexed; it would mean a mortality of only about 12 per cent., whereas all of the other surgeons report 80-90 per cent.!

The other substance that has been used on a very large scale during this war is peroxide of hydrogen; most of these vicious germs being anaerobic, the line of action has been to open up all bad foci, clear out fragments, clots, foreign bodies, etc., and then drop in peroxide. What the patients' impression of this process is like can perhaps be gathered from the remark made by one of them to his nurse during a dressing: "Sister, I am not going to look at what he is doing; but just give me warning when he is about to drop in the *tabasco sauce!*" A surgeon of my acquaintance tells me that he cured a bad case of gas gangrene in a Morocco negro by driving a tube beneath the skin and under the fasciæ and pumping the patient full of oxygen gas,—keeping this up for sixty hours!

An immense advance in the ambulance of today over that of former wars is the absence of all smell of antiseptics. Those who remember the sickening odor of phenol, combined with that abomination, iodoform, will appreciate the clean, fresh atmosphere of the wards of our times.

C. K. AUSTIN, M.D.

PARIS, November 14, 1914.

OUR LETTER FROM THE PHILIPPINES.

(From Our Special Correspondent.)

MEETING OF THE PHILIPPINE ISLANDS MEDICAL ASSOCIATION—HOSPITAL CAR OF THE HEALTH BUREAU—HEALTH CONDITIONS AMONG THE "REMONTADOS"—ISOLATION OF CHOLERA CARRIERS—MAJOR MUNSON ADVISORY HEALTH OFFICER—EXPECTED RETURN OF DR. HEISER—SOCIAL CENTERS IN MANILA AND THE PROVINCES.

MANILA, October 20, 1914

THE annual meeting of the Philippine Islands Medical Society will be held in Manila on November 4, 5, 6, and 7, in the College of Medicine and Surgery. The officers of the Society are: President, Dr. N. M. Saleeby; vice-president, Dr. A. G. Sism; secretary, Dr. R. B. Gibson. The Councillors are Drs. Victor G. Heiser, W. E. Musgrave, Benito Valdes, M. W. Ireland, and Ferdinand Schmitter. The committee having the arrangements in charge was composed of Dr. S. C. Gurney, chairman; Drs. H. D. Kneedler, P. K. Gilman, A. G. Sison, and R. M. Thomburgh.

The hospital car of the Bureau of Health, loaned by the Manila Railway Company, has just been finished and should shortly be put into operation. It is painted very attractively in white and gold and will shortly be sent into the field with a sanitary exhibit, moving picture outfit, and native lecturers. There will be a small museum of apparatus and appliances needed in the provinces, models, photographs, and charts. It is expected to carry the gospel of health and cleanliness wherever the railroad penetrates.

The Secretary of the Interior recently organized a party to inspect and examine into the condition of a number of "remontados" or semi-wild people of the mountains who had appealed for government aid. Many had lived on the mountainous area of the Manila water shed, and had been removed therefrom to prevent any water pollution. Sickness, locusts, and drought had reduced them to extremities, and they came in to San Mateo, about an hour by automobile from Manila, coming in from their mountain retreats. They proved to be a physically weak, small, and degenerate outfit, infected with malaria, hookworm, skin disease, and tuberculosis. They had a prognathous facial angle quite different from that of the coastal Filipino, wavy hair, and frail physique. The Government gave them rice, clothes, quinine, etc., and is to settle them on government land in the foothills and provide seeds, farming implements, and instructors in their use. They own no carabao or stock, and many are so backward that their only farming implement is a bolo. About a hundred of them came down, and another hundred ventured near the town, but took to the hills when someone told them of the European war and said that they would be liable to be drafted therein. Their numbers in the mountains back of Manila are variously estimated, with a maximum of about three thousand. Their death rate is high, and there is little if any increase among them.

Hospitalization of cholera carriers has been finally accepted by the native press and people as a necessary factor in cholera control, though two or three months ago it looked as if serious opposition was developing which would prevent its employment. Cholera in Manila has now been brought down almost to the vanishing point, and the chief factor has undoubtedly been the detection and isolation of cholera carriers. So far, over 600 have been found and held until cleared up, and nearly 2000 examinations are being made daily.

It appears that Major E. L. Munson, Surgeon, U. S. Army, who was offered the appointment as acting Director of Health, declined to accept it, but has been assisting the government in an advisory capacity only. Dr. de Jesus, the assistant director, has been the executive head of the bureau, while Major Munson has given advice as to policies and methods. The arrangement is new to the Philippines, but is much like that of the "Residents" which the British and Dutch maintain in India, Java, etc., for the assistance of native authorities.

It is reported here that Dr. V. G. Heiser, the Director of Health, will probably return from leave of absence early in December. The papers state that several flattering offers have been made to him to undertake health work in the United States. Certainly the results which he has achieved have warranted the belief that he could successfully handle sanitary problems anywhere, after surmounting the difficulties here.

The papers are having a good deal to say about the "social centers" which are being established in Manila and in various parts of the provinces. While these are common in many parts of the United States, they are new to the Philippine Islands, where they should prove very successful. Various government bureaus are cooperating, with the support of outside individuals and organizations. The usual unit is established in a school building, where there are facilities for reading, lectures, social entertainments, etc. A library is established in the school building, and the school playground made available to others than scholars at certain times. A school garden is conducted for demonstration and educational purposes by the Bureau of Agriculture. Nearby the Bureau of Health conducts a dispensary and clinic and the municipal doctor examines school children. The Mother's League maintains a maternity and visiting nurse, and supplies nursery accessories and infant and other food to mothers unable to pay for them. The Antituberculosis Society also maintains in cooperation with this social center its visiting nurse, and supplies, food and supplies, without charge to the indigent. Much emphasis in an educational way is being laid upon health matters, and these establishments should soon exert a profound effect on the betterment of public health and welfare.

8. The Shaft of the Radius as a Pin Cushion. H. F. R. Watts.

2. The Mortality after Prostatectomy.—A. L. Chute believes that the high mortality following prostatectomy is unnecessary and is to be avoided in two ways: First, by getting kidneys that are not doing their work into a condition where they are acting efficiently; and, second, by avoiding injury to embarrassed or susceptible kidneys at the time of operation. The question of the mortality hinges almost wholly upon the condition of the kidneys, or perhaps upon the functioning of the kidneys. The task of getting them into condition must be done before operation. A certain amount can be done after operation, but for the most part whether or not a patient is going to recover has been decided before one begins a prostatectomy and depends upon the renal function.

3. Magnesium Sulphate in Streptococcic Meningitis.—W. S. Bryant reports a case of this condition in a man aged 22 years, complicating acute otitis media. The diagnosis of cerebrospinal meningitis was established by the symptoms and lumbar puncture. A decompression operation gave immediate relief from intracranial pressure. The toxemia was combated by magnesium sulphate water and drainage. A cure of the cerebrospinal meningitis followed in a few days. Infection of the cranial wound resulted from contamination of the dressings. The result was a recurrence of the toxemia together with encephalitis, with death on the 190th day from time of the decompression operation. The cause of death was encephalitis and toxemia and not cerebrospinal meningitis.

4. The Modern Treatment of Amebic Dysentery.—E. F. Haines concludes on the basis of the treatment of four cases of amebic dysentery that emetine acts well in chronic cases of this condition and that in these it shows its most wonderful therapeutic action. Some have objected to emetine on account of the relapses that have occurred. It seems that the entamebas that are not killed or driven out of the intestinal tract during emetine treatment are stimulated to encystment and thus rendered harmless to their host. However, the cases that continue to harbor the entameba in an encysted form are carriers of the disease, and thus are a danger to the public health. It would seem, therefore, that in order to complete the treatment of amebic dysentery, some form of irrigations should be used. Quinine irrigations have proved of value in the treatment of amebic dysentery, and it seems as if their use in conjunction with emetine would reduce the number of carriers of this disease. Before condemning emetine as a potent factor in the treatment of dysentery, one should make sure of the causative organism, for in the bacillary form of dysentery emetine is useless.

5. Intestinal Putrefaction with Convulsions.—W. L. Thompson reports the case of a six-year-old boy who at the age of two years, while in apparently good mental and physical condition, began to have attacks of dizziness in which he would stagger and sometimes fall. These attacks occurred at first only during waking hours, increasing in severity until the typical symptom-complex was established. Spasmodic movements of the arms and legs were accompanied by congestion of the face, gurgling expiration through clenched teeth, and rigidity of the neck and body. The child occasionally fell to the floor but never lost consciousness. The duration of each seizure was very short. The attacks gradually increased in frequency, varying from 10 to 50 in the course of twenty-four hours. Night attacks, during which the parents were awakened by the child's stertorous breathing, were common, but of short duration. The salient features of this case were as follows: (1) The great number (50) of the convulsions per diem; their mild character; their brief individual duration (1 to 2 minutes); their occurrence for three consecutive years. (2) The preservation of unusually sound mental and physical health. (3) The rapidity and the completeness of the cure following thorough sterilization of the intestinal tract. (4) The preservation of the sterility thus obtained by acclimatization of the lactic-acid bacillus. (5) Confirmation of Metchnikoff's contention that the large intestine, by reason of putrefactive processes occurring there, is the chief portal of entry to the system of profoundly toxic substances.

1. Phlegmons of the Upper Respiratory Tract.—J. O. Roe from a study of these phlegmons in their various relations reaches the conclusion that the virulence of the disease depends more largely upon the condition of the patient—that is, the soil in which the germ becomes implanted—than upon the strain or character of the germ, the activity of the germ de-

pending upon the condition that quickens it into activity, which may be local or general or both. Chronic affection of the throat may provide in many cases the inviting condition for the activities of wandering germs. Farmers and fanciers recognize the importance of introducing new strains in order to increase the vigor and productiveness of their animals; so may it be that the introduction of a new strain of streptococci into the old saprophytes starts a new and prodigious activity. Davis in a bacteriological study of chronically diseased tonsils and their relation to arthritis, nephritis, and endocarditis, almost invariably found in the crypts large quantities of virulent hemolytic streptococci fatal to guinea-pigs and rabbits, with joint and other manifestations. These germs were ever ready to take on an active form of existence when excited to activity by external influences or given a chance by the weakening of the defenses of their host.

2. **Intestinal Stasis.**—B. Robinson holds that the old methods of treating obstinate constipation are better than the new and is not convinced that the use of purified mineral oils by the mouth is any advance over the well-known and approved olive oil by enema. Indeed, the purest California olive oil only contains one-fifth of one per cent. fatty acids and is shown to be a very poor culture medium. Taken, therefore, by the mouth it is quite as innocuous as the nonabsorbable mineral oil. Moreover, it has a very decided advantage in that it promotes healthy nutrition, as well as being an equally good intestinal lubricant. The former quality the mineral oil does not possess. When properly given, *i.e.* small doses to begin with after meals, it does not occasion dyspeptic symptoms which cannot be readily neutralized with a little pancreatic extract as an emulsifier. Finally, good olive oil promotes intestinal peristalsis and thus prevents bowel stasis with its sequelæ. This action is obtained when olive oil is used both by the mouth and rectum, and usually it may be employed advantageously at the same time for a while at both ends of the digestive tube.

4. **Sciatic Pains.**—A. M. Forbes states that in the majority of patients suffering from sciatic pains a primary lesion may be found in the spine or sacroiliac joints. This lesion is of a so-called rheumatoid nature, amenable to treatment.

6. **Parageusia and Its Treatment.**—By T. F. Reilly. (See MEDICAL RECORD, September 5, 1914, page 438.)

8. **Postpartum Hemorrhage and the Treatment.**—J. Gardiner states that in the treatment of postpartum hemorrhage, the first factor of importance is to control the bleeding. The patient should be placed in the Trendelenburg position, and the abdominal aorta compressed either digitally or mechanically. If the hemorrhage is from the uterus, that organ should be stimulated by massage and irrigated by hot intrauterine douches of dilute acetic acid or iodine solution. If the uterus does not contract, it must be packed with sterile gauze from the roof of the uterine cavity, layer by layer, through the cervical canal and the vagina. Chrolak issues a warning that a tampon inefficiently applied is often the cause of a fatal issue. It is convenient to use strips of folded gauze, two inches wide and five yards in length, on which tape has been sewn, long enough to extend outside of the vagina. The tape assists in the removal of the gauze. An abdominal binder should be applied to keep up the intraabdominal pressure. A good binder is a proper sized huckaback towel. It is firm and strong and can be pinned to fit the contour of the hips and abdomen. An abdominal compress, sand bag or shot bag, may be used. The parametrium in hemorrhage may be clamped from the uterus or cervix. The two medicinal remedies for this condition which stand out preeminently above all others are ergot or its derivatives and pituitary extract. The latter, while it has proved not to be an obstetrical panacea, has a definite limited use in postpartum hemorrhage. When the hemorrhage occurs, even though pituitary extract has been used, the dose should be repeated, as repetition of the dose in no wise injures the mother. In cases of severe hemorrhage, it has been used intravenously with splendid results. The majority of writers advise the use of pituitary extract in combination with some form of ergot. The contraindications are advanced cardiac disease and arteriosclerosis.

2. **Genetic Factors in Psychoneurosis.**—D. Gregg presents the following conclusions drawn from the analysis of 100 cases of psychoneurosis: In the majority if not in all cases of psychoneurosis there exists an essential factor, namely, a natural psychopathic tendency, hereditary or acquired in fetal life. If the age at which symptoms occur among psychoneurotic individuals may be considered an index of the potency of the essential factor at work, leutic, insane, neurotic, and alcoholic defects among forebears are of importance in the order named in the production of psychopathic tendencies. Among psychoneurotic individuals, somatic difficulties tend to induce symptoms earlier than do difficulties of environment. The longer a psychoneurosis exists, the more numerous will the symptoms probably be. Prophylaxis against the psychoneuroses can be furthered by early diagnosis, and by the elimination of the provocative agents of somatic and environmental difficulties with the aid of medical treatment, psychoanalysis, and psychotherapy, but no prophylaxis can be effective that fails to consider the essential factors in the production of the psychoneuroses.

4. **Efficiency of Sodium Chloride in the Therapeutics of Bright's Disease.**—By H. Lowenburg. (See MEDICAL RECORD, July 4, 1914.

5. **Reduction of Prostatectomy Mortality.**—B. A.

Thomas states that the most appropriate method of prostatectomy in a given case depends on the pathological condition present, rather than on the normal anatomical relationship of the prostate. This pathological condition is of greater consideration than the statistical low mortality-rate of either the perineal or suprapubic method, and more discrimination in this respect offers a means of shaving even the present low percentage. The cystoscope is a most important aid in the determination of the avenue of approach in the particular case. Although the renal function is the paramount consideration in determining the operability of a case, consideration of other organic conditions must never be slighted. Indigocarmine is superseded by no other kidney test in the estimation of the renal function. Apparently of more dependence than merely the onset and quantity of excretion of indigocarmine is the index of elimination, described by me. The reduction of the mortality following prostatectomy to 3.3 per cent. is attributed largely to cystoscopical aid in determining the method of operation, and also to the index of elimination of indigocarmine in discrimination as to the operability of cases.

7. Direct Method of Intralaryngeal Operation.—C. Jackson concludes that the direct method is the only one by which the larynx in children can be operated upon. The indirect or mirror method is applicable only to adults. The reversal of the image sagittally, without reversal laterally, compels the operator to develop the ability to move his forceps backward when the image appears to require the forward direction; and, more difficut still, is the necessity to combine for diagonal movement a reversed anteroposterior with a true lateral movement. The difficulties to be surmounted by the direct method of intralaryngeal operation require prolonged and constant practice, but not nearly to the same extent as required by the mirror method. No anesthetic, general or local, is necessary for operations on the larynx in children. In them, cocaine is dangerous in any case, and general anesthesia is absolutely contraindicated in all cases with even the slightest degree of larynx stenosis. Local anesthesia should be used in adults, general anesthesia, preferably with ether, being required only when cocaine is contraindicated or when the ischemic accompanying its use causes the growth to shrink to such an extent as to hinder accurate removal. No one method can be said to be best for all cases and all operators. The laryngologist should try all methods and instruments so that he may decide for himself what best suits his personal equation and he should then be fully prepared to use the method which, in his hands, is best adapted to the particular case.

15. Prevention of Communicable Diseases in General Hospitals.—D. L. Richardson notes that infectious diseases are introduced into the hospital chiefly by new patients. Well-equipped and well-managed isolation wards should be provided for all suspicious and infectious cases and for all children under 14 years during a detention period. There should be very careful admission of all patients, nurses, and help, and supervision of the same. There should be sufficient equipment for all wards and better teaching of nurses and help about infectious diseases.

16. Chenopodium in Hookworm Infections.—R. L. Levy finds that oil of chenopodium is an effective vermifuge in the treatment of uncinariasis. It is not unpleasant to take, its ingestion is followed by no disagreeable symptoms, and it is cheap. In therapeutic doses it is non-toxic. Oil of chenopodium, he thinks, deserves a most thorough trial in the campaign against hookworm disease.

1. The Treatment of Wounds in War.—Sir W. Watson Cheyne describes his method of disinfection of wounds as follows: The patient having been placed under an anesthetic, the first thing is to control the bleeding. In the case of an extremity a tourniquet is applied, but where the wound is situated in the trunk any visible bleeding points should be clamped and the wound temporarily stuffed with gauze or large sponges. The next step is to cleanse and disinfect the skin thoroughly. In the first place scrub it thoroughly with 1 in 20 carbolic lotion and ether soap, then shave it, and finally wash it thoroughly again with the carbolic lotion, leaving a cloth saturated with the lotion over the whole area, so as to continue the disinfecting action and protect the skin while the interior of the wound is being attended to. The interior of the wound must now be disinfected, and if it is necessary to gain access to the deeper parts in order to enable one to see what one is doing, which is very important, the wound must be sufficiently enlarged by incisions made in suitable directions.

The blood must be thoroughly swabbed out, the wound made as dry as possible, and the skin or fat or other structures which are visibly soiled with earth or dirt should be cut away. The wound being then held wide open by retractors, a piece of sponge dipped in the liquefied carbolic acid is carefully and thoroughly applied to the whole surface of the wound and to all the recesses, care being taken, by holding a swab in the other hand on the edge of the wound, to prevent the acid running over the skin. It is well to sponge out the wound after the first application, and then to apply the acid a second and even a third time if there is bad soiling.

If at the bottom of the wound there is a long narrow track leading to the tissues, it may not be necessary to disinfect it along its whole length, because the probability is that the bullet or fragment of shell does not carry the organisms in to a very great depth. If it is a large wound which has to be soaked with the undiluted carbolic acid, it may be well, after about five to ten minutes, to wash it out first with 1-20 carbolic lotion and then copiously with saline solution, so as to get rid of the excess of carbolic acid and thus reduce the chance of absorption. The author advocates the use of antiseptics at the very commencement of the treatment, but at that time, in order to serve the purpose, they must be sufficiently powerful. The author is much opposed to their use in suppurating wounds. Some object to the use of those strong antiseptics on the ground that they may cause a slough. This, however, is a mistake; used as the author advises they may kill a miscroscopic layer of the surface of the wound, but they cause no visible slough. Even if they did cause a slough, however, if one has absolutely destroyed the bacteria the slough is of no material consequence; it will be absorbed like any other piece of dead tissue, and a slough, the author maintains, is of little consequence as compared with the life and future usefulness of the patient.

1. The Treatment of Wounds in War. W. W. Cheyne.
2. The Principles of Wound Treatment as Established by Lister and the Subsequent Modification in Treatment. F. M. Caird.
3. The Borderland of Disease. G. Rankin.

2. Wound Treatment as Established by Lister.—F. M. Caird points out that in so far as septic prophylaxis is concerned an antiseptic method has given way to an aseptic. Antiseptics remain still essential for the cleansing of the skin; boiled water and sterile dressings accomplish all else. Provided one exclude all causes of putrefaction from the tissues, "all they need is to be left alone." Lister's ideal has been realized; the surgeon is master of the wounds he has himself inflicted. One must, however, note that the pendulum of fashion may have swung a little too far in the direction of aseptic surgery. This has led some surgeons who have forgotten the value of the older methods to abandon the succeeding prolonged laborious washing and scrubbing of the integument, and to substitute therefor the use of tincture of iodine as the most convenient and serviceable antiseptic for this purpose. They may have good reasons for adopting such a plan; it does not, however, seem to be the best agent for the purification of wounds.

3. The Borderland of Disease.—G. Rankin in concluding his article on this subject ventures the belief that there is perhaps almost no such thing as "perfect" health, but it is possible by careful inquiry and patient investigation to make sure that one does not find a firm opinion upon a casual observance of physical signs or a mere negation of subjective symptoms. It would be a provident and wise plan if every man went to his doctor for a thorough overhaul once in six months, not because he is driven to him on account of feeling ill, but because he is led to him by the desire to keep well. It is true that physicians are more frequently consulted about trivial ailments than on account of acute and serious disorders; nay more, their time is often vexatiously encroached upon by having to listen to a long tale of imaginary woes and a formidable recital of pains for which one can find no physical explanation, but, if the author's contention is right, all such patients are on the borderland of disease. Their discomforts, whether physical, mental, or emotional, have a foundation in fact somewhere, and clearly point to a fault that disturbs the harmony of perfect physiological activity. The engine is not tuned up to the best work it is capable of, and unless adjusted in time, some part must inevitably become permanently faulty, and constitute the blemish which spells premature consignment to the human scrap-heap. "Prevention is better than cure" is truer today than ever before, and physicians will do much to justify the proverb and to hasten its full realization if they direct their attention more and more to the borderland country and the evidences which are constantly to be found there of the earliest movements on the part of the enemy of mankind.

Treatment of Tetanus.—Weintraud and Unger each make contributions to this subject. The latter relates a case of moderately severe tetanus in which he injected 20 c.c. antitoxin directly into the arch of the aorta (through the internal carotid). Slight improvement followed and on the following day an intravenous injection of 100 serum units was made. In 48 hours from the aortic injection there was almost complete muscular relaxation. In the use of Meltzer's method he suggests as a result of animal experiments that a catheter be introduced through a minimal tracheotomy wound as far as the bifurcation and connected with an oxygen bomb. With this precaution it should be possible to use large doses of magnesium sulphate. Weintraud's article is an exhaustive one especially in its review of the magnesium method of Meltzer. The mortality of the disease despite the several innovations in treatment is at present high. In one small Wiesbaden series of 8 cases but 3 were saved and these by the use of magnesium. In Limburg in another series of 8 cases but one patient was saved. In a third series of 8 cases at Weilburg but two ended favorably. No details of treatment are mentioned, save as above. The army tetanus which is now so much in evidence partakes somewhat of the nature of an epidemic, such at least as occasionally occur in lying-in institutions in both mothers and infants. Many cases are atypical. Some seem harmless at the outset—a little stiffness in a limb or muscular twitching. In civil practice with sporadic incidence this local tetanus seems unknown to the ordinary practitioner who if he sees it fails to recognize its nature. Other early and usually overlooked symptoms are profuse sweats, vertigo, difficult urination. The sore face, stiff neck, and especially certain pains in the chest which suggest pleurisy are only too frequently misinterpreted. When the victim suddenly becomes completely rigid the nature of the condition flashes across the mind of the medical man and he sends at once for antitoxin. It is not yet too late to profit somewhat by the latter if it us used in large dosage and is given in part by the intralumbal method. But serotherapy is not sufficient alone save as a prophylactic. There must be something to quiet the muscular excitability. The narcotics which have been used merely as palliatives have not infrequently saved life. The author now reaches the subject of the magnesium therapy. Magnesium sulphate has shown itself in animal experiment the ideal narcotic in tetanus, and although this discovery was made eight years ago the great majority of practitioners have not yet begun to realize that so familiar a drug can exert such power over a disease like tetanus. In regard to its use in mankind over 50 cases have been reported. Stadler, an associate of the authors, has determined that the mortality thus far under magnesium treatment is but 35 per cent. Kocher lost but one patient out of six thus treated. Yet the technique of its exhibition is by no means yet perfected. The author would give antitoxin if the case is seen in its inception, repeat its use and also give it intralumbally, but would associate with it the magnesium treatment, if necessary by the cord; and also make free use of the old narcotics and sedatives.

Food of the Worker and the Principles of Nutrition.—Hirschfeld sums up an article on some recent studies of this subject as follows: the need of a high protein fraction in the daily nutriment has not been shown. The protein requirement will be fully covered by an amount sufficient to make up the daily waste. In sound, healthy subjects under favorable external conditions, small quantities of meat will suffice, but one should not renounce its use entirely for even the poorest people miss the deprivation keenly. If the workers are not in good health and somewhat broken down physically, and have to perform hard muscular labor they should receive meat in abundance and refrain from eating too much bulky vegetable matter, especially if they have not been accustomed to this diet of vegetable foods the potato is unsurpassed. It is cheap, readily digestible and well utilized in the intestine. It is also very favorable for fat addition and may be made to serve as a breadstuff. Prisoners were once believed to suffer because of a

meat poor diet. It has, however, been possible to overcome the supposed deficiency symptoms without any increase of meat in the ration—by greater variety, greater concentration, by adapting the calories to the patient's necessities, by the use of relishes, etc.

Münchener medizinische Wochenschrift.

October 6, 1914.

Practical Viewpoints in the Tetanus Problem.—Kreuter of Erlangen begins with the truism that tetanus is a most dreaded form of wound infection. In times of peace its incidence is sporadic. In warfare, its occurrence is massed—every hospital furnishing its quota of cases. With its high mortality prophylaxis makes the first demand, and this is both local and general. The former may be summed up in the phrase "simplification of all wound conditions." There must be no recesses or diverticles and no foreign bodies to find shelter therein. In other words drainage must be ideal, a difficult task when the wounds are due to shell fragments and shrapnell bullets. Injuries which are followed by gas formation, etc., are ominous. Wounds made by horseshoes, however received, are dangerous. General prophylaxis is assured in large measure by serum injections, but the serum is very expensive. As the immunity conferred amounts to but two weeks on the average, prophylactic injections have to be timed properly, and must be given subcutaneously and in large dosage—100 units at least. We cannot always assume that the disease will fail entirely to develop. In cases of great natural virulence it is a therapeutic triumph to convert a malignant into a mild case by deferring its appearance and causing it to pursue a mild course. Is the disease preventable after its initial manifestations have developed? In the most malignant cases these do not tarry to develop. Dysphagia with no corresponding picture of angina is an initial symptom—perhaps one might term it a prodrome—which calls for a most energetic exhibition of serum. When trismus sets in there is no question of its nature—it is not a prodrome but an essential part of the disease. Yet it does not always set in, and in mild or deferred cases the initial tetanus may be confined to the muscles of the injured member. Cases with an incubation period of 8 or 10 days have a very bad prognosis, while if this period is over two weeks in length it is much more favorable, and serotherapy appears to give positive results. Treatment consists in the intravenous and intralumbal injection of serum. Intracerebral exhibition does more harm than good. Serum neutralizes the toxin but has no direct power over the conclusions. To antagonize these we may give in addition to morphine and chloral sulphate of magnesium, if necessary, under control of tracheal insufflation of oxygen. Baccelli's phenol method is powerless against severe tetanus in Austria and Germany. Although the author has seen much tetanus since the war began he does not draw upon his own experience, preferring to quote the dicta of special writers on the subject.

Bilateral Phrenicotomy for the Respiratory Spasms of Tetanus.—Jehn of Professor Saarbruch's clinic, Zürich, while not active in the war, writes a timely account of this new resource. After a series of animal experiments had shown that phrenicotomy paralyzed the diaphragm without serious consequences to the victim, the intervention was tested on an eight-year-old boy with tetanus. Of passing interest is the fact that a diagnosis of diphtheritic pharyngitis and laryngitis had been originally made. Soon the complete picture of tetanus had developed including a severe spasm of the diaphragm. In the course of a general spasm of the extensors the thorax was suddenly fixed in the maximal inspiratory position, while both the throat and abdominal muscles were rigid. The face was cyanosed as respiration became arrested. Consciousness was finally lost and three or four minutes expired before the seizure passed over. Sauerbruch now divided both phrenics behind the sternomastoid muscles. The patient then had numerous convulsions without dyspnea. Attacks of the latter returned, however, and were met by artifical respiration and inhalations of oxygen under pressure. As the patient on account of esophageal spasms was no longer able to take nourishment gastrostomy was performed. Patient made a slow recovery, having sustained thirty-five severe suffocating spasms. Phrenicotomy was of great benefit and did not interfere with expectoration, but seemed rather to favor it. By reason of the diaphragmatic paralysis the respiratory exchanges were found diminished on recovery and patient could only blow 200 c.cm. into the spirometer. His general health did not suffer as a consequence. The only drug received during the course of the tetanus appears to have been chloral.

Influence of Hypnosis on the Vegetative Centers.—Mohr considers first the temperature center. In a patient with purely hysterical or cerebral fever the temperature was brought to the normal and maintained there. The heat center had clearly been under the influence of cortical changes, which had been rendered null by psychotherapy. Next the author considers the secretion of gastric juice. In a patient with anacidity suggestion brought about a flow of gastric secretion. This should occasion no surprise because merely thinking of appetizing foods will produce the same result. The third case considered is that of coryza, which often possesses a nervous component. Since coryza depends largely upon a reflex mechanism we may speak of a "center" for colds, which is perhaps sensible to cortical changes. Kohnstamm believes that when atropine checks the oversecretion it acts in part upon this center.

Münchener medizinische Wochenschrift.

October 20, 1914.

Pulsus Irregularis Perpetuus.—Hering concludes a serial article on the rhythmical auricular tachysystole and pulsus irregularis perpetuus as follows: The two conditions differ to the extent that the latter is accompanied by auricular fibrillation. They have in common the so-called tachyerythism or increased stimulus frequency, the heterotopic origin of the stimulus, the disturbance of transconduction, the elective influence upon the latter of the vagus. The rhythmic auricular systole may pass over into the pulsus irregularis perpetuus, for example, under the influence of digitalis. When this occurs a presystolic murmur previously in evidence disappears. In auricular fibrillation the stimuli probably have a polytopic origin. It is influenced both by the vagus and accelerators, and is promoted by dyspnea (CO_2), dilatation of any segment of the heart, stenosis of the coronaries, certain poisons (digitalis, adrenalin) and certain alterations of saline concentration.

Treatment of Tetanus with Serous Transudate from the Abdominal Cavity.—Durlacher reports the following case which occurred at the Reserve Hospital at Ettlingen: On August 25 an officer was struck on the dorsum of the left foot with a fragment of shell which was extracted three days later. Meanwhile a cellulitis became apparent on the plantar surface. Two days later the parts were incised and given a dry dressing.

On September 3 the patient began to complain of stiff neck which was attributed to a draught. Two days later by reason of suspicion of tetanus he was isolated. In a few days more the entire picture of severe tetanus had developed. Not only was swallowing almost impossible but the respiratory muscles were badly tetanized. The temperature was not high. The only remedy mentioned at the outset is chloral in large doses. On the eleventh day of the disease some serous transudate was infused beneath the skin of the thigh and sudden relief was experienced. The infusion was repeated on the next day with the same result, although the first one seems to have caused a general and cutaneous reaction. Three infusions were given in three consecutive days and each was followed by pronounced relaxation in various muscle groups, although other groups appeared to be uninfluenced. The general impression was so decisive that no more infusions were given for several days. On September 21 only the abdominal muscles were still rigid. The patient received only chloral and bromides. On the 22d a fourth infusion was given as the tense abdominal muscles gave no sign of relaxation. General improvement followed and the patient's condition caused no further apprehension. The action of the transudate was specific in character. The latter was obtained from the peritoneal cavity of a patient with an uncompensated heart lesion, and was infused with as little delay as possible. It contained an abundance of lymphocytes and albumin. These should have undergone some breaking up in the patient's blood and the substances formed may have possessed antitoxic properties. This successful case may open up a new chapter in serotherapy. The author suggests that as dogs are somewhat refractory to tetanus canine serum is worth a trial.

Be Sparing in the Use of Cotton Dressing Materials!—Professor Williger warns the readers of the *Wochenschrift* of the great increase in the price of cotton and cotton goods. It has been advised to return to the use of charpie or lint, which, however, has been out of favor for many years. But the lint of 1870 was prepared under insanitary conditions. The author naïvely relates that his mother, assisted by the larger school girls, prepared lint in a dusty schoolroom. The cotton rags were collected from the villagers, were more or less soiled, the fingers of the girls were dirty, the lint was poorly packed and then shipped to France. Sterilization could have remedied these faults but it also would have destroyed the usefulness of the lint as a supple and absorbent dressing material. The author states that while we may have to come to lint in time there are at present materials which answer better. He is using jute to line splints, and in other situations in which cotton wadding is employed. Cellulose is a never-failing substitute for white cotton wherever the latter is used in large quantities. Cellulose, moss, cotton waste, etc., may be used for stuffing cushions and similar purposes.

Deutsche medizinische Wochenschrift.

October 8, 1914.

Von Behring on the Serotherapy of Tetanus.—That the Behring serum is able to cure tetanus is shown by the following case: A worker in the author's laboratory infected himself accidentally in the palm of the hand from a tetanus culture, a flask of the latter having broken with penetration of fragments of glass among the tendons. The wound at once received antiseptic treatment and an injection of antitoxin was made in the corresponding arm. The wound healed promptly but in four days after the injury a somewhat atypical tetanus appeared, certain isolated muscle groups showing rigidity (legs, shoulders, jaws, eyelids). The right axilla was now laid open, and the main nerve trunks isolated and infiltrated with the most powerful serum. The disease was at once and permanently arrested. The natural malignancy of the disease, which was not checked by the prompt injection of antitoxin, could be attributed to the dose of virulent culture received into the wound. The disease even if favorably modified showed a very short incubation period, while the general symptoms were of such a character that the prognosis had been very grave. The author now teaches that the tetanus toxin combines at once with the intramuscular nerve endings and while it cannot be neutralized in this combination it can still enter the blood, in which it should be exactly neutralized by intravenous and subcutaneous injections. To save life in these cases the so-called neural treatment as practised by the author, holds out the only hope. These injections do away with the need of resection of nerve trunks, but in cases in which serum is not available the question of a temporary resection of one or more trunks comes up very seriously. The reader is surprised to see little or no mention of the dried antitoxin as a wound dressing or of the intraspinal exhibition of the serum. Doubtless the teaching that nerve terminals are depots of infection will greatly modify future treatment.

Primary Lesion in the Rabbit from Inoculation with Pure Culture of Spirochetes.—Schereschewsky of von Behring's Institute, who was one of the first to make pure cultures of the spirochete, has succeeded in rabbit inoculations of the same. The microorganisms were obtained from a human papule and cultivated through seven generations. The culture was injected into the scrotal sac and parenchyma of the testicle. No primary reaction resulted and not until the forty-first day did a lesion appear, which evolved into a typical primary sclerosis. A second animal inoculated by scarifying the cornea developed parenchymatous keratitis at the end of thirty-three days. The inoculation experiments were carried out in a peculiar manner. The culture material was used four days after sowing, at a period too recent for the ordinary development of cultures. The author was at first working to ascertain at which period cultural virulence is the greatest. The positive outcome of the tests raises the question as to whether newly-proliferated spirochetes had actually been inoculated, or whether the transmission was due simply to the "seed" of the culture. The author excised the primary sclerosis from the scrotum of the rabbit, but a "chancre redux" at once developed in its site. The rabbit's semen was filled with spirochetes. Incidentally the author found that his cultures when kept in the incubator retained their virulence almost indefinitely.

Experiments with Abderhalden's Dialysis Procedure.—Otto and Blumenthal of Professor Loeffler's Institute have been testing the Abderhalden reaction with special reference to the diagnosis of pregnancy and to The behavior of precox patients towards testicular substance. The placental substratum was prepared with extreme care, but was broken up by sera of non-gravid women and by that of cancer patients. The test is very valuable to this extent that when it is negative pregnancy can be excluded with great probability. The test is almost always positive in the gravida, but the percentage of positives is equally high in cancer patients and positive finds are common in miscellaneous affections. A perfectly negative result appears to indicate freedom from disease in general, and from pregnancy in female subjects. The test is

not well suited for routine general practice. When the testes are used as substratum the serum of precox patients gives positive results in a very high percentage of cases. The same result is seen in the gravid, in manic-depressives and miscellaneous subjects in a sometimes high but very variable percentage. Precox serum breaks up placenta even more frequently than testicle. It therefore seems likely that in atypical or incipient precox positive finds with testes and placenta should possess considerable diagnostic significance. In a second brief article on the A. R. by Eder of Koblanck's clinic similar conclusions are reached. With a negative A. R. pregnancy can be excluded with the highest degree of probability. On the contrary, with positive A. R. we have to exclude at least the presence of cancer, syphilis, and suppurative processes before we can pronounce a woman pregnant.

Eye Lesions in Warfare.—Grounow writes for the benefit of surgeons in the dressing pavilions. Very common in soldiers is conjuctivitis from dust which should be treated with zinc sulphate solutions of ½ per cent. or borax 4 per cent. by instillation, twice daily. Compresses of 3 per cent. boric acid solution may also be used. As trachoma is common in Russia, prisoners from that country should be carefully examined, and, if necessary, isolated. The field surgeon should be able to differentiate between trachoma and simple granulated lids in adult patients. Simple foreign bodies in the conjunctival sac often require removal. Aside from these small responsibilities all other lesions should be cared for at the nearest field hospital, save for such first aid dressings as may be necessary. These comprise cleansing from foreign material and a first aid bandage.

Deutsche medizinische Wochenschrift.

October 22, 1914.

Morbidity from Marching.—Schuster first considers the seemingly insignificant condition characterized simply as foot soreness. This has, of course, a prophylaxis which consists in properly fitting socks and shoes. The device known as the "foot sparer" enables the soldier to wear a more roomy shoe, and he can use extra stockings in cold weather. The foot sparer also enables the soldier with falling instep to march without pain. The feet should, of course, be kept clean. Excessive perspiration should be kept down with salicylated talcum, and if necessary formalin in 10-20 per cent. solution. Salicylic acid plaster should be used for corns. A serious lesion once thought to be due to rupture of the transverse ligaments of the metatarsals has been shown by the *x*-rays to consist of actual fracture of these bones—usually the second metatarsal. The result of this injury is pressure pain and doughy swelling on the dorsum of the foot. In certain cases the bones do not break but undergo a periosteal thickening. These conditions often disable the soldier, sometimes permanently, as the condition may relapse as soon as he returns to the front. The foot sparer ought to be of prophylactic use, but much also depends on skill in marching on the efficiency plan of suppressing all unnecessary movements, and a proper employment of the rest periods. New recruits also suffer at times from tenosynovitis and periostitis. The former affects chiefly the tendons on the dorsum of the foot. If an effusion has not occurred the presence of the condition is betrayed by crepitus. If it has occurred the dorsum of the foot swells and there is inhibition of function. Periostitis develops on the upper third of the shin extending often from the knee to the middle of the bone. It appears as a painful swelling which pits on pressure. The victim is unable to plant his feet firmly. The condition is brought about by the large extensors of the foot which spring in part from the tibia, which become torn and distended with their own blood. Soldiers with either of these conditions require a few days bed rest with water compresses or iodine application to render them fit to walk. They should not, of course, participate in forced marches until they have completely recovered. The only other serious condition to which infantry troops are exposed is heat stroke and the author goes very minutely into this subject. Even in peace times the mortality from heat stroke is considerable and thousands perish annually from this cause alone. The troops march in the direct sunlight, heavily dressed, armed, and accoutered. No distinction can be made between an actual exposure to actinic rays and simple overheating. Humidity is a component, for as soon as this reaches 65 per cent. the danger is markedly increased. Absence of motion in the air adds to the risk. Before the stroke it is often noted that the soldiers cease to converse with animation and to sing. They stare fixedly, the countenance becomes dusty, individuals begin to drop and do not reply when interrogated. The men recall that they felt confused, saw spectra, felt palpitation, and precordial anxiety. The surgeon can do much when any of the prodromes are in evidence by calling a halt from time to time, allowing the men to unburden themselves and drink freely of cool water. Those exhausted by marching fall easy victims to heat stroke. The clinical picture varies greatly. Some soldiers do not lose consciousness, while others are comatose, convulsed (epileptoid), delirious, confused. Apparent recovery is often followed by fatal recurrence of symptoms. Aside from these cases death when it occurs does so within seven to nine hours. For recovery two weeks are required, but this does not mean restitutio ad integrum, because not only are there numerous reminders present in the shape of myalgia, prostration, insomnia, vertigo, headache, emaciation, bradycardia albuminuria, glycosuria, but definite sequelæ such as paralyses, neurasthenia, hysteria, epilepsy, psychoses, dementia (in some cases real or pseudoparesis). The simplest type of heat stroke is a mere swoon, to be managed as such. If the subject does not revive under this plan he should be treated with cold effusions; at times by venesection, saline infusion. To antagonize the dangers of heat stroke maneuvers and drilling should enable the authorities to weed out those specially predisposed. But these exercises are performed only in the cool of the day, and presumably after a night's rest, two conditions not realizable in actual war. Excesses of all kinds, notably in alcohol, can be inhibited in actual war. Flasks can be filled with cold coffee and tea. In daily water drinking too large quantities should not be taken at a time. Parades in hot city streets add to the risk of heat stroke.

True Bone in Sputum.—Kretschmer reports a case of this very rare phenomenon. The patient, a man of 31, brought to the clinic some pieces of spongy bone which he claimed to have expectorated. He was found to have a pleuritic effusion, probably an empyema. In the sputa were elastic fibers. A slight kyphosis was found, corresponding to the last two dorsal vertebræ. The patient continued to expectorate bone during the observation period. The first diagnosis was abscess of the lung with secondary erosion of the vertebræ, but this opinion was changed to a tuberculous abscess of the vertebræ with rupture of the same into the pulmonary tissue.—*Berliner klinische Wochenschrift.*

Insurance Medicine.

The Prognosis of Heart Disease, with Special Reference to Life Insurance.—Dr. Robert H. Babcock, Chicago, Ill., states that in determining the prognosis of any valve lesion something more is required than a mere examination of the heart and circulatory system. Habits of life, vocation of the individual, illness experienced, such as rheumatism, tonsillitis, grippe, mouth conditions which may produce foci of infection, should all influence the decision of the home office with reference to the insurability of the individual affected with a cardiac condition.

A bruit is merely an abnormal sound and its real significance depends on its location and rhythm, together with the associated or secondary signs. This is emphatically true of systolic murmurs, while a diastolic one is rarely if ever produced by any other condition than an organic lesion. A presystolic murmur possesses grave significance, and the prognosis depends largely on the secondary effects on the heart, as shown by the degree of enlargement of left auricle and right ventricle. Aortic regurgitation is a serious lesion for several reasons. When of rheumatic origin and well compensated it is not incompatible with the individual living to middle age, but such is the exception. Consequently, as with mitral stenosis, this valvular defect may be considered justly to bar the person against insurance unless as a defective risk at a high and practically prohibitive rate. With reference to a bruit in the aortic area, such as most practitioners regard as stenosis of the aortic orifice, it must be remembered that in aortic stenosis there is usually a systolic thrill having the same situation and time as the bruit, that the aortic second sound is either enfeebled or replaced by a diastolic murmur, that the left ventricle is distinctly hyperthrophied, and that blood pressure is low. On the other hand, if the aortic systolic bruit is found in a person of middle age, if the second sound is accentuated and perhaps clanging, if the accessible arteries are thickened, and if the blood pressure is abnormally high, the condition is probably sclerosis of the aorta and not stenosis. The left ventricle may or may not be hyperthrophied, and careful percussion as well as the *x*-ray may reveal some degree of dilatation of the aortic arch. In this case the coronary arteries would be diseased. Such a combination of physical findings justifies the rejection of the applicant. Occasionally there is found a soft, systolic murmur in the aortic area, particularly distinct when the person is in the recumbent position, which is not associated with a palpable thrill or appreciable alteration of the second sound. Neither is hypertrophy of the left heart or sclerosos of the peripheral vessels demonstrable. These cases are puzzling, but must be considered from the standpoint of anamnesis and age before being rejected. If the report is favorable from these points, then the bruit may be considered accidental and not organic. Another puzzling systolic murmur is that not infrequently heard in the second and perhaps third intercostal space at the left of the sternum. Such a murmur is common in women, especially when their hemoglobin is low. Sometimes there may be perceived also a soft, less distinct bruit at the apex and in the aortic area. Babcock considers that under these circumstances this murmur in the pulmonary area does not indubitably indicate mitral insufficiency. A systolic murmur at the base of the sternum may be produced by several conditions, namely, patency of the ductus arteriosus, patency of the foramen ovale, stenosis of the pulmonary orifice, mitral regurgitation, etc. These all need careful percussion and outside assistance in the form of the *x*-ray, etc., before a prognosis could be given. Pulmonary stenosis can scarcely be overlooked when it has led to the production of a systolic murmur in the second left interspace close to the sternum. The presence of a thrill, of a feeble and rudimentary second sound, and of hypertrophy of the right ventricle should not escape an examiner. This lesion is of course not insurable.

In the consideration of a systolic murmur in the mitral area two questions at once arise: Does a murmur always indicate mitral regurgitation, and if so, what is its influence on life prospect? If the first tone is also audible, if the apex-beat is in its normal situation, if the pulmonic second sound is not accented, if right heart dullness is not increased and undue epigastric pulsation is wanting, then an apex systolic bruit may be considered accidental or at least of no serious significance sufficient to warrant a refusal by a company. On the other hand, a systolic murmur at the apex in a person of middle age is of pathological significance in all probability and usually will be associated with significant changes in blood pressure, in the vessel coats and in the size of the heart, as well as in some of its tones. If this murmur is soft, may be heard more distinctly or only in the dorsal decubitus, and accompanies but does not replace the first tone, it is indicative of muscular mitral insufficiency. It goes without saying that prognosis in such a case is not favorable. Another systolic murmur sometimes heard and which may be mistaken for that of mitral regurgitation, is that of right ventricle dilatation from strain. This usually occurs in young men given to violent exercise and yields to digitalis and quiet living. The remaining systolic murmur to be considered from the standpoint of insurance is that of mitral regurgitation from rheumatic origin. There can be no doubt but that this lesion is the most favorable as regards prognosis of valvular diseases in general. Many an individual carrying a murmur due to mitral valve condition from rheumatism has lived to reach the allotted three score years and ten. This proves that more is to be reported in an examination of the individual than the recognition of a murmur, in fact all corresponding data should be noted. The prognosis of combined valvular lesions depends largely on the type of combination, but is most often doubtful.

Regarding prognosis in myocardial affections but little needs to be said, since no one would consider the acceptance of an applicant with unmistakable evidence of cardiac incompetence due to possible degeneration. Life prospects are too uncertain in cases of myocardial degeneration giving rise to symptoms of inadequacy. Simple intermittence of the pulse means little in young people, unless due to syphilis. In persons of middle age it takes on a significance according to the accompanying heart conditions. Babcock believes that persons with arrhythmic and degenerated hearts lack the subjective consciousness of the disordered action which so disturbs the individual in whom intermittence is a manifestation of a neurosis.—Medical Section, American Life Convention.

Book Reviews.

Diseases of the Nose, Throat, and Ear, Medical and Surgical. By William Lincoln Ballenger, M.D., Professor of Otology, Rhinology, and Laryngology, College of Physicians and Surgeons Department of Medicine, University of Illinois, Chicago; Fellow of the American Laryngological Association; Fellow of the American Laryngological, Rhinological, and Otological Association; Fellow of the American Academy of Ophthalmology and Otolaryngology, etc. Fourth Edition, Revised and Enlarged. Illustrated with 536 Engravings and 33 plates. Price, $5.50. Philadelphia and New York: Lea & Febiger, 1914.

An enumeration of the new topics and revisions that appear in the fourth edition of this work shows how well it has kept abreast of the progress that has been made in its subject-matter during the past few years. The most notable addition appears in the one hundred pages of new material on the labyrinth. There are thirteen colored plates illustrating the physiological and pathological manifestations of nystagmus, and twelve drawings portraying the Newman and Hinsberg labyrinth operations. The following are other new features of this work: Mosher's fronto-ethnoid operation, with five drawings; the use of autogenous vaccines in the treatment of hay fever; Haynes' operation on the cisterna magna; the His leucocyte-extract treatment of infections of the nasal sinuses and meninges; salvarsan in the treatment of syphilis of the brain and auditory nerve; and McBeam's theory of the causation of paracusis Willisii. Among the topics that have been revised may be mentioned the functional tests of hearing, otosclerosis, meningitis, and abscess of the brain. These additions and revisions, the large number of superb illustrations, and the excellence of paper and typography, not to mention the didactic and literary skill with which the subject-matter is presented, all tend to maintain the high standard which this work has already achieved.

A Short Handbook of Cosmetics. By Dr. Max Joseph, Berlin. Second English edition, revised with appendix. Price, $1.00. New York: E. B. Treat & Co., 1914.

Just as the alchemists were the precursors of the chemists, and the astrologers were the forerunners of the astronomers, so one may speak of the "beauty doctors" as the prototypes of the cosmetic specialists. Indeed the art of cosmetics has passed beyond the purlieus of the quack into the domain of the legitimate physician. In this small volume of 93 pages there is set forth a clear and practical account of modern cosmetics for the general practitioner. The chapter headings are as follows: Introduction, Cosmetics of the Skin, Cosmetics of the Hair, and Cosmetics of the Mouth. It may seem unnecessary to mention that this book is replete with formulæ and prescriptions of face lotions and creams, hair tonics, and the like. There can be no question that it supplies a distinct want in the physician's library.

A Manual of Practical Hygiene for Students, Physicians, and Health Officers. By Charles Harrington, M.D., Late Professor of Hygiene in the Medical School of Harvard University. Fifth edition, revised and enlarged. By Mark Wyman Richardson, M.D., Secretary to the State Board of Health of Massachusetts. In Collaboration with the Following Officials Connected with the Massachusetts State Board of Health: H. W. Clark, Chief Chemist; X. H. Goodnough, Chief Engineer; William C. Hanson, M.D., Assistant to the Secretary; Hermann C. Lythgoe, Chief Analyst of Food and Drug Department; and George H. Martin, formerly Secretary to the Massachusetts State Board of Education. Illustrated with Twenty-four Plates in Colors and Monochrome, and One Hundred and Twenty-five Engravings. Philadelphia and New York: Lea & Febiger, 1914.

This work represents a complete revision of the admirable treatise written by the late Dr. Harrington and considerably amplified by the editor in collaboration with officials connected with the Massachusetts State Board of Health, who have written special articles on foods, water supply and disposal of sewage, disposal of garbage, and hygiene of occupation. These topics are eminently live ones in latterday discussions on sanitary problems. In the section on milk as a factor in the spread of disease reference is made to the epidemic of 205 cases of sore throat occurring in Dover in 1884 and all traced to a single dairy supplied by cows suffering from foot and mouth disease. The chapter on the hygiene of occupations is a particularly forceful exposition of the facts pertaining to hazardous and dangerous occupations, and is illustrated with photographs showing card stripping in a cotton mill, the grinding of iron castings on emery and carborundum wheels, stone cutting, the broom-corn industry, shovelling lead oxide into hopper, lead working in the manufacture of storage batteries, the manufacture of derby and felt hats, the leather industry, pearl button making, etc. Reference is made to the admirable legislation enacted in the State of Massachusetts with reference to the protection of workmen and chiefly of minors. Of considerable importance and interest are the chapters on the medical inspection of schools; military hygiene; naval and marine hygiene; tropical hygiene; infection, susceptibility, and immunity; the relation of insects to human diseases; quarantine; the administrative control of communicable diseases; and vital statistics.

A Text-Book of Practical Therapeutics, with special Reference to the Application of Remedial Measures to Disease and their Employment upon a Rational Basis. By Hobart Amory Hare, M.D., B.Sc., Professor of Therapeutics, Materia Medica, and Diagnosis in the Jefferson Medical College of Philadelphia; Physician to the Jefferson Medical College Hospital; One-Time Clinical Professor of Diseases of Children in the University of Pennsylvania. Fifteenth Edition, Enlarged, Thoroughly Revised, and Largely Rewritten. Illustrated with 144 engravings and 7 plates. Price, $4.00. Philadelphia and New York: Lea & Febiger, 1914.

The new editions of Hare's "Practical Therapeutics" appear with periodic regularity, and the reviewer, beyond commenting upon the maintenance of the popularity and practical character of this work, has only to mention the new matter that has appeared in the latest edition, which in this instance is the fifteenth. The topics that have been added to or rewritten are those on salvarsan and neosalvarsan, tuberculin, anesthetics, and digitalis and other cardiac drugs. The attitude of the author in preparing the text is perhaps best stated in his own words as given in the preface: "The day has passed for undue therapeutic optimism and has gone far beyond therapeutic pessimism. This is the era of therapeutic rationalism, when remedies are given not because they are recommnded by, or said to be valuable by, some authority, but because their use appeals to the medical man who has a knowledge of the physiological, pathological, and therapeutic problems to be faced, and can, therefore, judge for himself what remedy is best suited to a given case when he is informed how it acts." The plan of the work is as follows: Part I deals with General Therapeutic Considerations; Part II, with Drugs; Part III, with Remedial Measures other than Drugs and Feeding the Sick; and Part IV, with Treatment of Diseases, Table of Doses of Medicines, Index of Drugs and Remedial Measures, and Index of Diseases and Remedies.

Chemistry for Nurses. By Reuben Ottenberg, A.M., M.D., Lecturer to the Nurses' Training School, Mt. Sinai Hospital; Instructor in Bacteriology, College of Physicians and Surgeons, Columbia University; and Assistant in Clinical Microscopy, Mt. Sinai Hospital. Price, $1.00. New York: The Macmillan Company, 1914.

The author of this book remarks in the preface "it puzzles one to understand how, in the past, without chemical instruction, nurses have made any sense at all of much that was taught them in materia medica, physiology, and diet cooking." Probably the nurses did not "make any sense at all of much that was taught them"; and it is believed that the present work will simply add to the mass of undigested matter which they do not understand. Why this book is entitled "Chemistry" we do not know; there is hardly a definition, or statement or explanation of chemical principles to be found in the volume. A glance at the index might cause a careless reader to infer that the volume is a somewhat complete book on chemistry; but on referring to the pages indicated it will be found that the presence of a word in the index frequently denotes no more than the mere occurrence of that word on a given page. The book contains a certain amount of information, but it lacks those features which characterize a good elementary work on chemistry.

Society Reports.

NEW YORK ACADEMY OF MEDICINE.

SECTION ON MEDICINE.

Stated Meeting, Held October 20, 1914.

Dr. JOSEPH C. ROPER IN THE CHAIR.

The Focus of Infection—Osteitis—and the Relation of Dentistry to Good Health; the Value of the Roentgen Examination.—Dr. BYRON C. DARLING presented this communication, in which he called attention to the numerous recent articles written by internists, neurologists, bacteriologists, orthopedists, and laryngologists, namely, Rosenow, Billings, Hastings, Camac, Joseph Collins and others, all concentrating the attention on the discovery and removal of the focus of infection as the first step toward the treatment of the particular condition. The clinical manifestations of these conditions in the order of their importance were: chronic joint affections, single or multiple; usually progressive with periods of improvement, directly related to the increase or decrease of the resistance of the patient. There was a great need of definite diagnosis in these cases; ulcers of the stomach and intestines; endocarditis; myocarditis; myositis; migraine; neuralgias; neuritis, and neurasthenia. To the finding of the underlying defect each department of medicine was making its contribution, emphasizing naturally that which lay within its own province. A routine order of search might well begin at the head, where they had first the respiratory tract; nose, throat, and tonsils; second, the middle ear and mastoid; third, the accessory sinuses; fourth, glands of the neck; fifth, the lungs and mediastinal glands. The author stated that this paper was written from the angle of view obtained from the use of the *x*-ray, and such an examination was recommended by the otologist as of the greatest value in mastoid conditions and of considerable value in sinusitis. In lung examinations it was the sole means of demonstrating the glands at the root of the lung, as well as supplementing greatly the physical examination of the lungs themselves. Second, in the routine order of search, was the alimentary canal. Here should be considered the possibilities of the roots of the teeth, the gums, and the jaws as harboring some focus of infection. Any decay extending to or causing the death of the pulp or nerve was a source of infection, which, if untreated, must result in a root abscess, osteitis, with or without fistulas. After describing Riggs' disease, the author said that the *x*-ray examination showed the absorption of the alveolar process about the root varying from an open space the width of a line between the tooth and its socket to that shown by a tooth loose in a bed and swollen and inflaming the gum with disappearance of the adjacent bone. More important still was the demonstration of the root abscess cavities, earlier and small ones as well as the larger ones with fistulas, and finally, whether the tooth had been properly treated by the dentist by completely filling it to its apex. Dr. Darling also reviewed the possibilities of the *x*-ray in locating ulcers of the stomach and duodenum and kinks and adhesions of the large intestine, biliary calculi, etc. Then followed as foci of infection the chronic infections, pyelitis, cystitis, urethritis, prostatitis, and seminal-vesiculitis. Most of the conditions mentioned lay within the province of and were definitely cared for by some one of the distinct specialties of medicine, but the teeth fell between the province of the dentist and the physician, who seldom met for cooperation in diagnosis. Wherever any suspicious condition of the mouth brought the teeth into question the matter should be gone into thoroughly by both the physician and the dentist, leaving no "hidden focus" undiscovered. The physician should examine the mouth of such patients both before and after the dentist had done his work, for too often after the dentist had completed his work the *x*-ray still showed definite lesions.

Dr. Darling gave an *x*-ray exhibition of certain conditions of the teeth already referred to seemingly related to conditions such as multiple arthritis, hip joint disease, destructive lesion of the spine, septic endocarditis, spondylitis deformans, etc. He concluded as follows: (1) As a first, rather than a last, resort, special attention must be paid to the condition of the teeth. (2) Good health demands the constant close attention of a conscientious and scientific dentist. (3) Much old and unscientific dentistry, such as bad crown and bridge work, and unscientific root filling, must be removed and the conditions remaining properly treated; failing this, merciless extraction, with false teeth, but a clean mouth. (4) Pyorrhea alveolaris was a menace to good health, and certainly could be a focus of infection. (5) There should be cooperation with mutual recognition of responsibility between the physician and the dentist. (6) Even though the hidden focus was found and the cause of the systemic infection removed, the seed of the disease had already been sown broadcast and many expedients would be required before the patient was cured.

Dr. R. OTTOLENGUI said that he quite agreed with Dr. Darling as to the value of the *x*-ray in aiding in the diagnosis of septic conditions of obscure origin. Whilst he did not consider that it had yet been absolutely proved beyond scientific doubt that microorganisms, more especially streptococcus viridans, might migrate from root ends to distant parts of the body, causing serious functional disturbances, he was inclined to believe that the time was far off when such proof would be had. In fact, the researches of Dr. Thomas B. Hartzell went very far to substantiate this view. (For a full report of Hartzell's researches to date, beautifully illustrated in color, see official bulletin of the National Dental Association, Volume 1, No. 4, page 48.) Passing this phase of the subject, Dr. Ottolengui said that he would address himself more particularly to the dental aspect. He pointed out that there were no less than three sources of infection in the mouth. First, from pus discharging around teeth, associated with pyorrhea alveolaris; second, from pus discharging through fistulæ leading from the ordinary type of alveolar abscesses; and third, from moderately small granulomas, which were to be found at the ends of root canals, but which did not have fistulous openings, and which, therefore, did not discharge pus into the mouth proper. Dr. Ottolengui said that as the pus discharged from the first two conditions were easily discoverable by the physician, he would discuss more particularly those of the third class, commonly known as blind abscesses. The dangerous feature of these infections lay in the fact that they gave no pain, caused the patient no disturbance whatever, and were most commonly found on teeth which might appear to be well filled and perfectly sound. No tooth, however, was really well filled, supposing that the pulp had been removed prior to filling, unless the root canals were aseptically filled absolutely to their ends, and it was even preferable that a little of the filling material should extrude beyond the end, thus insuring absolute sealing of the frenum. Where a root filling did not reach the end, infectious material was laying in the unfilled portion of the canal and almost invariably resulted in infection. This infection was frequently from a low type of bacteria, very slow in growth, and as they now knew, exceedingly dangerous to the rest of the body. It was, therefore, important for the medical man when, seeking for the cause of the infection, especially where he suspected the mouth, to have radiographs made of all teeth known to be pulpless or suspected to be pulpless because of the presence of very large fillings. In this manner and in this way only could it be determined whether or not granulomas were present. The radiograph easily disclosed this, however, because the root fillings as commonly used were of gutta percha and readily stopped the ray, casting a clean-cut shadow. The root of the tooth did the same, and consequently it was easy to determine whether or not the root filling really reached the end. If it did not, the tooth must either be unfilled and correctly refilled, the same to be proven by the radiograph or else it would be best to sacrifice the tooth by extraction. Dr. Ottolengui then exhibited, with the aid of lantern slides, the accepted method of filling root canals as practised by the most advanced dentists. This involved the clearing out of the root canal as far as the dentist might find it possible at the first sitting. A gold wire was then inserted into the root canal and a radiograph taken. The shadow cast by the wire then disclosed whether or not the dentist had really cleaned out the root canal to the end and the cleansing was continued until a radiograph was obtained which did show a wire passing to or even through the end of the root. The next step was to fill the canal and take another radiograph, by which the dentist checked up his operation and determined whether he had successfully filled the tooth to the end. Dr. Ottolengui declared that a medical man would be warranted in even recommend-

ing a change of dentists where the patient presented teeth with several badly filled roots. In fact, he believed that this course followed by the medical men might be a valuable lever to compel the dental profession to be more cautious and more thorough in this work. The medical men, however, could be of considerable assistance to the dentists in explaining to the patient the importance of having this work well done, because it was an undoubted fact that patients did not appreciate the value of this root service and were unwilling to pay for it. A great majority of the dentists had rather shirked the rather tedious technique necessary to the accomplishment of perfect results.

The Management of Pneumonia Patients.—Dr. SIMON BARUCH read this paper. (See page 993.)

Dr. BARUCH said in reply to questions by Dr. Harlow Brooks and others that he ordered the ten-minute friction bath at 95° F., reduced rapidly to 85° or 80° F., in the pneumonias of children under five years of age, repeating every four to six hours if chilliness was absent an hour after the bath, when the chest compresses were again applied. In reply to the question if he did not regard the cold bath as valuable in sunstroke, Dr. Baruch said that *it was absolutely coontraindicated in this disease* and that its continued recommendation in most books on practice was responsible for many deaths, as had been demonstrated in his work on hydrotherapy. In an article on the fatality of textbook hydrotherapy in the MEDICAL RECORD of 1912, the dangerous fallacy of regarding the coldest bath as the most antithermic was emphasized in order to put a quietus on it. The most popular textbook, translated into many languages, had long stated that the ice-pack gave the best result in this fatal disease, viz., 38 per cent. This was disproved by the fact that an epidemic of sunstroke in New York City killed, in 1896 in one week, 648 persons, the mortality being under iced baths and ice-packs in Bellevue Hospital, 33 per cent.; in the Flower Hospital, under the needle spray of tap water (75°), given only until rectal temperature fell to 103° F., the mortality was 11.5 per cent.; under pouring cold, sometimes iced, water with force over the body and with friction until 103° F. was reached, the mortality was only 6 per cent. in the St. Vincent Hospital, under the lamented O'Dwyer. And Osler's great textbook still taught in its sixth edition the value of the ice-pack, with its 38 per cent. mortality! The lesson he wanted to impress upon them was that the chief action of cold water was upon the vasomotor centre and sympathetic systems, which regulated the functions, including the heat regulation; also that reaction must ensue after all cold procedures by which he did not mean reddening of the skin, but *bien aise* or at least absence of discomfort. He begged of them to stop ordering water treatment unless they had mastered the simple principles upon which safety and success depended. Often they heard and read that hydrotherapy was ordered. This was quite as absurd as to state that drug therapy was ordered. That there might be even a fatal difference between the effect of a cold tub bath and an affusion or spray with water of the same temperature (both being hydrotherapy) the sunstroke observations he had mentioned proved more clearly than any therapeutic fact had ever demonstrated. Let them prescribe water as they prescribed drugs; then would they obtain apparently incredible results.

MEDICAL ASSOCIATION OF THE GREATER CITY OF NEW YORK.

Stated Meeting, Held October 19, 1914.

THE PRESIDENT, DR. THOMAS S. SOUTHWORTH, IN THE CHAIR.

A Case of Dystrophia Adiposogenitalis.—Dr. EDWARD WAITSFELDER reported this case, presenting the patient. We were somewhat familiar he said, with the action of the internal secretion of the thyroid, suprarenals, testes, and ovaries, as well as, to a lesser extent, that of the thymus; but in connection with the hypophysis, with its different lobes, each having a distinct secretion acting in a different way, there were many problems still to be worked out. Whether, for example, the internal secretions of the testicle and pituitary were synergistic or antagonistic in their action; and whether the persistent thymus gland reacted on the pituitary, and gave rise to symptoms due to faulty function of the latter, and not the thymus, as had heretofore been supposed, as in the case of status lymphaticus, rickets, etc. The patient presented was a Swede, 27 years old. As a child he was stouter than his companions, and when he grew older his schoolmates called him a woman. He preferred to be alone, did not like outdoor sports, and was rather feminine in his tastes. From the age of 15 he had been a ship's cook. He did not use tobacco or alcohol, and denied coitus, masturbation, and libido. One year ago he received a severe blow on the head, since which time he had suffered from headache; and it was for this symptom that he was admitted to Dr. Waitsfelder's service at the Gouverneur Hospital. The patient had the beardless "moon" face so frequently seen in castrates; shoulders sloping, feminine outline; increased deposits of subcutaneous fat under the chin, in the mammary region, nates, and more particularly over the abdomen and mons, where it formed a large cushion. The penis, scrotum, and testicles were extremely small and rudimentary, and there was an absence of pubic and axillary hair. The thyroid gland could not be felt, the larynx was small and cartilaginous, and the voice was high-pitched and feminine. He could read and write, and was much more intelligent than the ordinary seaman. During the first three weeks of his stay in the hospital he was quiet and reserved, but was willing to help about the ward. He was neat in his habits and in no way troublesome. An *x*-ray examination of the skull showed a remarkably small sella turcica, the transverse diameter being 10 mm., and the longitudinal 6 mm. A bridge or arch of bone (undoubtedly congenital) rendered it possible to get the latter measurement. An *x*-ray examination of the bony pelvis showed a decided departure from the usual conformation of the male pelvis, the pubic arch being much wider, the ilia more flaring, and the outlet of the pelvis larger. The femur also somewhat resembled that of a female. The extreme smallness of the pituitary fossa indicated an absent or inefficient pituitary gland, and Dr. Waitsfelder therefore determined to transplant one as soon as the opportunity offered. On August 15, ten hours after death, the pituitary and pineal glands of a robust German, aged 25, who had committed suicide, were removed under strict aseptic precautions and transplanted in the patient—the former in the axillary border of the right pectoral muscle; the latter in the left pectoral muscle. The operation, which was done under nitrous oxide anesthesia, was followed by primary union. On the day following the transplantation a remarkable change took place in the patient, and this continued until his discharge, two weeks later. He became noisy, abusive, and unruly, tearing off the bandages over his wounds, insisting on removing his clothes and going about the ward naked, and continually swearing at nurses and patients. He became filthy in his habits, frequently wetting the bed, and when remonstrated with he was very obscene, and threatened to strike the nurse. Finally he became so unmanageable that he had to be transferred to the City Hospital (on August 31). For the first week after his removal he acted in the same violent way; at times requiring restraint. He then gradually grew more reasonable and quiet, and on October 10 re-entered Gouverneur Hospital. Since then his condition had appeared to be precisely the same as before the transplantation. A fairly extensive search through the literature on the pituitary, the speaker said, had failed to reveal a parallel case, either as regards the lack of the gland or the attempt to establish this internal secretion by the transplantation of a pituitary taken from a human subject. The mental state of the patient following the transplantation had given him considerable thought, and it seemed a fair inference that this had been due to the activity of the internal secretion of the pituitary, inasmuch as it had developed on the day following the introduction of the gland, and subsided after a length of time which might be sufficient to allow the gland to be absorbed. It was unfortunate that the attempts, four in number, which had been made to get an *x*-ray picture of the thymus gland had failed, probably because of the excessive fat deposits over the thorax. The patient's appearance was suggestive of status lymphaticus, a condition in which an enlarged thymus was frequently found.

Dr. REYNOLD WEBB WILCOX referred to a case of retarded growth which he had reported to the American Therapeutic Society in 1908. When the patient came under his observation he was 14 years old and had not grown any for the preceding three years. From the fact that the thymus remains large during the period of growth, and then atrophies, it was reasonable

to suppose that this gland has to do in some way with the general growth of the body. It therefore seemed possible that this boy's lack of growth might be due to thymus deficiency, and, acting on this hypothesis, Dr. Wilcox advised a course of thymus extract. The result was such as might well be considered startling, for in the next three years, during which the extract was administered, with some intermissions, there was a gain of 9½ inches in height and 43 pounds in weight. This single instance, however, the speaker said, did not prove anything. The whole subject was still very obscure, and it might be that the remarkable result observed in this patient was simply a coincidence.

Dr. ROBERT T. MORRIS said that most of the ductless glands belonged to closely connected growths, but the ovary did not appear to be in quite such intimate relationship with any other gland. In his case of testicular grafting, in 48 hours from the time when the grafting was done, the patient was conscious of masculine cenesthesia, after ten years of loss of such feeling. It was extremely difficult to secure a successful transplantation of any of the ductless glands, but in very rare instances normal function could be restored, so far as internal secretion influence was concerned, and sometimes, in the case of an ovary, children might be born.

Dr. WAITSFELDER said he thought there could be little doubt that there was a relationship between the thyroid and the ovary, for the first menstruation was commonly attended by congestion of the thyroid. In Dr. Morris's case of heteroplastic grafting of the testicle he believed it quite impossible that, under the circumstances, there could have been any emission of semen, as claimed by the patient. The secretion noted was, without doubt, that of the prostate. Eunuchs, it was well known, were capable of having erections, with the emission of prostatic secretion.

Pelvic Abscess Following the Employment of the Fowler Position in Appendicitis.—Dr. H. BEECKMAN Delatour, in this paper, said that while the elevated head and trunk posture, known as Fowler's position, had proved a most valuable aid in the saving of appendicitis cases with general peritonitis, it was his belief that a large proportion of the cases reported as instances of general suppurative peritonitis were really not true cases of general peritonitis. In numerous cases of acute appendicitis in which the abdomen was full of serum clouded with lymph, but in which there were not found those changes recognized as inflammatory, it had long been his practice, if the appendix, although gangrenous, had not perforated, to close the abdomen without irrigation and without drainage. Many such cases, he believed, had been reported as cases of purulent peritonitis, and the recovery of the patients credited to postural treatment. He did not wish, however, to convey the impression that he lacked faith in the elevated trunk position as an aid in septic cases. As to whether, in these, it was possible to drain away all the septic material by drainage carried into the pelvis, apparently in the majority of instances this drainage was all-sufficient; but in a few it was not, as some case histories he would present would show. Most surgeons had met with appendicitis cases which had been drained and had done well up to a certain point, but the temperature never became normal and the wound ceased to drain. In some instances, however, the temperature would, after a time, suddenly become normal, and the whole condition improve. From his recent experience he was inclined to believe that in all such cases there was in the deep pelvis a small collection of pus, not highly infective, which was never drained. In those in which the sudden improvement occurred the abscess ruptured spontaneously into the rectum, and the discharge of pus was not recognized. In some the process was not very active, and later encapsulation occurred, or the exudate was absorbed. In 1898, in a paper published in the *Brooklyn Medical Journal*, he had called attention to the importance of rectal examination as an aid to diagnosis in doubtful cases of appendicitis. In conjunction with the cases referred to he wished to again advocate this method as one of the recognized procedures which was frequently not employed. His attention was first directed to the development of pelvic abscess following appendicitis by a case in which the Fowler position was used at the Norwegian Hospital three years ago, which he described. On introducing the examining finger into the rectum there was considerable pain. The finger then detected, just beyond the prostate, a mass bulging into the rectum, and this had so much the feel of a distended bladder that further examination was deferred until the bladder had been emptied. This having been done, the mass was found to be still present, and it gave the sense of fluctuation. Concluding that he had a pelvic abscess to deal with, he had the patient put under ether, thoroughly dilated the sphincter, and introduced a speculum. The bulging in the anterior wall of the rectum was plainly visible, and after the mucous membrane had been thoroughly cleansed a longitudinal incision was made into the mass. About three ounces of pus was evacuated, and a half-inch drainage tube, covered with iodoform gauze, introduced. From this time the temperature became normal, and general improvement followed. On the fourth day all drainage ceased, and two weeks after the evacuation the patient was discharged entirely cured. Since this case the speaker had had six similar ones, which led him to believe that the condition is not rare. In one of them, in which the mass was small and at some distance from the anus, he had employed aspiration with satisfactory result. The point which he desired to emphasize was that in those cases of septic peritonitis in which there is continued increased temperature, but in which the wound looks healthy and careful examination of it shows no undrained pockets, one should be sure to make a rectal examination, especially if the patient be losing ground and has frequent bowel movements, with tenesmus and discharge of mucus. If, on examination, an abscess were found, we should not hesitate to drain it through the rectum, as there was apparently little or no danger of infection from this source. While aspiration might prove satisfactory, he would recommend incision whenever possible.

Dr. MORRIS said that we should always take into account the character of the fluid present in the abdominal cavity. Where this was of thick consistence there was one danger to be apprehended. In the Fowler position gravitation acted more strongly than in most, and there was a tendency for the fluid to pocket and make its way into some one of the hollow viscera. He had been glad to hear Dr. Delatour advocate draining an abscess through the rectum, and it appeared to him to be an excellent plan. With the prone position we were perhaps more likely to have consolidation pneumonia and subphrenic abscess, but, after all, he had not been convinced that any one position offered great advantages over another. The general experience of our hospitals seemed to show that, as a rule, the prone position of the patient was the most desirable. So many patients got well in any sort of position, however, that posture was apparently not a matter of vital importance.

Dr. RUSSELL S. FOWLER said that, postoperatively, pelvic abscesses occurred in two classes of cases: those in which the foundation for the abscess already existed at the time of operation, and those in which material descended to the pelvis, after the operation, from some other part of the abdominal cavity. A separate pelvic abscess might also exist undiscovered at the time of operating upon the original focus. By bearing in mind these three conditions at the time of operation, subsequent abscesses could for the most part be avoided. As to an abscess already existing, it was possible to remove an appendix with so little disturbance of the surrounding intestine as not to rupture or discover an abscess in the neighborhood. Several times he had so removed an appendix, only to discover, by passing a stick sponge into the pelvis, that there was present a distinct collection of pus there. Such cases occurred without reference to the posture of the patient. In females the abscess was drained by a posterior colpotomy, the abdominal wound being closed; while in males a curved glass drainage-tube, with its lower end in the pelvis, was employed. The other two classes of pelvic abscess might occur in spreading peritonitis and in diffuse septic peritonitis cases. In the former it was a question of judgment whether pelvic drainage by vagina or glass pelvic tube should be used at the time of the original operation, or whether no drainage should be employed. At operation there was present a slight amount of sticky fluid in the pelvis. Personally, he usually drained these cases for from 24 to 48 hours by means of a glass tube, though sometimes the pelvis was simply sponged dry, and no drainage used. In such cases not drained it was easy to understand that posture might result in a further collection and localization of the infected material in the pelvis. He himself had not noted post-operative pelvic abscess in this class. When diffuse peritonitis existed, unless the pel-

vis were drained, there was always a possibility that a pelvic abscess would form. Formerly he had closed tight an occasional case of diffuse peritonitis where the peritoneum did not show much structural change, and he did not note secondary abscesses in these cases. His usual procedure, however, was to drain such cases with a glass tube; in which event secondary pelvic abscess did not occur unless the tube was withdrawn or shortened too early. Still, occasionally he had observed an abscess form at the pelvic brim, on the left side. Such an abscess could be opened by removing the tube and inserting the finger through the tube-tract into the pelvis and curving it upward and to the left, thus opening the abscess into the pelvis. In other instances it was necessary to open the abscess on the left side, through an abdominal incision. Secondary abscesses, of course, occurred in other locations in diffuse peritonitis cases. Except in these three ways he did not see how a pelvic abscess could occur post-operatively, nor did he think that the non-use of the Fowler position would prevent the formation of such. These abscesses were bound to occur, so that the position of the patient was instrumental only in localizing them. The examination by rectum, he thought, was important.

Dr. Franz Torek said that after the proper treatment of the abdominal cavity in diffuse suppurative peritonitis (a condition involving the entire peritoneum right and left), in which all the pus had been removed, there was none left to make its way down into the pelvis when the Fowler position was employed. The condition of affairs could be compared to that when a small quantity of liquid was sprinkled on a pane of glass placed upright. It would not follow the law of gravitation, but would adhere to the side of the glass. For this reason he did not put his patients in the Fowler position, except occasionally for the sake of comfort. Fowler had done a great service by reducing the amount of drainage resorted to. Personally, he thought it better to employ no drainage at all. In his cases of diffuse suppurative peritonitis, which included a number of four days' duration, the mortality had amounted to 16 2-3 per cent. In his first series he did not drain a single case. In his operations for this condition, after thorough cleansing of the abdominal cavity the wound was closed completely. In his second series of cases he had in two instances drained down to the cecum, because in that portion of the intestine there was an appearance of threatening gangrene. Here the drain was introduced simply as a safety valve, and not as a means of draining the peritoneum; for it was impossible to drain that. He did not believe that the use of Fowler's position would cause pelvic abscess, and this opinion was based upon the view, previously expressed, that minute quantities of liquid would be controlled by the attraction of adhesion, not that of gravitation.

Dr. Delatour, in closing, said the title of his paper might give the impression that he thought the abscesses were entirely due to the Fowler position. Such was not the case, though he did believe that it was a contributory factor. It had been his practice to employ drainage when there was a leakage from a perforation, but not when there were no perforation and leakage. None of his cases had been in females, but in a case in a woman he would evacuate through the vagina, rather than the rectum.

Physical Defects as a Factor in the Causation of Crime.—Dr. Edward Wallace Lee read this paper. We were told, he said, that man was created in the image and likeness of God, and he interpreted this to mean that the design of Nature was toward perfection, and that perfection would be attained, and superman evolved, were it not for accidental interference. From this standpoint he would maintain that mankind would be morally perfect if it were physically perfect. Men had come to realize that soul, spirituality, and moral sense are the product of intelligence and education, that intelligence is the product of a physiological metabolism, and that the extent of an individual's education depends upon his intelligence, taking into account, of course, the factor of environment. Mankind would have made its greatest progress when it could say, "I am too intelligent to commit a crime." Under our present educational standard every normal, intelligent individual knew what he could do or not do, so far as breaking the criminal laws was concerned. He believed, therefore, that every person who did break these laws was deficient in intellectual control, and that the loss of this control was due in part to some physical defect which destroyed moral stamina. The factors entering into the causation of physical defects were many and might be classified under three headings: congenital, acquired, and accidental. Alcohol was the principal factor concerned with all three classes, and he regarded this as the most potent factor in physical and mental degeneration. The recent researches of Bezzola seemed to prove that the old belief in the bad quality of children conceived during drunkenness was not without foundation. According to the statistics of Forel, about 75 per cent. of venereal disease was contracted by persons under the influence of alcohol. The production of the majority of sexual crimes, also resulting from want of reflection and general motor impulsiveness, could likewise be attributed to its use. Drink made men and women not only gross and sensual, but also negligent, imprudent, and irreflective. The saloon took men from their homes, while addiction to alcohol directly diminished population. Other things being equal, it was found that the nations which abstained from alcohol, or those in which the people were moderate consumers, were more prolific than those given to drink. Alcohol greatly deteriorated the quality of man by causing blastophthoria, or deterioration of the germ, and we must agree with Darwin, Gladstone, Cobden, and Comte that alcohol, even in moderation, does more harm to a nation than war, plague, and famine combined. The recent order regarding alcohol issued by our Secretary of the Navy should place him among the greatest benefactors of the human race. Alcohol, internally, was nothing but a narcotic, and the day would come when medical men who were addicted to intoxicating liquors, or who prescribed them, would be considered a menace to the best interests of society. Personally, he had witnessed eight legal hangings and three or four which were not legal, and the primary cause in all was alcoholic intoxication. The abuse of the use of drugs entered largely into the causation of crime, and there was no strong argument against the crusade now being made to wipe out the pernicious drug habit; but it did seem somewhat inconsistent to make such an energetic war on habit-forming drugs while alcohol was being dispensed ad libitum. From his present viewpoint he would maintain that any pathological condition may be the exciting cause of a psychic neurosis leading to such a disturbed physical change as will result in mental deterioration and acts of crime. Not that all physical defectives were criminals, but he did believe that in all criminals a physical defect might be the exciting cause of criminal instincts. The various physical defects that could be mentioned as the underlying causes of mental deterioration were unlimited. It was only necessary, however, to mention a few in order to demonstrate his ideas along these lines. The speaker then took up successively the deleterious effects of syphilis, malaria, and food. In speaking of the last-named he referred to improper food, proper food improperly prepared, and food immoderately ingested, and in this connection he spoke of some of the mental and psychic results of the toxemia due to intestinal disturbances. He went on to say that crimes were punished too much because they were infractions of the law, the mental and physical condition of the individual not receiving sufficient consideration. Every observant physician knew of mental relief resulting from physical relief, and it would be well for medical men, in making up patients' histories, to find out as much as possible regarding their temperament and moral status. When criminals of all classes were treated as pathological subjects we would be in a position to arrive, by thorough analysis, at their true psychological state, and the more we investigated with the view of ascertaining to what extent all criminal acts were the result of pathological conditions, the better would we be able to handle this most important subject. He believed that sexual perversion and sexual crimes were largely due to some physical defect, especially in the genital tract. He had long advocated castration as a treatment for a certain class of these cases, and had resorted to it a number of times with good results. We all knew the mental effects of pathological thyroids, and the benefit resulting from proper treatment. Now, as to what should be done. In general, the abolition of everything which had a tendency to deteriorate physically the human race. Scientific, not sentimental, eugenics, together with an appreciation of the fact that crime is a disease, should be the starting point. He advocated the careful examination of children and of criminals, and said that the inmates of our penal institutions could be divided into three classes: those who should never have been confined, those who should be treated with the hope of cure, and

those who should be eradicated. The first was composed of individuals who were punished largely through technicalities and did not belong in such institutions. In the second were those who, under proper physical treatment, education, and environment, might be benefited and trained to be useful citizens; and in the third were mental, moral, and physical defectives suffering from atavistic traits, to whom no manner of treatment or punishment would be of the slightest benefit.

Mr. A. C. VANDIVER, counsel to the Medical Society of the County of New York, said it had not been his experience that most crimes were due to physical defects in the criminal. In fact, he had never seen any which he had reason to believe were due to such defects, or even to alcohol.

Mr. DREYER said that the growing child was wholly subject to development, and spoke of the necessity (in order to prevent the creation of criminals) of proper training in accordance with the child's aptitudes.

Dr. MORRIS said that crime was a comparative matter, and in a young man at the age of romanticism it was often due to a spirit of adventure, and sometimes was the result of alcoholic impetus given to a concept. There could be no question as to the desirability of individual training of the child, and this was the ideal of all educators.

Dr. ARTHUR C. BRUSH said that criminals could be divided into two classes: those whom hunger or some other cause compelled to break the law, the accidental criminals; and those who did so because they could not understand the nature of the act or control their impulses. The latter were the habitual criminals, and Lombroso was right up to a certain point as to the frequent occurrence of certain physical deformities in this class. Physical defects were also contributory causes from the fact that they might make the subject an object of contempt or so handicap him that he was unable to keep up with his fellows, and had to resort to crime in order to live. He did not agree that all of this class were of low mental type. In many, as the negro and the Southern Italian, there was marked loss of self-control, just as was found among imbeciles; but there were also those who presented a high degree of mental acuity. The influence of alcohol he thought had been overestimated, for, judging from the habits of Englishmen a century ago, we should now have a degenerate race instead of the present vigorous one.

Dr. J. HERMAN BRAANTH said that by scientific investigation it had been shown that much of criminality, if not all, was due to nervous instability, feeblemindedness, and insanity, and one might without exaggeration say that every feebleminded person was a potential criminal. Heredity and alcoholism were important etiological factors. Dr. Alexander Lambert had stated that many defectives were such owing to alcoholism in the parents, and, as mentioned in a paper written in 1901, in five out of six cases of cleft palate which he himself had seen within a short time, the mothers admitted alcoholic intoxication of one or both parents at the time of conception. A low grade imbecile was more dangerous than a total idiot, but less dangerous than a high grade imbecile, a class which principally made up the criminal element in the community. Mental life was of far greater importance than pyhsical life, and the highest life was attained through cultivation of both mind and body. In the savage was seen the cultivated body and uncultivated though normal brain.

Dr. WILLIAM SHARPE described the first case in which he had done a right subtemporal decompression for the relief of spastic paralysis, in a child that was in a dying condition. This he said was eighteen months ago, and the patient had greatly improved and was now practically normal in his mentality. Since then he had had 79 cases, with 6 deaths. He was accustomed to operate only on the mild cases, and the results, both physical and mental, had been very gratifying.

Dr. M. S. GABRIEL said the views put forth by Dr. Lee were entirely too materialistic.

Creatine and Creatinine Elimination in Diabetes and Nephritis.—D. Lampert states that in diabetes the creatinine excretion either is diminished or approaches the lower limits of the normal variations. In diabetes gravis with a high degree of acetonuria creatine is present in the urine, but in diabetes levis with traces of acetone creatine is either absent or present in slight traces. In nephritis there is always a diminution in the creatinine even when there is a good diuresis.—*Zeitschrift für klinische Medizin.*

State Medical Licensing Boards.

STATE BOARD EXAMINATION QUESTIONS.

TENNESSEE STATE BOARD OF MEDICAL EXAMINERS.

May 4 and 5, 1914.

(*Concluded from page 950.*)

PRACTICE.

1. What conditions are accompanied by severe pain in the chest, and what characteristic symptoms would enable you to differentiate them?

2. In a case of uremia, indicate the various conditions that must be considered; state the appropriate remedies for each condition and give definite reasons for the use of each remedy.

3. Describe briefly the following diagnostic signs or tests and name opposite each, the disease or diseases in which they may be found: Koplik's spots; Romberg's symptoms; Argyll-Robertson pupil; Babinski's reflex; Kernig's sign; Stokes-Adams syndrome.

4. (*a*) Name the cardinal symptoms of tumor of the brain. (*b*) What is the diagnostic value of pulsating jugulars.

5. Differentiate cardiac hypertrophy and dilatation.

6. Give the cause, symptoms, and treatment of cerebrospinal meningitis; the symptoms of tuberculous meningitis.

7. Name the causes of displaced apex-beat and state the physical signs of one of the conditions mentioned.

8. (*a*) Diagnose and treat herpes zoster. (*b*) What causes a large per cent. of all cases of early blindness? Give preventive treatment.

OBSTETRICS.

1. Give (*a*) bones, (*b*) divisions, (*c*) straits, and (*d*) symphyses of the obstetric pelvis. In what way does it differ from the male pelvis?

2. Name the internal female organs of generation. Describe the uterus fully, and give its relations to the other organs in the pelvis.

3. What is menstruation? How soon would a woman menstruate after parturition?

4. Describe the pregnant uterus, and state how it differs from a normal uterus. How early can you diagnose pregnancy? Give the signs by which you would do it.

5. Give a differential diagnosis between a supposed six months' pregnancy and an ovarian tumor; a uterine fibroid; ascites; a gaseous accumulation.

6. Give the proper management of the breasts before and after labor.

7. Give all the means or drugs that you know to facilitate a tedious and painful labor.

8. What precautions would you take in obstetric work in case of a doctor or nurse who had been in attendance on a septic case?

SURGERY.

1. Give the symptoms, complications, and treatment of fracture of ribs.

2. Define toxemia, septicemia, pyemia, sapremia.

3. Give the causes, symptoms, and treatment of suppurative mastoiditis.

4. Give symptoms of simple, compound, and compound comminuted fracture of tibia and fibula and treatment of each condition.

5. What articular changes take place in dislocations? What are the general principles governing the treatment of dislocations?

6. Differentiate benign and malignant tumors. Name two of each.

7. Give symptoms, diagnosis, and treatment of tuberculous kidney.

8. Give the etiology, symptoms, and varieties of erysipelas.

ANSWERS.

PRACTICE.

1. *Pain in the chest may be due to:* Anemia, intercostal neuralgia, pleurodynia, pleurisy, pneumonia, phthisis, mediastinal tumor, enlarged bronchial glands, herpes zoster, disease of the vertebræ, angina pectoris, pseudo-angina, pericarditis, gastralgia, gastric neuroses, gastric ulcer, gastric cancer, ulcer of duodenum, aneurysm.

2. *Uremia* may occur in the course of acute nephritis,

chronic nephritis, puerperal eclampsia, and when there is obstruction to urinary excretion. *Remedies*—Hot pack, to increase elimination by the skin; elaterin, to increase elimination by the bowels; nitroglycerin, to lower arterial tension; strychnine and digitalis, to support the heart; chloral or chloroform for the convulsions; sometimes venesection and hypodermoclysis will cause general relief from all the symptoms.

3. *Koplik's* spots are small red spots with a bluish-white center, found on the inner surface of the cheeks; they occur in the beginning of measles, prior to the appearance of the rash.

Romberg's Symptom: The patient stands with eyes closed and heels together; extensive swaying of the body occurs if the patient has ataxia of the lower extremities; found in locomotor ataxia.

Argyll-Robertson pupil: The pupil responds to accommodation, but not to light; found in locomotor ataxia, intracranial syphilis, and progressive paralysis of the insane.

Babinski's reflex: When the sole of the foot is tickled there is extension of the toes instead of flexion; occurs in lesions of the pyramidal tract, organic hemiplegia.

Kernig's sign: The patient lies with the thighs flexed upon the abdomen and the legs flexed upon the thighs; if cerebrospinal meningitis is present it will be impossible to extend the legs.

Stokes-Adams syndrome is a complex consisting of slow pulse, cerebral disorders (as vertigo, syncope), and visible auricular pulsation in the veins of the neck. It occurs in heartblock.

4. *Tumor of the brain:* Chief symptoms are headache, vertigo, vomiting, optic atrophy, choked disc, slow pulse, convulsions, and the focal symptoms (which vary according to the location of the tumor).

Pulsating jugulars may denote: Anemia, tricuspid stenosis or regurgitation; the condition may be observed in health.

5. CARDIAC HYPERTROPHY: "*Inspection* reveals fullness or prominence of the precordium with a distinct impulse. *Palpation* detects the impulse one or two intercostal spaces lower down and to the left. It is stronger and more or less diffused—the heaving impulse. *Percussion* determines an increase in the area of cardiac dullness vertically and transversely on the left side of the sternum, unless the right ventricle is also hypertrophied, when the cardiac dullness is increased to the right of the sternum. *Auscultation* in simple hypertrophy without any valvular changes detects a loud first sound of a somewhat metallic quality, the second sound being strongly accentuated. In the presence of valvular disease the characteristic murmurs are heard in addition."—(Hughes' *Practice of Medicine.*)

CARDIAC DILATATION: "*Inspection* detects enlargement and distention of the superficial veins and an indistinct, often wavy and diffused, cardiac impulse. If tricuspid regurgitation is present jugular pulsation will be observed. *Palpation* confirms inspection; the impulse is feeble, irregular, and heaving. *Percussion* serves to determine extension of the area of cardiac dullness transversely and especially toward the right side. *Auscultation* in the presence of valvular lesions reveals characteristic murmurs. If there are no valvular lesions the cardiac sounds are weaker than normal and the first sound is sharper in quality than usual."—(Hughes' *Practice of Medicine.*)

6. CEREBROSPINAL MENINGITIS. *Cause:* The *diplococcus intracellularis meningitidis. Symptoms:* "The symptoms depend upon the area most affected. If the meninges of the brain are diseased, there are delirium, stupor, paralysis of ocular muscles, disturbed vision, deafness and semi-consciousness. If the meninges of the cord are the seat, there will be opisthotonos, hyperesthesia, paresthesia, rigidity and tremor of the extremities, localized spasms of the muscles, which, if irritated, often cause a general convulsion. The onset is characterized by anorexia, malaise, pain in the back of neck, head, and down the spine, slight rise of temperature, chill, or convulsion. Vomiting comes on early, and the pain in the back and head increases. The temperature is not usually high—about 102°—very irregular, and without the diurnal variation so common in typhoid fever. The pulse is full and strong. Intolerance to light and sound is a prominent feature. The skin becomes hypersensitive and a petechial rash appears, hence the synonym—spotted fever. Trophic changes may occur and herpes is common. This is generally a leucocytosis. To test for the distinctive Kernig's sign, the patient lies with the thighs flexed upon the abdomen and the legs flexed upon the thighs; if meningitis is present extension of the legs is impossible, being prevented by the contraction of the hamstrings. Delirium is present usually from the onset, and may be so prominent as to give rise to maniacal outbreaks. The urine is high-colored, scanty, and may contain albumin. Late in the disease it may be passed involuntarily. Occasionally the joints may be swollen." *Treatment:* "Rest in bed, liquid diet, ice-bags to the head, and counterirritation to the back are essential. Pain and restlessness are relieved by morphine, the bromides and chloral. The bowels should be freely opened, and the bladder should be emptied by catheterization, if necessary. The fluidextract of ergot, gtt. 10-20, may be given. Lumbar puncture and laminectomy are sometimes necessary. Alcohol, digitalis and quinine are of value. During convalescence potassium iodide, tonics, rest and quiet, massage, and electricity are indicated. In case of epidemic cerebrospinal meningitis the serum treatment should be resorted to."—(*Pocket Cyclopedia of Medicine and Surgery.*)

SYMPTOMS OF TUBERCULOUS MENINGITIS. "*Prodromal:* The child usually shows more or less definite symptoms of the tuberculous diathesis, such as emaciation, want of appetite, or constipation alternating with diarrhea. Irritability of temper and headache are perhaps the most common features previous to the onset of definite symptoms of the meningeal affection. Such a condition may last a few weeks or months. *Irritative Stage.*—The symptoms are similar to those of the simple variety, but the head is usually more retracted and the neck more rigid; the abdomen is hollowed out or boat-shaped; the temperature oscillates; internal strabismus or other paralysis of cranial nerves may be present, and there is often marked vasomotor paralysis, manifested by the *tache cérébrale* (a red line upon the skin rapidly following a stroke of the finger nail). This, however, is not diagnostic. Vomiting is very constantly present, and may or may not be related to food. The pulse is irregular and slow. This stage continues for a week or so. *Compression Stage.*—The pulse becomes more rapid with the exhaustion of the heart, the symptoms that accompany coma develop, and death may take place in from ten days to six weeks from the onset of acute symptoms. In the *adult* delirium may take the place of convulsions. The course of the disease is more rapid than in children, as the skull cannot expand, and hence intracranial pressure develops more quickly."—(Wheeler and Jack's *Handbook of Medicine.*)

7. *Displaced apex-beat may be due to:* Pericardial effusion, distention of abdomen, pleural effusion, dilatation or hypertrophy of the heart, emphysema, aneurysm of arch of aorta, mediastinal tumors, hydrothorax, pneumothorax.

For physical signs of dilatation and hypertrophy of the heart, see QUESTION 5.

8. HERPES ZOSTER: *Diagnosis* is made by the pain, and eruption along the course of a cutaneous nerve (generally one of the intercostal nerves); it is generally unilateral; the vesicles show no tendency to rupture. *Treatment:* Flexible collodion or a dusting powder locally, to protect the vesicles; antipyrin or phenacetin or morphine for the pain, and zinc phosphide and nux vomica as a nerve tonic.

The gonococcus or some other pyogenic microorganism is the cause of most cases of early blindness. *Preventive treatment:* Whenever there is the possibility of infection, or in every case, wash the eyelids of the newborn child with clean warm water, and drop on the cornea of each eye one drop of a 1 per cent. solution of nitrate of silver, immediately after birth.

OBSTETRICS.

1. The *bones* of the pelvis are: Innominate (consisting of ilium, ischium and pubes), sacrum and coccyx; the *divisions* are true and false pelvis; the *straits* are superior and inferior; the *symphyses* are pubic, sacroiliac and sacrococcygeal.

The chief differences between the male and female pelvis are thus tabulated in Morris's *Anatomy:*

MALE.	FEMALE.
Bones heavier and rougher.	Bones more slender.
Ilia less vertical.	Ilia more vertical.
Iliac fossæ deeper.	Illiac fossæ shallower.
False pelvis relatively wider.	False pelvis relatively narrower.

MALE.	FEMALE.
True pelvis deeper.	True pelvis shallower.
True pelvis narrower.	True pelvis wider.
Inlet more heart-shaped.	Inlet more oval.
Symphysis deeper.	Symphysis shallower.
Tuberosities of ischia inflexed.	Tuberosities of ischia everted.
Pubic arch narrower and more pointed.	Pubic arch wider and more rounded.
Margins of ischiopubic rami more everted.	Margins of ischiopubic rami less everted.
Obturator foramen oval.	Obturator foramen triangular.
Sacrum narrower and more curved.	Sacrum wider and less curved.
Capacity of true pelvis less.	Capacity of true pelvis greater.

2. The *internal female organs of generation* are: Ovaries, Fallopian tubes, uterus and vagina.

The virgin uterus is about three inches long, about two inches wide at the upper part, and about one inch thick; it weighs about an ounce, or an ounce and a half. The uterus lies between the rectum behind and the bladder in front; it is below the abdominal cavity and above the vagina. Its position is one of slight anteflexion, with its long axis at right angles to the long axis of the vagina. The anterior surface of its body rests on the bladder, and the cervix points backward toward the coccyx. The uterus is not fixed, but moves freely within certain limits. It is held in place by ligaments—broad ligaments, round ligaments, vesicouterine and rectouterine. It is pear-shaped; its cavity is very small; it is divided into fundus and cervix; besides the opening at the os there is an opening on each side near the fundus leading into a Fallopian tube; it is lined by mucous membrane, and covered by serous membrane. The nerves are from the hypogastric and sacral plexus, and from 3d and 4th sacral nerves. The arteries are the uterine and ovarian.

3. *Menstruation* is a periodical disturbance in the female, characterized by a bloody mucus discharge from the uterine cavity; it lasts during the period of woman's sexual activity, but is temporarily suspended during pregnancy and early lactation.

A woman usually menstruates about two or three months after her confinement if she *is not* nursing her child, and about seven months after the confinement if she *is* nursing her child.

4. *During pregnancy* the uterus increases in *size* (from 3 to 12 inches in length; from 1½ to 9 inches in breadth), in weight (from about one ounce to two pounds, not including its contents). The cavity is enlarged over 500 times. All the tissues, muscles, ligaments, arteries, veins, lymphatics, and nerves become tremendously hypertrophied. The uterus also changes its position; at first it drops, later it gradually rises, till just before labor (when it again drops).

VIRGIN UTERUS	UTERUS OF MULTIPARA
The cavity is of normal length and triangular.	The cavity is increased in length and oval.
The cervix is small, hard, and cartilaginous, and of the same length as the body.	The cervix is large and soft; it is about one-half the length of the body.
The external os is a transverse slit or pinhole orifice with smooth edges.	The external os is irregular and its edges are fissured.
The sides of the cavity of the body are convex inward.	The sides of the cavity of the body are convex outward.
The uterus is normally anteflexed.	The uterus is straighter, or even retrodisplaced.
There is more or less flattening of the anterior and posterior uterine surfaces.	The contour of the uterus is more rounded, while its diameters are increased.
The fundus is nearly flat	The fundus is convex.
The internal os is closed.	The internal os is patulous.

—(From Dorland's *Obstetrics.*)

5. As a rule a diagnosis cannot be made till the pregnancy is nearly half over, and the most skilful can hardly obtain absolutely positive signs during the first sixteen weeks.

Positive signs of pregnancy: (1) Hearing the fetal heart sound; (2) active movements of the fetus; (3) ballottement; (4) outlining the fetus in whole or part by palpation, and (5) the umbilical or funic souffle.

5.—

PREGNANCY.	OVARIAN TUMOR.
The usual signs of pregnancy are present.	There is an absence of the chief sign of pregnancy, as a general rule.
The patient is generally in good health, with an increase of body-weight; there is no characteristic facies.	In advanced cases the ovarian facies is present—a pale, drawn expression, with yellowness of the skin and general emaciation.
The abdominal tumor is hard- non-fluctuating, situated in the median line, and reveals the fetal signs.	The abdominal tumor is soft, fluctuating, showing usually more or less growth to one or the other side, and does not reveal the fetal signs.
There is generally a suppression of menstruation.	Continuance of menstruation is the rule, although it may be altered in character; suppression has been noted.
The cervix is soft (Goodell's sign).	The cervix is probably not altered.
There is history of exposure to the possibility of impregnation, with rapidly-developing enlargement in the median line.	The history is obscure, with a slowly-developing tumor beginning on one or the other side.

—(Dorland's *Obstetrics.*)

Pregnancy: The tumor is hard and does not fluctuate, is situated in the median line, and may give fetal heart sounds and movements; the cervix is soft, and the other signs of pregnancy are present. The rate of growth of the tumor and the general condition of the patient's health may also help in arriving at a diagnosis.

Uterine fibroid: Menstruation is irregular and sometimes very profuse; absence of the signs of pregnancy; the tumor is nodular, firm, irregular in outline, and while generally placed somewhat centrally is not in the median line, and is not symmetrical; the rate of growth is irregular, being, as a rule, slow, and sometimes extending over years.

Ascites: Absence of the signs of pregnancy; the abdomen is distended, but the shape varies with the position of the patient; on lying down there is bulging at the sides, the tumor fluctuates, and percussion shows dullness in the flanks, with resonance in the median line, but the dullness varies with the position of the patient.

Gas: Absence of signs of pregnancy; the uterus enlarges more slowly than in pregnancy, and when large enough is resonant on percussion and lighter to the palpating finger in the vagina.

6. *Before Labor:* "Comparatively little can be accomplished by any specific treatment of the breasts and nipples, except frequent bathing to prevent the accumulation of crusts from the drying of the secretion which in many instances is considerable. Small and slightly protruding nipples may be lengthened somewhat by gentle traction practised two or three times a day during the latter part of pregnancy. Nipples that are markedly retracted cannot be appreciably improved. Daily bathing with a mild solution of alum in 50 per cent. alcohol will help to harden them and thus aid in the prevention of fissures during the puerperium."—(Jewett's *Obstetrics.*)

"*After the birth*, the nipples need special care to prevent the formation of fissures. The nurse should cleanse the nipple before and after each nursing with a bland antiseptic solution such as a saturated solution of boric acid, to which one-eighth (⅛) part of glycerin has been added; while before each nursing the child's mouth should be cleansed in a like manner with a saturated solution of boric acid, care being used to avoid injury to the buccal epithelium from too vigorous handling. Excessive nursing must not be permitted, for the nipple is injured by long continued maceration, and avenues for infection are opened. The nurse must be warned of the risk of carrying infection to the nipples or to the child, when her hands are soiled from handling the lochial guard. The nipple should never be touched by the nurse until she has first thoroughly disinfected her hands."—(Polak's *Obstetrics.*)

7. *To facilitate a tedious or painful labor:* Remove the cause, if possible; see that the bladder and rectum are empty; rectal injections of glycerin; pituitrin, strychnine, quinine or other stimulants may be administered; uterine massage may be tried; the patient may assume the semi-recumbent or squatting posture during the pains.

8. They should not undertake any obstetric work without having taken more than the ordinary antiseptic precautions. A thorough bath, use of antiseptics, and clean clothes should form part of this care.

SURGERY.

1. The patient feels a snap at the time of injury, and suffers from pain, increased during inspiration. If the back is fixed and the sternum firmly pressed back, pain is felt at the middle of the rib. Crepitus may or may not be felt. *Complications:* Puncture of pericardium, pleura, heart, lung, or other viscera; emphysema; pneumothorax; pyothorax; pleurisy; pneumonia.

Treatment: Strips of plaster reaching from the spine to the sternum should be placed over the injured side during deep inspiration. The strips should overlap, and a bandage should be put on over the plaster. If the fracture is due to direct violence, no strapping should be used, but the patient kept still by placing sand-bags on either side.—(*Aids to Surgery.*)

2. *Toxemia or sapremia* is due to absorption of toxins only.

Septicemia is due to organisms multiplying in the blood.

Pyemia is due to particles of blood-clot carrying organisms to parts distant from the original source, and there setting up abscesses.

3. *Etiology:* Infection from nasopharynx or ear, exanthemata, grippe, inflammation of middle ear. *Symptoms:* Tenderness, pain, swelling, and redness over the mastoid; bulging of the superior and posterior parts of the auditory canal; temperature variable, from normal up to about 104° F. *Treatment:* Hot water, or cold water, or ice; leeches; purgatives; light diet; acetanilid; incision, or mastoid operation. *Operation:* A semicircular incision of the soft parts is carried from a point about one-half inch above the attachment to the auricle, backward and downward, keeping parallel to the auricular attachment and terminating at the tip of the mastoid. The periosteum is now elevated or dissected from the bone and the osseous structure thoroughly exposed by means of retractors, which are held by an assistant, the auricle being pulled forward so as to lie upon the side of the head. The hemorrhage is controlled by the use of hot sponges and artery forceps. The surface of the mastoid is thoroughly examined for areas of necrosis or the existence of a fistulous opening, especially if a fluctuating swelling obtains previous to the operation. If these exist, the openings are enlarged by means of a gouge or a chisel and mallet, and followed inward to their origin. Should the surface present a healthy appearance, the primary opening of the mastoid is made into the antrum by means of the chisel, the point of entrance being effected just below the line of the superior wall of the meatus and about one-quarter of an inch backward from the posterior wall or anterior edge of the mastoid bone. When the antrum has been exposed, the cortex of the mastoid is chiselled away from this point downward toward the tip until a sufficient amount has been removed to expose all parts of the mastoid process. The cells are now all broken down, and every vestige of a necrotic or granulating area is completely eradicated. A free communication of the antrum with the tympanum should be established, which may be proved by syringing an antiseptic solution into the antrum, when it will escape from the external auditory meatus through a previous perforation of the drumhead. The cavity of the mastoid is packed with sterile gauze, and the flaps of overlying tissue allowed to regain their former position, when a gap remains between their edges, through which the dressings may be changed.—(From Alling and Griffin's *Epitome on Eye and Ear.*)

4. In a *simple fracture*, there is history of the injury, disability, deformity, pain, false point of motion, and possibly crepitus; in *compound* fracture, in addition to the above, there is an open wound leading down to the site of fracture; in *comminuted* fracture, the bone or bones are broken into small pieces. Constitutional effects (due to hemorrhage, shock, sepsis, or other complications) may follow. *Treatment of simple* fracture: First of all, prevent it from becoming compound, then reduce it, coapt the edges of the broken bone, immobilize the parts, and attend to the general condition of the patient. In *compound* fractures: Give an anesthetic, thoroughly asepticize the parts, stop the hemorrhage, remove loose fragments of bone, fix the bones, drain, and immobilize; the wound wants careful antiseptic treatment. The leg must be flexed on the thigh to aid in reducing the fracture, and it may be necessary to cut the tendo Achillis. Splints will be necessary.

5. The damages produced by dislocation are tearing of the capsule and surrounding muscles, and perhaps fracture of the cartilaginous or bony surfaces. The joint and surrounding soft tissues are infiltrated with blood. Vessels and nerves in the neighborhood may be contused or compressed. If allowed to remain unreduced, the displaced head becomes surrounded by a false joint capsule, the true articular cavity becomes filled up with fibrous tissue, and the muscles and tendons around become shortened, while adhesions to big vessels close at hand constitute a danger in attempted reduction.

Treatment: All dislocations should be reduced in the earliest stages, either by manipulation or extension. Manipulation aims at making the bone retrace the course by which it left its proper position. Anesthesia renders this very easy by overcoming the spasmodic contraction of the muscles. Extension is employed to overcome muscular contraction. The hands, a jack-towel, and pulleys are used for this purpose. The reduction is usually marked by a distinct snap. The bones are then felt to be in their normal relation, and normal mobility is restored. Rest for a few days and early passive movements soon repair the damage done. —(*Aids to Surgery.*)

6. *Malignant tumors* are not encapsulated, tend to infiltrate the surrounding tissues, give rise to metastatic growths, have a tendency to recur after removal, give a cachexia, have a fatal tendency.

Benign tumors are encapsulated, do not tend to infiltrate the surrounding tissues, do not give rise to metastatic growths, do not tend to recur after removal, do not produce cachexia, and do not have a fatal tendency (except from their location.)

Two malignant tumors: Carcinoma and sarcoma.

Two benign tumors: Fibroma and lipoma.

7. The *symptoms* consist of aching pain in the loin and frequent micturition. Hematuria comes on early and without apparent cause, is not increased by movement or improved by rest. Pus is usually present in acid urine, and the *Bacillus tuberculosis* may in some cases be detected. In the late stages the kidneys may be felt much enlarged. The *diagnosis* is doubtful in the early stages, unless bacilli can be demonstrated by the microscope or inoculation of a guinea-pig. The hematuria is much slighter than in cases of renal calculus, and is not influenced by rest. The hemorrhage is not so profuse as in cases of new growth. Slight attacks of renal colic may occur from the passage of caseous matter, but not severe attacks like those due to calculus. An exploratory incision settles the diagnosis in doubtful cases. *Treatment:* If on exposure of the kidney a limited portion is found to be diseased, a wedge-shaped portion is excised. If, as is more usual, the kidney is extensively affected, two methods may be adopted: (1) If the other kidney is healthy, nephrectomy with removal of as much of the ureter as possible is done. (2) Nephrotomy, followed by drainage, is done when the patient's condition is bad.

8. ERYSIPELAS. *"Etiology: Predisposing causes:* (1) A wound or abrasion; (2) constitutional debility; (3) bad hygiene. *Exciting cause: Streptococcus erysipelatis,* which is indistinguishable from *S. pyogenes.*

Symptoms: Malaise with rigor and headache. Rash appears within twenty-four hours; it appears first round the wound, which breaks open; it is of a vivid red color, which fades on pressure. Pain and swelling are not much marked. The eyelids and scrotum when affected become very edematous. Vesicles and bullæ form superficially, and a fine desquamation occurs, with some staining of the skin as the rash fades away. Lymphatic glands in the neighborhood are enlarged and tender. The patient is very ill, with high temperature—102°-104° F. Delirium is frequent, especially when the scalp is affected. Vomiting is common.

Varieties: Facial erysipelas is often apparently idiopathic and recurrent. *Faucial erysipelas* spreads from the exterior to the pharynx; causes great swelling of the parts, with a tendency to edema glottidis. *Scrotal erysipelas* causes great edema, and in children a tendency to sloughing. *Cellulo-cutaneous erysipelas* partakes of the character of both cellulitis and erysipelas, affecting the skin and subcutaneous tissue.—(Grove's *Synopsis of Surgery.*)

GUNSHOT AND SHELL WOUNDS.

BY P. C. FAUNTLEROY,

MAJOR, MEDICAL CORPS, U. S. ARMY.

IN order to understand satisfactorily the injuries received in war it is necessary to have some knowledge of the weapons with which they are inflicted.

The accompanying table will show the principal features of the reduced caliber rifles now used by the great armies of the world. The following more detailed information of the rifles and ammunition which are representative of the modern reduced caliber weapons will be sufficient to give a clear understanding of these and the injuries inflicted by them.

The ammunition of the U. S. A. rifle (New Springfield, model 1913) is described as 0.3083 inch diameter, pointed, lead core, with cupronickel jacket, weight 150 grains, length 1.08 inches; 47 to 50 grains of pyrocellulose powder; 2,700 feet per second initial velocity of translation; 3.240 turns per second velocity of rotation at muzzle; effective range, 4,891 yards; energy, 2,400 foot-pounds. It has a penetration of 33 inches white pine at 50 yards, 24 inches at 500 yards, and 12 inches at 1,000 yards; 12 inches moist, 7 inches dry sand, and 18 inches loam at 1,000 yards; 5 inches brick wall at 100 yards. This ammunition is used in the automatic machine gun also. Our new 1903 Springfield rifle has a point blank range from a standing position of 718.6 yards. It is sighted to 2,850 yards. This is one of the most effective of all military rifles. It weighs 8.69 pounds and with the bayonet is 4 feet 11 inches long. Its magazine holds five cartridges.

The new German Mauser has a caliber of 0.311 (7.9 mm.), using a pointed bullet 0.323 inch diameter, weight 154.3 grains, with a charge of 49.3 grains of smokeless powder. Its muzzle velocity is 2,952 feet per second and it has an effective range of 5,465 yards. It weighs 9.03 pounds and with the bayonet is 5 feet 10 inches long. Its magazine holds five cartridges.

The Turkish rifle (model 1893) is a Mauser, 0.301 inch (7.65 mm.) caliber, using a clip of 5 rimless cartridges (model 1907 and 1908). The bullet is sharp pointed, with lead core, steel nickel-plated mantel, length 1.075 inches; 0.311 inch diameter; weight, 154 grains; density, 334 grains per square centimeter or 0.155 square inch. The cartridge is charged with 45½ grains smokeless powder in flakes and develops a muzzle velocity of 2,788 feet per second and a muzzle energy of 2,661 foot-pounds. It weighs 8.59 pounds and with the bayonet is 5 feet 6 inches long.

The English are equipped with the Lee-Enfield (1907), the magazine holding 10 cartridges, caliber 0.303 inch, using a sharp pointed bullet with lead core and cupronickel mantle; weight, 215 grains; smokeless powder, 31.5 grains; muzzle velocity, 2,060 foot-seconds. It weighs 9.25 pounds and with the bayonet is 5 feet 1 inch long.

For comparison with similar weapons used still by some nations the following description is given of the U. S. Krag-Jorgensen rifle: Caliber, 0.30 inch (7.62 mm.); clip 5 cartridges; bullet, 0.308 inch diameter; length, 1.26 inches; weight, 220 grains, lead core, cupronickel steel mantle. Charge 35 to 42 grains nitrocellulose powder, initial velocity, 2,000 feet per second; velocity of rotation at muzzle, 2,400 turns per second. Muzzle energy, 1,954 foot-pounds. Penetration in seasoned oak across grain, 19.5 inches at 50 feet. Weight, 9.19 pounds.

Examination of the table indicates that in effectiveness the rifles used in the late Balkan War stand in the following order: Turkey, Greece, Servia, Bulgaria.

The Colt automatic pistol, United States Government model, is superior to any other pistol or revolver. Caliber, 0.45; magazine holds 7 cartridges; bullet, 0.45 caliber; length, 0.66 in; lead core; cupronickel mantle; weight, 230 grains; charge, 5 grains smokeless powder; initial velocity, 900 foot-seconds.

The two classes of smokeless powder usually found in use are: Nitroglycerin powder, used for hand weapons, and nitrocellulose powder, used in both small arms and cannon. Both are made from gun cotton, but the first has from 10 to 30 per cent. of nitroglycerin. A nitroglycerin powder, from the high temperature of explosion, causes greater erosion of the metal of the bore, and thus shortens the life of the large costly guns, hence it is that nitrocellulose is preferred for cannon.

The United States Army is equipped with field artillery of the following caliber: 3-inch field gun, mountain, and howitzer; 3.8-inch gun and howitzer; 4.7-inch gun and howitzer, and 6-inch howitzer. These are the usual calibers found in the field artillery of the great nations. The extreme ranges of these guns vary from 5,600 to 6,704 yards, the weights of the projectiles range from 15 pounds to 120 pounds. The shrapnel contains from 252 to 1,074 round lead bullets, varying from 0.5 inch to 0.6 inch in diameter, each weighing from 167 grains to 306.4 grains. The shell when used breaks up into approximately 600 to 1,500 effective fragments. The area of dispersion on explosion at less than 3,000 yards range, vary for the shrapnel from 400 to 150 yards by 200 to 75 yards, and for the shell, 300 to 100 yards by 150 to 75 yards. Germany is now using an 11-inch howitzer, range 8 miles, weight of projectile 748 pounds, which strikes with an energy of 5,000 foot-tons when fired at an angle of 70 degrees.

In the late Turko-Balkan War, Bulgaria, Servia, and Greece were equipped with a Schnider-Creusot quick-firer, 2.95-inch caliber; 13-pound projectiles; range, 7,665 yards. Turkey used a Krupp quick-

firer, 2.95-inch caliber; range, 8,700 yards. Both sides used a Krupp quick-firer field howitzer; caliber, 4.72 inches. The French gun is superior to the Krupp because of its independent line of sight, steady carriage, and free recoiling gun, which does not jump back and does not have to be relayed after firing. Its only drawback is it is somewhat heavy and has a small shield. Five hundred rounds of fixed ammunition is carried in the field for each gun.

Shrapnel forms 80 per cent. of the ammunition supply of the field guns and is thus the principal projectile of all modern field artillery. The old solid shot shell, cannister, and case shot, are no longer used in modern guns. The modern so-called solid shot is now hollow with thick walls and is used principally to perforate armor. Modern shrapnel is used against troops in masses and material as well.

The United States Army 3-inch field gun is supplied with shrapnel which is described as a steel tube with solid base and detachable head in which there is a time fuse. It contains a bursting charge of $2\frac{3}{4}$ ounces of black powder at the base. There is a stopper of gun cotton in the central tube to hold the powder in place and to assist in the explosion. There are 862 round balls of 0.50-inch caliber composed of lead, hardened with antimony. The balls are surrounded by a smoke producing matrix which is used to locate the point of bursting. The shrapnel is said to be a man-killer at 6,500 yards. At the latter distance the shrapnel has a remaining velocity of 565 feet per second. On bursting an additional velocity of 300 feet per second is conferred on the lead bullets, making altogether a velocity of 865 feet per second at 6,500 yards. The fuse can be cut to cause the projectile to explode at any one-sixth of a second in the flight. Its weight is 15 pounds; length, 10 inches; initial velocity, 1,700 feet per second. The number of effective fragments on bursting is said to be 1,200. The area of dispersion is about 150 yards wide and 400 yards long at a range less than 3,000 yards.

Hand grenades, hand bombs, mines, and torpedoes figure largely in modern combats both on land and water. They are charged with high explosives and are used against troops and material. Their action is principally rending.

The bayonet and saber are to be found in every thoroughly equipped modern army. From the nature of hand-to-hand conflicts wounds by these weapons are extensive, lacerated, and usually fatal. Only the very slight ever reach the hospitals. The bayonet varies from the well-known, long, entirely thrusting instrument, with a triangular cross section, to the long sword and short knife bayonets used both for thrusting and cutting. The saber is a most effective weapon in the hands of the properly trained officer and soldier. It has been said that these weapons no longer have a place in modern armies, equipped with the long range, high-power magazine rifle and automatic magazine pistol. But such arguments have grown out of mistakes made as to the proper time and place to make use of them. No decisive victory over trained troops is ever won until the attack is pushed home with the bayonet and saber; and if made at the psychological moment, that is when the enemy is already badly shaken by rifle and artillery fire, it is most effective and complete.

The above remarks are made largely to warn the beginner against falling under the influence of the misguided, and in consequence neglect to study the injuries inflicted by these weapons.

It will be found useful for purpose of comparison to give the principal features of the old muzzle-loading rifles:

Minie rifle, 1851 to 1866, corresponding to early Springfield rifle, caliber, 0.702 inch; bullet diameter, 0.69 inch; weight, 680 grains; charge of powder, 150 grains; sighted for 100 to 1,000 yards.

Springfield rifle, 1865, caliber, 0.58 inch; weight of bullet, 500 grains; charge of powder, 80 grains.

Breechloaders have been known for several hundred years, but not until the Austro-Prussian War, 1866, was practical use made of them on a large scale. In 1866 the United States converted its muzzle-loading Springfield to a single-shot breechloader and at the same time it reduced the caliber to 0.50 inches. In 1873 the caliber was further reduced to 0.45 inch, weight of bullet 500 grains, and 70 grains of powder used. This gave a muzzle velocity of 1,301 foot-seconds, point blank range of 350 yards, and maximum effective range of 2,000 yards, penetration of about 3 inches in well-seasoned oak across the grain at 50 feet. Many nations today equip certain classes of their reserves with a similar weapon.

Ballistics.—The old round balls, fired from smooth bore guns, had only the forward motion, *i.e.* motion of translation. In order to increase the velocity of the bullet and thereby obtain a flatter trajectory and increased danger zone, it was found necessary to cut spiral grooves in the bore of the gun and to lengthen the bullet. The latter changes gave the bullet a rotary movement in addition to its movement of translation. The velocity with which the bullet leaves the muzzle of the gun is due to the expansive force of the powder-gases generated by the explosion of the charge of powder. A short way from the muzzle of the gun these gases cease to act and the bullet goes forward with a certain velocity, which is affected by the well-known laws of air resistance or friction and gravity.

From the combined effect of the air resistance and that of gravity, the line of flight of the bullet is curved and its velocity grows less and less until finally it comes to rest on the earth's surface.

The motion of rotation is given to the bullet to steady it in its flight and prevent its tipping and tumbling when it begins to take a downward course and the resultant air resistance becomes oblique to the axis of the bullet. This motion is caused by the bullet engaging with the grooves or rifling, as it passes through the bore and continues for some time after the forward movement ceases. The velocity of rotation depends on linear velocity and the twist of the rifling. The United States 0.30 caliber rifle has a right-hand twist of 1 turn in 10 inches. Owing to the twist and to air resistance the United States rifle bullet drifts towards the right 13 inches in 1,000 yards, 61 inches in 1,500 yards, and 148 inches in 2,000 yards. To counteract the effect of this inevitable drift from the vertical plane the slot in the rear sight is placed slightly to one side of the middle line of the rifle barrel.

The effectiveness of rifle fire is proportionate to the flatness of the trajectory. From what has been said it will be seen that the flatness of the trajectory is in proportion to the velocity of the bullet. A flat trajectory is due to high muzzle velocity and low air resistance. Muzzle velocity depends upon the powder charge, the gas pressure, and weight of the projectile. It is limited by the permissible energy of recoil and the strength of the gun. The rifle must not be too heavy and the recoil too great to injuriously affect the soldier's shooting. The projectile must not be too light lest it have insufficient man stopping power or shock effect. It will be readily seen that the greater the sectional density of the bullet the less it will be affected by air resistance. That is by increasing the weight of the bullet and diminishing its diameter the less the air resistance and therefore the flatter the trajectory.

The air resistance can further be reduced by improving the form of the projectile, *i.e.* making it pointed.

The force with which the projectile strikes can be calculated by the well-known formula: $F = \frac{mv^2}{2}$

The ability of a bullet to penetrate a body is proportional to the square of its velocity, and for bullets of equal velocities, it is proportional to the density of section. The force and strength to resist deformation have a great influence in this regard.

In view of the use of air-craft for dropping explosives, arrows, and bullets on the enemy, it may be mentioned that a shrapnel bullet (20 to the pound), dropped from a height of 3,000 feet, would reach the ground with a velocity of 450 feet per second with a force of 160 foot-pounds. Dropped from a distance of 1 mile they would reach the ground with a velocity of 630 feet per second. A force of 60 foot-pounds is sufficient to kill a man. On the other hand the service rifle will send a bullet a mile high in less than 6 seconds and with sufficient force to kill the aviator or severely damage his machine.

Gunshot Injuries.—It may be said in general that the wounds inflicted by the projectiles of the modern firearms are not so extensive in their pathological features as they were from the older weapons, and also that their treatment is correspondingly less difficult.

Let us consider the effects of the old time, larger and lower velocity projectiles, for by comparison with those of the modern, small steel-jacketed, high-velocity bullet we can then better understand the characteristic appearance of bullet wounds in general.

The old round musket balls were of soft lead and from 0.702 to 0.75 inch in diameter. Their initial velocity was from 600 to 700 feet per second.

The destruction of the soft tissues by these round

balls of low velocity was in proportion to their diameter; their mechanical effects being, the tissues were stretched, as it were, to permit their passage.

The wound of entrance was about the size of the ball, the wound giving the impression of having been punched out. An extensive ecchymosis surrounded the wound. This ball occasioned a track of devitalized tissue greater than its diameter. The wound of exit was irregular in shape, with everted edges, and always larger in the skin than that of the entrance.

On striking bone this ball usually flattened itself and nearly always remained in the tissues. Although this round ball, at its maximum velocity, could occasion great damage, the conoidal bullets of a later date occasioned much more extensive injuries. Extensive comminution and displacement of the splinters of bone in the track, was caused by the force of impact of the bullet. The shaft of the bone above and below the seat of the fracture was fissured. The extensive devitalization of the soft parts, together with extensive damage to the bone, offered a field with little resistance to infection and extensive suppuration. To these pathological characteristics must be attributed the great danger to life occasioned by these old round bullets.

The Cylindroconoidal Bullet.—The earlier types of this bullet were used in the so-called Minie rifle. As these guns became more perfect the velocity of the bullet increased to 1,300 feet per second and the energy to 1,879 foot-pounds, with the result that wounds made by these conoidal bullets were marked by such enormous destruction of tissue that until the mechanics of the projectile were properly understood, the beginning of every war was marked by accusations of the use of explosive bullets. Owing to the great so-called "explosive effect" of the modern small caliber high-power ammunition similar accusations were common at the beginning of the recent wars.

The increase of the velocity of the bullet has always been the aim of those seeking to perfect the military weapon. Perfect and close-fitting of the bullet in the barrel was first adopted to bring about this result, which was clearly due to the tightly fitting bullet preventing the escape of the powder gases. To best effect this result necessitated the discarding of the smooth bore, large caliber musket for the rifled bore weapon. It was found that the change increased the recoil so greatly in the large caliber weapons that the accuracy of the soldier's shooting was seriously affected, even if he was not actually incapacitated thereby. This led to the reduction in caliber which not only reduced the recoil but increased the penetrating power of the bullets. The reduction in the size of the bullet brought about a corresponding reduction in the severity of the wounds. There was less contusion and laceration of the soft tissues and the extent to which the tissue surrounding the track was devitalized was less.

The effect produced by the 0.45 caliber cylindroconoidal bullet striking resisting bone, such as the shaft of the long bones of the upper or lower extremities, gave the impression that an explosion had taken place in the wound. Such explosive effects were only seen in the close ranges, say 350 yards. Within this range the wound of entrance, if the skin immediately overlaid the bone, often contained bony sand; otherwise the wound of entrance possessed no special features.

The pulverization at the point of contact in hard bone occasioned a loss of substance. The bone immediately at this point was minutely comminuted, and running from it there were many radiating lines of fracture, thus splintering the bone in first small and then larger fragments, some of which being entirely detached and driven ahead of the bullet, or at different angles to the track, and thus became really secondary missiles. These particles of bone, together with particles of the bullet, having acquired an energy in proportion to the velocity of the bullet, occasioned great destruction of the soft tissues, ahead of them, and a large, ragged, irregular wound of exit, several times larger than the diameter of the bullet. These missiles gave rise to a conical shaped wound-track having its apex at the seat of the fracture and its base formed by the wound of exit. It may be noted here, that this explanation of the cause of the so-called explosive effects of bullets when bone fragmentation occurs, also explains similar effects when organs or cavities containing fluid are penetrated at high velocities,—the particles of water or fluid masses being driven outward in all directions with an energy in proportion to the velocity of the bullet and thus become secondary missiles and rend the tissues in all directions. As the distance increased beyond the proximal ranges the wounds occasioned became less and less marked by these so-called explosive appearances; there was less comminution and less displacement of fragments and no bone sand.

The wound of exit was always larger, however, than the wound of entrance and when noted was a very reliable indication that some bone injury had taken place. At close ranges, however, there was a greater amount of bone dust and hence greater loss of bone tissue and considerable fragmentation on striking the softer epiphyseal ends, but less displacement of these fragments than when the hard shaft was struck, the shaft was little, if at all fissured. Beyond 350 yards these bullets tended more and more to simply penetrate the soft ends of bone without occasioning splinters or fissures.

These effects are explained by the well-known fact that the effects of bullets in bony tissue are always in proportion to the velocity, sectional area of bullet, deformation, and resistance met, in the order of their importance.

Having considered the wounds occasioned by the old large caliber round and elongated lead bullets of low velocity, we are better prepared to understand the effects of the modern small caliber, steel-jacketed, high-velocity projectiles of modern weapons.

It may be said in a general way that the effects of these bullets differ as they occur in one of four zones:

In the first zone (0 to 500 yards) we see explosive effects.
In the second zone (500 to 1000 yards) we see penetrating effects.
In the third zone (1000 to 2000 yards) we see simple wounding effects.
In the fourth zone (2000 to 2500 yards) we see contusive wounding effects.

With two bullets of the same caliber and weight but with unequal velocity, the shock occasioned will always be the greatest with one of greater velocity. But notwithstanding the far greater velocity of the smaller, modern, reduced-caliber projectile, the shock occasioned within the effective range of the respective weapons, it is far less in the case of the modern smaller bullet than that which obtained with the old larger caliber lead bullet of slower velocity. This is due to the fact that while the velocity is the most potent of the factors in producing the so-called explosive effects, and is about double in the modern bullet to that of the older ones, the energy has not

correspondingly increased because of the reduction in sectional area and weight. This gave rise to serious objections on the part of military men, but experience in four wars has shown that except in the case of savages and animals, the shock is quite sufficient to cause the soldier to stop and fall to the rear.

The vastly increased velocity, greater penetration, far greater accuracy, and increase in the danger zone from the flatter trajectory brought about by the reduction in caliber, can, however, be carried to such an extent as to reduce the stopping power of the weapon below the requirements of modern civilized warfare, when the weight of the bullet is likewise reduced. The changing of the ogival point of the modern bullet to a sharp point, making what is now known as the pointed or Spitz bullet, is the latest modification in the interest of increasing the before mentioned ballistic characteristics of modern high explosive ammunition. This form of bullet was adopted as it was found that atmospheric resistance was so greatly reduced that a much flatter trajectory was obtained and the danger zone greatly increased. This change was at the expense of the shocking or man stopping power, but not below that needed in civilized warfare as was found in the late Turko-Balkan War. This change in the bullet moved the center of gravity well back of the middle point, toward the base, thus reducing the stability of the bullet; so that it immediately tumbles on striking small twigs or like unresisting objects in its flight, also in passing through objects or media of unequal densities, such as the human body. This tumbling which occurs after passing through the abdominal or thoracic walls, results in the production of a slashing wound in the viscera with greater hemorrhage and laceration than obtained in wounds with the more stable ogival-pointed bullets. Wounds in the extremities from these tumbling balls are likewise more lacerated with the frequent occurrence of false aneurysm. Many of these were seen in the hospitals of Bulgaria. A singular one is recalled in which the femoral artery was involved, the ball being found in the artery itself—evidently a ball very much spent by tumbling before striking the soldier. Wounds of the lungs invariably gave pronounced signs of pneumohemothorax.

Within and up to a range of 350 yards the explosive effects of the modern reduced-caliber projectiles are about the same as described in the case of the old large caliber lead bullets.

As has been the case in all the recent wars in which the high explosive, reduced-caliber ammunition has been used, the infrequency of explosive effects seen among the wounded in the hospitals is due to the fact that such effects most frequently occur in the vital organs encased in resisting bony walls, as the brain, or in those containing fluid, as the heart and abdominal viscera, and hence to be found only among the dead on the field, of whom the surgeon rarely has time to make more than a hurried examination; many he will never see.

The small sectional area of these modern ogival-pointed bullets and the still smaller frontage of the Spitz or pointed bullet, cause the wounds in the *soft tissues alone* to have such small wounds of exit and such narrow tracks that they heal up very rapidly. Such clean-cut punctured wounds occur only when the bullet is intact and not deformed with irregular, jagged edges from previously striking or glancing off some hard object such as a rocky surface, or in the case especially of the Spitz bullet, where the bullet is not tumbling. The kindly and rapid healing of such flesh wounds, which form the majority of all battlefield casualties, is shown in the recent Turko-Balkan War by the fact that of 35,000 sick and wounded brought north of the frontier from the early battles around Adrianople, Kirk Kalisse, Lule Burgas, and Tchatalja, 28,000 were discharged from the hospitals within five weeks after admission. Owing to the fact that a large proportion of wounds, seen at the hospitals, were inflicted by tumbling bullets, and to the very frequent occurrence of false aneurysm, it is believed that serious if not fatal hemorrhage occurs more frequently in wounds inflicted by the Spitz bullet than by the ogival-pointed one. The damage, however, to the large vessels was not so extensive in the majority of cases *seen in the hospitals* as to prevent repair by suture, and the continuity of the vessel thus preserved.

Beyond the zone of explosive bullets the fracture occasioned in the shafts of long bones presented larger fragments which did not require removal. Such injuries required only disinfecting, reduction, and fixation. Transverse fractures were seen, there being only two fragments. The epiphysis of the long bones at the kneejoint and such cancellous bones as the os calcis, at these long ranges were simply perforated, and the injury required only disinfection and fixation. The upper ends of the femur and humerus, lower end of the tibia, and both ends of the radius and ulna were usually comminuted. The joints when perforated never required more than turning out of blood-clots, disinfection, and immobilization.

Eighty per cent. of such cases were returned to duty within a few weeks.

The behavior of the small caliber steel jacket bullets at the different ranges is often directly opposite to that which is expected. For instance, clean-cut perforations of the shafts of long bones are seen among wounds inflicted at short and mid-ranges; and again great comminution not infrequently occurs in the shafts of long bones at distant ranges.

It may be said in explanation of these seemingly contradictory findings that the bones of many men, especially the younger ones, have a great amount of animal matter, and are consequently less brittle than those of the older men; and therefore the less resistance met by the bullet in the comparatively softer bones, at short ranges, permits the passage of the bullet without explosive effect. In the cases of the older men and more brittle bones the bullet at long ranges causes great damage, especially as the bullet at these long ranges has become unsteady from loss of velocity and strikes the bone sidewise and thus transfers its energy over a greater area than if it had struck point on. Owing to the change in the position of these bullets at the long ranges, the effect produced in the bony tissues is at first in the short ranges very severe from the high velocity, but in the mid-ranges the effects are less severe because of loss in velocity, and at long ranges the effects become severe again because of the impact being made with the side of the bullet. The wound of entrance made by such tumbling bullets is oval or key-holed, similar to that often made by a ricochet shot.

One was greatly impressed with the large number of gunshot fractures of the skull found in the Bulgarian hospitals and their recovery from the

immediate effects of the wounds. This favorable result was especially noted in those cases which had been operated early and the wounds disinfected and the pressure removed. Notwithstanding the unusually large number of penetrating gunshot wounds of the skull, which recovered under proper treatment from the effects of this modern, high velocity ammunition, it is believed that the majority of skull fractures from such ammunition are immediately fatal on the battlefield. It was frequently noted that transportation of the serious gunshot wounds of the skull invariably increased the gravity of the patient's condition and usually caused a fatal ending.

Within the effective ranges of the respective weapons, the modern small caliber high-velocity bullet lodges far less frequently than the old lead one.

The great frequency with which the Spitz bullet lodged in the Bulgarian wounded is to be explained, probably, by the fact that the Turks fought always from entrenched defensive positions, and the battlefields being rolling, open, barren, and treeless in character, the fire from the Turks became effective at long ranges, say 2,000 meters, when the missile was tumbling and greatly spent therefrom. There being no adequate medical organization with the troops, nor stations for the slightly wounded, the hospitals as far back as Sofia were crowded with injuries of a slight nature, which, having occurred at long ranges, the bullet generally lodged in the tissues, and thus the frequency with which the surgeon encountered the missile is to be accounted for.

Wounds from ricochet shots often showed two or more fragments of the bullet; especially was this true in the case of bone lesions, the impact against the bone being sufficient in some cases to entirely separate the deformed and loosed jacket from the lead core.

These modern, small caliber, steel-jacketed bullets rarely carry foreign bodies, such as pieces of clothing, into the wound. Judged by the very small number of resections and amputations required, the rapid healing of the flesh wounds, and the smaller number of permanent cripples, and the great reduction in the number of those wounded who can honestly be found to have a pensionable disability, it must be said that the modern small caliber, steel-jacketed bullet is far more humane than the old leaden one. It must be said, however, that the new Spitz bullet, from its instability and consequent tumbling, becomes a more dangerous projectile than the ogival-pointed one.

Owing to the greatly increased range of the modern small caliber rifles over the old large bore weapons, there occurs now a much greater number of "slightly wounded" than formerly, and from this many are misled into thinking that the pointed bullet is the most humane one yet made use of, but a thorough study of the casualties will show a greatly increased number of those killed outright.

Wounds Received from Shrapnel Shell.—As has been said, shrapnel have an initial velocity of 1,700 feet per second, and at a distance of 6,500 yards, 565 feet per second. On bursting 1,200 effective fragments are thrown in all directions, each having an additional velocity of 300 feet per second, and are very effective within a zone of 90 feet wide by 60 feet long.

The wound occasioned by the fragments of the shell, as well as that by one of the 0.50 caliber round lead balls, of which there are 262 in each shell, is always a lacerated and contused one. Those occasioned by a fragment of the shell are irregular and of a size varying with the shape and size of the piece. These fragments and balls nearly always lodge in the wound. The character of the wounds made by these missiles is that of a low velocity missile such as described for the old low velocity leaden bullet.

There is always a varying amount of shock from the mere bursting of the shrapnel in addition to that inflicted by the impact of the fragments. This is at times quite serious and when so requires many months to recover from. In wounds involving the bony tissues there are always to be found small flakes of lead which are clearly seen in the Roentgen photographs of such injuries.

When shrapnel burst on striking the ground there are many secondary missiles, such as small stone, wood splinters, and particles of dirt, added to those of the missile itself, and are not only effective in producing wounds, but dangerously contaminate those produced by the shell fragments. It is among the wounded from shrapnel that most of the tetanus cases and gas bacillus infections occur.

These shrapnel were exceedingly destructive in the recent Turko-Balkan war, 20 per cent. of the total casualties among the Bulgarians being due to them, and among the Turks about 33 per cent. of all wounds at Kirk Kalisse and Lule Burgas, and 60 per cent. at Tchatalja.

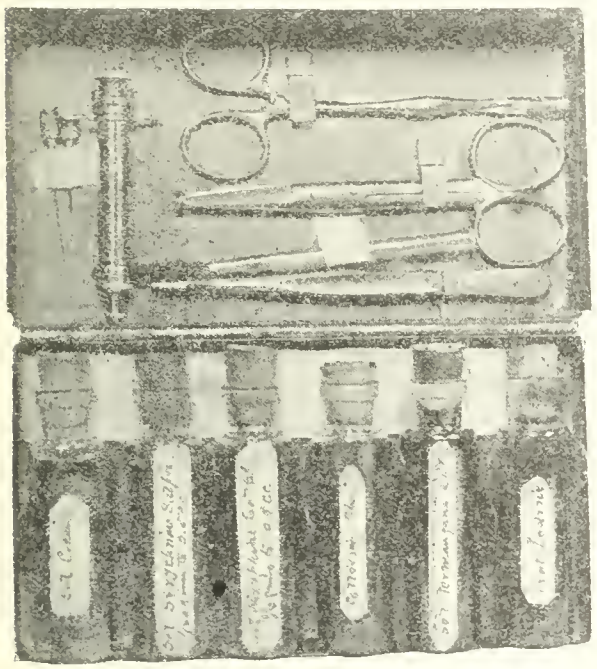
It was among the wounded from shrapnel that the great majority of mutilating operations were found necessary. In some cases seen it was found impossible to save more than a part of any of the four limbs. Fractures of the skull were very frequent from the Turkish shrapnel, and it may be added from the sharp-pointed rifle ball also. These invariably gave a greater percentage of total recoveries and always more rapid convalescence when the wound was properly sterilized and fragments and pressure removed by early trephining. Those not so treated were followed by sepsis, cerebral prolapse, and permanent paralysis, when not by death. Rough transportation in such cases greatly lessened the chances for recovery.

A case was seen of what would no doubt have been called "wind contusion" by the old writers. This was a Turkish infantryman who was injured about 200 meters from the Bulgarian line at Kardoniky October 28, 1912. No wound of any kind was to be found, but he was paralyzed completely below the level of the umbilicus. He was admitted to the hospital in Sofia November 7, 1912; temperature 38° C., and found to have paraplegia and cystitis, the latter having occurred as the result of faulty catheterization. He died two days later, but no lesion was found by the young surgeon who performed the autopsy. This case, as all such cases are now believed to be, was the result of a heavy projectile of low velocity striking him obliquely without occasioning any visible surface injury, but evidently severe injury to the spinal cord. The most pronounced wounds from large projectiles are to be found among the wounded from a naval engagement.

The character of such wounds was very clearly to be seen among 93 wounded Turks resulting from the engagement between the Greek and Turkish fleets off the Dardanelles January 17, 1913. The wounds were marked by extensive laceration of the soft tissues, with great comminution of the bones.

All were badly infected and every man was superficially but extensively burned by the gases from the exploded projectiles and also by hot flakes of lead paint, said to have been driven in from the great impact of the Greek projectiles on the outside of the ship, and from the hot paint scattered from the inside by the bursting of the projectiles inside the ship. These flakes of hot lead stuck to the skin. The majority of deaths were said to have occurred from suffocation by the extremely hot gases from the exploding projectiles. One 10-inch shell is said to have killed 18 and wounded 37 Turks.

Observations among the Bulgarians and later among the Turks confirmed the belief from previous experiences that a medical officer of a moving command cannot depend on having any medical or surgical supplies on the battlefield in time other than those which he carries on his immediate person. This belief led me to improvise before the campaign against Santiago de Cuba in 1898 a *pocket* case containing standard *solutions* of morphine, strychnine, permanganate of potassium, and col-



Pocket-case for use on the battlefield.

lodium, hypodermic syringe, and surgeon's plaster. Later a solution of quinine sulphate was substituted for that of permanganate of potash.

It was found that these previously made solutions were invaluable, saving everybody concerned much time and suffering and extending greatly the zone of the medical officer's activity.

In a report to the Surgeon General of the Army in 1910, attention was invited to the great applicability of tincture of iodine to battlefield casualties, and it was added to the pocket case.

In 1912 a brass metal case was made (of which a picture is here given) containing the before mentioned articles, together with the few instruments needed by the surgeon on the battlefield in the majority of cases. The picture of this case is here shown as a suggestion because of the firm conviction that the regimental surgeon who depends on his orderly always being near him with these solutions or that he can under any circumstances hope to have such necessaries in time of battle, unless he has previously prepared them in such a usable and portable form, will be grievously disappointed and his usefulness greatly curtailed.

The modern method of treatment of gunshot injuries in the immediate rear of the firing line permits little more than the sterilization of the skin, the wound, and protruding bones with tincture of iodine, or a 1:500 alcoholic solution of corrosive sublimate, and a *sterile* occlusive dressing. If there is a bone or joint injury or if the soft parts are extensively involved, there should be a reduction of the deformity so that the part can be immobilized properly and with safety and comfort to the patient. Hemorrhage of course should be arrested immediately by compression and a bandage. After hemorrhage has been arrested, shock and pain should be relieved by means of strychnine and morphine.

The means of meeting these indications are to be found in this small surgeon's field case, and the first-aid dressing carried by the man and the improvisation of splints possible at the scene of accident. If the surgeon's orderly, with his large pouch or the small hospital corps pouch, is at hand, there will probably be ample bandages and splint material and nothing else is needed in the vast majority of cases. At times it will be necessary for the surgeon to remove pieces of clothing, equipment, or gross particles of dirt or splinters by means of the forceps in the case. On still rarer occasions when limbs are struck by large projectiles, it may be necessary to clip with the scissors a small strip of skin, which is the only remaining link by which an extremity is attached. There are many wounds of the face and trunk, which after sterilization, can be securely occluded by means of small pieces of gauze or absorbent cotton, with the flexible collodium or strips of adhesive plaster. The solution of permanganate of potash was put in the case to neutralize the poison of snake-bite wounds and that of the gas bacillus.

Statistics.—The usual ratio between killed and wounded has been 1 to 4 or 5. In the Russo-Japanese war on the side of the Japanese 1 to 3.4. In the Boer war it was on the British side 1 to 3.6.

In the late Turko-Balkan war it is believed that this ratio was much different, and will be found to be for the Turks about 1 to 2.1, and for the Bulgarians about 1 to 2.5. This change was largely due to the large proportion of casualties from shrapnel and the large number dying on the field.

It has been computed that the percentage of casualties for each fighting day during the Civil War (1861-5), Federal, was 4.5 per cent.; Franco-German (1870-1), German, was 4.7 per cent.; Russo-Japanese, Russian, was 1.7 per cent.; Japanese, was 2.0 per cent.

Many of these engagements lasted for many days but the losses were not evenly distributed for each day, and, therefore, such figures do not indicate the conditions which had to be met by the medical service on any one day or at any one place. For instance, some regiments lost 68 per cent., while others lost none. The maximum casualties to be expected are about as follows: For an army corps, 25 per cent.; for a division, 30 per cent.; for a regiment, 60 per cent.

About 70 per cent. of the wounded will be among the infantry and the rest among the artillery, cavalry, etc.

It is of especial interest to note the increasing proportion of casualties due to shrapnel and shell: In the Civil War (1861-5) about one-half of 1 per

cent. of all Federal casualties were due to artillery; in the Franco-German war (1870-1) about 8.4 per cent. of the German casualties; in the Russo-Japanese war about 17 per cent. of the Japanese casualties, and in the Turko-Balkan war (1912) about 20 per cent. of the Bulgarian and 33 per cent. of the Turkish casualties.

It has been stated that the Japanese army casualties in their war with Russia were classified as to weapons as follows: Rifle 76.42, artillery 15.78, bayonet 0.63.

It is said that the

Russians lost, of those that reached the hospitals	3.4% by death
Japanese lost, of those that reached the hospitals	5.8% by death
Germans (1870-1) lost, of those that reached the hospitals	11.0% by death
Federals, in Civil War, lost, of those that reached the hospitals.	13.2% by death
Bulgarians (1912) lost, of those that reached the hospitals	23.0% by death
Turks (1912) lost, of those that reached the hospitals	26.0% by death
Americans (Spanish-American War) lost, of those that reached the hospitals	6.0% by death
English (Boer War) lost, of those that reached the hospitals	8.0% by death

The great improvement in this respect among the Russians and Japanese, English and Americans was due to the better antisepsis on the battlefield, better surgery in the hospitals and to the slight character of many of the wounds inflicted by the reduced caliber rifle.

Nowhere does the result of antisepsis as a factor in the results of war injuries more strikingly appear than in the case of gunshot injuries of the knee joint.

For the Civil War (large caliber *minus* antisepsis) 53.7 per cent. died, amputation was usually performed.

For the Russo-Turkish War (large caliber *plus* antisepsis) 11.1 per cent. died; 28.9 per cent. recovered fit for duty.

For the Spanish-American war (small caliber *plus* antisepsis) none died (American); 81.1 per cent. recovered fit for duty.

From the delay in receiving treatment and the hurried character of the transportation service following large engagements from 40 to 90 per cent. of all wounds will become infected before reaching the stationary hospitals. The wide variation is due to the character of the wounds, the character of the weather, whether wet or dry, hot or cold. The larger percentages of infection occur in winter and among shrapnel wounds. If promptly and properly treated after reaching the hospitals infection can be largely eradicated and bad end results avoided.

Gunshot injuries are distributed about as follows:

	Head	15%	Mortality 51%
	Neck	2%	Mortality 18%
Perforating	Spine	2%	Mortality 75%
Perforating	Chest	4%	Mortality 25%
Perforating	Abdomen	3%	Mortality 65%
	Upper extremities	25%	Mortality 2
	Lower extremities	30%	

For purposes of the sanitary service for estimating the character and the amount of material and transportation needed and the time necessary to police the battlefield, battle casualties may be classified as follows:

Twenty per cent. killed.

Eight per cent. non-transportable—serious head and abdominal wounds.

Thirty-two per cent. requiring transportation—20 per cent. sitting up, 12 per cent. recumbent.

Forty per cent. slightly wounded—28 per cent. able to walk to dressing station and field hospital, 12 per cent. able to walk to advance base.

A word in general may be said as to treatment of gunshot injuries:

On the battlefield treatment should be directed to the relief of shock, arrest of hemorrhage, and the prevention of infection.

The treatment of shock is directed to the restoration of the reduced blood pressure by placing the patient at rest in a recumbent position; arresting hemorrhage by tourniquet and bandage; conservation of body warmth; stimulation of the heart; relief of thirst and pain, and application of proper dressing to injury after reducing dislocation and fracture.

Arrest of hemorrhage is effected by compression with hands, application of tourniquet, compress, and firm bandaging and ligation of large vessels.

The prevention of infection is accomplished by avoiding touching the wound with the hands and anything unclean, avoiding any attempt to wash the wound or cleanse it by any other means than the forceps and piece of sterile gauze; the application in and around the wound of the tincture of iodine or an alcoholic solution of bichloride of mercury 1-500; the application of a simple sterile occlusive dressing and of appropriate means of immobilization in the normal position. In the case of penetrating wounds of the abdomen, no food or drink by mouth should be allowed for 72 hours and the patient should be subjected to as little disturbance by transportation as is compatible with securing the necessary shelter.

At the hospital the patient should be thoroughly examined, cleansed, and bodily needs supplied and such measures adopted as are indicated, such as redressing, disinfection and drainage, removal of foreign bodies and loose fragments of bone, excision, amputation, laparotomies, appropriate treatment for aneurysm, hemorrhage, etc. When not imperatively urgent all major operations should be reserved for the base hospitals.

Later in the chronic stages of gunshot injuries it often becomes necessary to operate after use of the *x*-ray for the removal of foreign bodies, necrosed bone, correction of deformities and the restoration of loss of function. Plastic operations are often needed after extensive injuries.

As to penetrating gunshot wounds of the abdomen, a few words may not be amiss in regard to operating. The explosive effects of the pointed small caliber bullet are greatest within a range of 400 yards, but such effects have been noted up to 900 yards. Within this distance there is usually nothing in the external appearance of the wounds to indicate whether the intestines are simply perforated or lacerated and torn by the explosive force. In some cases the discharge of fecal matter and urine may occur, in which there can be no doubt that serious damage has been done. The extent of the injury, however, is usually in proportion to the degree of shock, which is apparent. The symptoms of continuous and serious hemorrhage, when present, will also be apparent. From these latter signs we could say that we have a case demanding immediate laparotomy, provided, of course, we have the facilities at hand to relieve the shock present. Some men might be able to survive from the additional shock from the operation without restorative treatment, but certainly the vast majority would succumb.

If we can restore the patient to a condition which would admit of operating, we would then have to decide whether the surrounding conditions and the facilities for doing a laparotomy are sufficiently favorable and adequate to give a reasonable assurance of obtaining a satisfactory result.

No one who has ever experienced the inevitable lack of means, the usual unfavorable surroundings, the disturbed condition of affairs, and the overwhelming amount of work during and after an extensive engagement would think for a moment that laparotomies with suture of viscera could or should be attempted at regimental aid stations or dressing stations. At the latter stations the most that can be done in an operaive way for such desperate cases will be the establishment of proper drainage, when circumstances permit. When such a procedure is impossible these cases can best be treated at these stations by keeping them at rest, relieving shock and pain and preventing any liquid or food being taken by the mouth. The Fowler position is the best in which to keep the patient. We can rest assured that if the explosive effects have taken place in the viscera any possible operation to close such injury by suture would be futile, hence we have acted wisely by not attempting such.

In a large number of cases of simple perforation of the intestine we know that by adhesion to neighboring viscera or omentum the perforation will be closed in a few hours, if the patient is kept at rest, the bowels kept quiet by morphine hypodermically, and no food and drink is taken by mouth. Hence, under the circumstances, an operation is not as wise as keeping the patient strictly at rest and preventing the taking of food and drink by the mouth, and applying an occlusive dressing after disinfecting the wound with tincture of iodine.

In the cases of increasing internal hemorrhage, when circumstances permit, laparotomy, hemostasis and drainage are indicated, but the surrounding conditions at these stations usually render laparotomy too dangerous and would take away any chances the patient may have of surviving his injury. To subject cases in any of the previously mentioned categories to transportation by any method would but add another danger and largely take away any chance they may have for recovery.

If these cases are retained at the regimental or dressing stations as long as possible the best will have been done for them.

Let us consider these cases after they reach the field hospital.

In the cases in which explosive effects have taken place, operation further than that mentioned is futile.

In the cases of simple penetration, adhesions have closed the wounds in the viscera and immediate operation is no longer indicated.

In the cases of increasing abdominal hemorrhage, laparotomy should be performed, if the surroundings and facilities permit of such being performed.

The prognosis for perforating gunshot wounds of the abdomen depends largely upon the possibility of complete rest and abstaining from food during the first five days. If transportation is obligatory during this time stretcher transport is better than ambulance.

Abdominal wounds by shrapnel bullets are always graver than by the undeformed, small rifle bullet, owing to their large diameter, lower velocity, and usually deformed condition, all causing greater contusion and bruising effect, extensive perforations, prolapse of intestinal mucous membrane and discharge of contents. The shock is very great and closure of perforation by adhesion very unlikely.

Shrapnel wounds of vessels, liver, spleen, and kidneys are usually fatal.

Tangential wounds of viscera by spent rifle or shrapnel bullets usually result in adhesion, inflammation, and later abscess formation, which with proper surgical treatment usually recover. Owing to the large size, low velocity, and usually deformed condition, shrapnel usually carry in pieces of clothing and, therefore, infection; hence surgical interference is always indicated, when conditions are suitable for operating.

In the case of abdominal wounds by deflected bullets, fragments of shells, and bayonets, the operation should proceed by careful dissection of layer by layer, in order that the abdomen may not be opened unnecessarily. Whenever the operation of laparotomy is performed and septic conditions are found the free use of tincture of iodine diluted with equal parts of grain alcohol, as a disinfectant, is strongly advised. All such cases should be drained with a large split rubber tube in which there is a wick of iodoform gauze. Laceration of liver, spleen, or kidneys should be closed by catgut sutures. Gauze packing should be used freely when indicated, and the use of iodoform gauze wrung out in sterile, anhydrous, neutral petroleum is recommended. The patient should be kept in the Fowler position and the continuous instillation per rectum of warm normal salt solution or sterile water, by the drop method, be given until the patient's temperature remains normal and the drainage is removed. No food or fluid should be given by the mouth during the first three days following the operation.

INFANT FEEDING WITH TOP-MILK.*

By J. MILTON MABBOTT, M.D.,

NEW YORK,

CONSULTING OBSTETRICIAN, NEW YORK NURSERY AND CHILD'S HOSPITAL.

In the discussion of a paper on infant feeding read before a medical society in June of the present year, the writer heard a specialist connected with a post-graduate teaching institution in this city remark that he never used top-milk; he had never understood it. He used so much milk, so much cream, so much water, or other diluent, etc.

Now, apart from the mere matter of convenience, which in itself is no small item, there are two very good reasons for using top-milk instead of "milk and cream." In the first place cream is very expensive, and secondly, in New York City, cream is at least a day older than the regular supply of bottled milk. These reasons must be my excuse for endeavoring to demonstrate that it is very easy to understand the practical part of infant feeding with top-milk. The top five ounces of milk in a quart bottle as delivered in New York City in the morning, after standing two or three hours longer, contain approximately from 12 to 16 per cent. of fat. In other words, this quantity of cream and milk, carefully removed from a quart bottle by means of a spoon and dipper, is practically the same as 12 to 16 per cent. gravity cream. If we keep going deeper into the bottle we are getting more and more of the skimmed milk. But, nevertheless, when we take out one pint of top-milk from a quart bottle we are still getting a milk containing from 6 to 8 per cent. of fat, and top-milk, therefore, will enable us to secure approximately the desired percentages of fat, when properly diluted.

*Read at the meeting of the Hospital Graduates' Club, November 19, 1914.

I assume that all those for whom this paper is intended understand the reasons for diluting cow's milk when used in infant feeding, chiefly on account of the excess of casein as compared with human milk; and I shall assume further that you recognize the necessity of adding some variety of sugar, common salt, and possibly other inorganic salts, or lime water, in proportion to the quantity and character of the diluent, whether it be water, a cereal gruel, or a prepared food. Fairchild's peptogenic milk powder, according to the published analyses of Prof. Chittenden of Yale University, and as proven in the experience of the writer, serves a very useful purpose in "humanizing" cow's milk and may be used alone to supply the deficiencies in "top-milk mixtures" as recommended in the accompanying table. Otherwise, suitable quantities of sugar, salt, and lime-water are essential and may be used as indicated in my paper on the "Theory and Practice of Infant Feeding," published in the *New York Medical Journal*, April 18, 1891. That paper covered, I think, most of the apparently glaring omissions of the present one while this, on the other hand, will serve to bring my published suggestions up to date. Unless we use raw milk we must bear in mind the tendency to rickets and scurvy. The latter may be specifically overcome, however, by giving the child a little orange juice two or three times a week.

For the whole milk required at first an extra pint bottle, instead of a quart, may be obtained daily from the dealer, if economy is to be considered; and, of course, there is a pint or more of skim-milk from the quart bottle which goes to waste, or other use, after removal of the top-milk.

Now, observe how simple the whole problem really is. Starting at the age of one week with five ounces of top-milk and ten ounces of water, we increase the amount of food once a week by adding an extra ounce of top-milk and an extra ounce of water to the daily quantity. At the sixth week we have reached ten ounces and fifteen ounces, respectively, and when the baby is seven weeks old our daily quantity has reached eleven ounces of top-milk and just a pint of water. The sixteen ounces of water, or other diluent, should be understood as including the lime-water used, if any. *After the seventh week the quantity of water remains stationary.* We continue increasing the quantity and strength of the food by going deeper into the bottle each week for en extra ounce of milk. At twelve weeks (or about 3 months) we are taking exactly one pint of top-milk out of the quart bottle. *From now on the quantity of top-milk remains stationary;* and hereafter, until the baby reaches the age of twenty weeks (4½ months), the food allowance is simply increased *once a week* by adding one ounce of *whole* milk to the present daily quantity. In fact approximately the same increase of whole milk is the only change for a much longer period. But, as the chart shows, I generally increase the whole milk a little more rapidly, reaching the total quantity of three pints at the age of six months, representing an increase of eight ounces instead of six ounces in the last six weeks.

Beyond the age of six months I do not care to progress on the present occasion, except to state that for the next few weeks the quantity of food remains the same, the whole milk being increased and the water *reduced* in equal amounts. Thus at seven

CHART FOR TOP-MILK MIXTURES (MABBOTT)

		2/3+1/3						

*The whole quantity is prepared at once and divided into the number of bottles indicated.

†We go down into a quart bottle for the quantity of top-milk required each day until we require more than one pint of milk: after that we continue using one pint of top-milk from a quart bottle and a sufficient quantity of whole milk from another bottle, the latter to be well shaken before using.

and a half months the food will consist of one pint of top-milk, a pint and a half of whole milk and half a pint of water; and when we begin to reduce the quantity of water we naturally reduce proportionately the peptogenic powder, or the sugar, salt, etc., which we have added to get the requisite composition. Eventually the top-milk also is replaced by whole milk.

I desire to report the case of a baby, now under my care, which I saw first on Friday, September 11, 1914. The child had been nursed only a few days and artificial feeding had been so unsuccessful that the child, then three months old, weighed only eight and one-half pounds, which was one-half pound less than at birth. On Monday, October 19, the baby weighed eleven and one-half pounds, a gain of three pounds in less than six weeks.* I give the mother or nurse, on each occasion, written directions similar to a prescription for the whole quantity to be prepared at one time and divided into so many bottles.

I must add one more word. Of course we consider a baby's size, weight and digestion, as well as its age. The quantities and proportions are not invariable. Many babies require less than the quantities given. They leave a part of each bottle. Few require more. For such, as a rule, we simply employ a more advanced formula. The weight chart is a constant guide. And the better we comprehend the whole subject of child hygiene and its relations to each individual baby, the better should be our results.

19 Fifth Avenue.

*Note, November 18, 1914: Present weight, 13½ lbs.

THE READINGS OF THE SPHYGMOMANOMETER FROM A CLINICAL STANDPOINT.

By Egbert Guernsey Rankin, M.A., M.D.,

New York.

Professor of Practice, New York Homeopathic Medical College and Flower Hospital; Attending Physician to the Metropolitan Hospital Department of Public Charities and to the Flower Hospital, New York; Consulting Physician to the New York State Hospital for Crippled and Deformed Children.

Discussion of the causal factors of blood pressure and the standard of the normal is not the intent of this effort, but rather the presentation of a personal experience in the use of the sphygmomanometer at the bedside, and deductions as to its practical value in diagnosis and treatment.

As blood pressure within the limits of what is generally called the normal standard may occur in association with recognized pathological changes, and likewise beyond the normal, without apparent abnormalities, the readings of the sphygmomanometer at first glance are sometimes confusing. The interpretation of blood pressure readings is in fact often a complex matter. There is too much of a tendency to estimate its significance by a set standard. Thus a recent writer says without qualification: "A blood pressure exceeding 150 in any subject indicates liability to apoplexy, and unless this condition is treated properly the subject is sure to go on to some serious physical complication, such as dangerous hemorrhages, thrombosis, embolism, or apoplexy." I not only dissent from this statement, but I regard it as dangerous and misleading—at least in our present stage of knowledge.

*Read at the meeting of the American Institute of Homeopathy, Atlantic City, June 17, 1914.

It should be borne in mind that blood pressure is not subject to the laws of physics alone; apparently subject to the same, it is only truly so up to a certain point, that point being the vasomotor system. A given temperature record conveys to the observer at once a certain definite idea, even in the absence of any accompanying data; but in the instance of a blood pressure record, its significance is unappreciable without considerable additional detail.

The taking of blood pressure has been, for some time past, part of the daily routine of the writer—mostly in cardiac, nephritic, and a few cerebral cases. Examples of apparent contradictions are as follows: A systolic pressure of 180 in one case which appeared to be a condition of cerebral embolism, with comparatively mild symptoms; while the same pressure in another is unattended with any symptoms whatsoever. A case of arteriosclerosis with decided hypertrophy, dyspnea on exertion, and some edema of the ankles, with a systolic pressure of 200 and a diastolic of 120, aggravated by the administration of sodium nitrate in 2-grain doses thrice daily—a case which certainly apparently called for a vasomotor dilator.

When interpreting the readings of a given blood-pressure record, taking into consideration the diastolic pressure as well as the systolic, together with the pulse pressure, apart from the great primal causal factor and obviously pathological conditions, there are two other factors which are clinically of equal importance, namely, age and the individual characteristics or features of each case. The first is generally well recognized, but perhaps not sufficiently emphasized. A systolic pressure, for instance, of 120, which suits a person of 25, in one of 55 points to myocardial weakness; in fact, pressures below 120 in persons of that age should be regarded as suggesting pathological changes. Most of the cases observed by the writer of persons over 50 with low blood pressure—that is, below 120—have had decided subjective symptoms when such pressures were persistent. Temporary low blood pressure may exist from general lowering of the system from any debilitating cause.

Cases of myocardial degeneration may be conveniently divided into two types—namely, those of hypertension and those of hypotension—the former, more frequently associated with evidences of arteriosclerosis and cardiac fibrosis; the latter, more frequently with fatty degeneration of the heart, and in the latter stages of cardiac degeneration due to arteriosclerosis. While it must be acknowledged that it is not always possible to diagnose the exact form of degenerative change—especially as fatty and fibrous changes of the heart walls may be and often are associated—the knowledge of the blood pressure in such cases is obviously of great practical value. A systolic pressure of 120 and one of 200 or more in persons of middle life, with decided subjective symptoms, it is a platitude to state, require different methods of treatment; and with all due respect to the most skillfully trained finger tips, this differentiation can be obtained with any degree of accuracy only by means of a sphygmanometer.

Permit me to cite a few illustrative cases:

Case I.—A case of cerebral embolism in a lady of 80, presents these features: The patient for some time past had had a systolic pressure of 190, but had not been under the care of the writer for nearly a year. One morning she fell to the floor unconscious. She was immediately placed in bed and was seen by the writer

in half an hour. She was scarcely semi-conscious, but could swallow; no paralysis apparent; pupils, negative. The systolic pressure was 240; diastolic, 135. There had previously been glycosuria at times, and a trace of albumin in the urine. The presence of the high pressure, in the opinion of the writer, enabled the diagnosis of embolism to be made more readily, likewise exclusion of cerebral hemorrhage. The radials were soft and entirely free from any arteriosclerotic changes, but the pulse was somewhat hard and tense. The patient regained consciousness in about six hours, and ultimately recovered, although at times her mind showed evidence of weakness. The blood pressure has continued from 198 systolic and 130 diastolic to 168 systolic and 110 diastolic. Erythrol tetranitrate has been continuously administered to the patient for the past three months, the dose being increased and diminished according to indications. Potassium iodide was not tolerated.

Case II.—A lady of 80 had had for several weeks previous to the writer's visit what was apparently a mild cerebral embolic attack, followed by slight hemiplegia, confined to the left lower extremity. There was an excessive degree of cardiac hypertrophy with mitral insufficiency and accentuation of the aortic second sound; radials hardened; pulse 90; systolic pressure 240; diastolic pressure 135; dyspnea on moving; no edema; urine negative except for slight trace of albumin; mentality good, other than apprehension in regard to condition. Improvement followed the administration of sodium nitrite in 1½ grain doses three times daily. The systolic pressure fell to 185-195, with a corresponding fall in the diastolic pressure.

In such cases as these the utility of the readings of the sphygmanometer is obvious, and it is a matter of practical importance that the blood pressure should be taken at intervals and any increase noted, with a view to the administration of remedial measures, one of the most important of which is the free clearing of the alimentary canal by catharsis and high enemata, as autointoxication will be found associated with many of these cases.

Case III.—Last January a gentleman of 75 years of age fell to the floor and was unable to rise. The writer saw him about twenty minutes later. The patient was fully conscious; pupils negative; mind very slightly dazed, but a few days later became decidedly more so for parts of a day at different intervals. There was slight loss of power on the left side, although motion was not lost. The pulse was 90, temperature 100°. Systolic pressure 180; diastolic 110. Urine, negative. Bronchial pneumonia developed during the course of the next two weeks; temperature 102.5 -103°; prune juice expectoration and involvement of the lower portion of the left lung. The systolic pressure now ranged from 125 to 130, and the diastolic from 80 to 85. On one occasion the systolic pressure rose somewhat suddenly to 160, and the diastolic to 110, with temperature of 100° and pulse 90; there followed another attack of cerebral disturbance. The patient was dazed and did not know where he was. There was no paralysis; pupils negative.

The fact that the cerebral symptoms in this case were accompanied by a rise of the systolic pressure to such a comparatively low point as 160—together with the 180 systolic register in the attack first mentioned, would seem to suggest that the cerebral vessels could not bear a greater amount of pressure. There was no hardening of the radials, but there was marked loss of memory and mental weakness—in fact, the premonitory symptoms of cerebral softening.

Another case which illustrates the necessity of individualization is as follows:

Case IV.—A man of 49, but with the appearance of a much greater age; specific history; heart markedly hypertrophied and arrhythmic; radials hardened and tortuous; kidneys negative; decided but not excessive edema of the ankles; dyspnea on exertion, with some precordial distress. Systolic pressure 200; diastolic pressure 120. It was certainly natural to attempt, in a case of this nature, to lower the blood pressure, and accordingly sodium nitrite, in 2 grain doses, was administered three times a day, with the result of augmenting the patient's discomfort. Digitalis infusion, 1 dram with 1 drop of a 1 per cent. solution of nitroglycerin, was substituted, with pleasing results. A fortnight later the patient said he was very much better, and perfectly comfortable, although the systolic pressure was 198, practically the same as before.

This case of marked arteriosclerosis appears to be one demanding a high blood pressure, which it would have been very inadvisable to lower. The high blood pressure may be dangerous from other standpoints, but it is evident that the heart called for it. One would perhaps have thought that with such objective symptoms the heart was not any too strong and needed relief. It should be remembered that the heart calls for a certain amount of pressure against which to pump. Lessen that pressure too much or too rapidly, the danger is apparent. While it cannot be said that the heart in this case is strong, it is evident that a high pressure was necessary in order for it to maintain the equilibrium of the circulation. The writer has observed this condition before and regards it as teaching that the lowering of a long-maintained high systolic pressure should be attended with caution.

The writer has observed conditions similar to this in other instances, which, however, must be regarded as exceptional.

It is also inadvisable, and sometimes dangerous, to lower suddenly by vasomotor dilators a temporary high blood pressure depending upon functional disturbances. This is illustrated by the following:

Case V.—Three years ago a physician, 55 years of age, in active practice, in good physical condition; heart and kidneys negative; radials soft; previous blood pressure 160 systolic; discovered one morning that his blood pressure was 180 systolic; as he expressed himself, he was feeling "very fit" that morning, excepting for the high blood pressure. There were no subjective symptoms whatever, although there was a decided lithemic tendency. He took, for the first time, a treatment of high frequency, 750 milliamperes for twenty minutes, after which the systolic fell to 150; the diastolic was not taken then. On returning home the sense of prostration and fatigue was so excessive that he was obliged to keep in a reclining posture until late in the afternoon. Subsequent applications of the high frequency were not attended with such fatigue. The treatment was continued for about three weeks and the systolic pressure was brought down at each application, returning to 160 systolic.

A few weeks ago, another physician in active practice, aged 56, told me very solemnly that his systolic pressure was 200 (I am quite sure he had interstitial nephritis in his mind, although he denied worrying about the condition very much). A few days ago he came to consult me. I took the blood pressure and found the systolic to be 158 and the diastolic 105—just what, in my opinion, it ought to be for a man of his years.

Case VI.—A woman of 55, with a mild interstitial nephritis of many years' standing, complains of shortness of breath on exertion. Her general appearance is that of good health. No cardiac murmur appreciable; accentuation of second aortic sounds; systole, feeble; systolic pressure 120, diastolic 98. Hypertrophy difficult to recognize on account of thickness of chest walls; pulse soft and weak; four days after the first observation a blood pressure of 100 systolic and 75 diastolic. Without a blood-pressure instrument, it is the opinion of the writer that it would have been impossible in a case of this nature to have told whether the systolic pressure was 100 or 130 or more. The diagnosis in this case—in addition to the nephritis—is myocardial degeneration, the low systolic pressure be-

ing regarded as strongly corroborative. Obviously, again, the line of treatment was greatly assisted by the knowledge of the blood pressure.

It would not be difficult to continue citing cases of this nature, wherein the information obtained from the readings of the sphymomanometer was a very positive factor in both the diagnosis and treatment, but let these suffice.

There are, on the other hand, conditions in which the blood pressure readings are not so readily interpreted, and sometimes they are apparently contradictory. For example:

Case VII.—A man of forty-six with mitral insufficiency, hypertrophy, apex half an inch to the left of normal, both second sounds accentuated, compensation perfect; history of an alcoholic neuritis of the lower limbs with some atrophy; said that for years it had been his habit to take about twenty-five generous drinks of whiskey and about fifty cigarettes daily. There were no subjective symptoms. Urine showed a trace of albumin. The systolic pressure was 135 and diastolic 110.

It is safe to assume that as this man appeared strong and in good health except for his alcoholic physiognomy, one should expect a high blood pressure, and it is almost certain that if such had been present the habits of the patient would have been regarded as the cause. Question: Was the patient's blood pressure higher at some previous time? That is not known, as the blood pressure records go back only two years from the time of writing.

Case VIII.—A woman of 80—possibly more—has attacks of fainting, with sensation of impending death; some substernal oppression; pulse full and bounding, sometimes as low as 48, sometimes as high as 68, occasionally intermittent; complains at times of numbness and coldness of extremities; heart sounds somewhat muffled, but no murmur discernible; aortic second sound accentuated; systolic pressure has been for the last three years about 140; the last reading was 158 systolic and 105 diastolic. This patient depends very largely upon the use of cardiac remedies in small doses—namely, strophanthus, nitroglycerin, and strychnine.

Observe the so-called normal blood pressure, with decided subjective symptoms, which undoubtedly depend upon arteriosclerosis and myocardial degeneration. Compare this case with those previously mentioned, of the same age, with systolic pressures of 240 and with very decided evidences of arteriosclerosis, one having also myocardial changes. I think that an explanation is a little difficult; probably a greater degree of cardiac hypertrophy may have something to do with the higher blood pressure.

Case IX.—A woman of 69 has had feebly maintained compensation with mitral insufficiency and an exeessive degree of hypertrophy for many years. In the latter part of last March edema of the lower extremities began to appear, owing to failure of the tricuspid valve. Parenchymatous nephritis also developed. The kidneys, however, had shown for some time past more secondary involvement. The blood pressure at this time was 142 to 145 systolic and 105 to 108 diastolic, being about the same as it had been for two years previous. Observe the failure of the tricuspid valve and the kidney complication, in comparison with the blood pressure. At the time of writing, namely, May 21, 1914, the systolic pressure had fallen to 117 systolic, 95 diastolic, with excessive increase of the edema, which now involved the abdominal walls, and increase of dyspnea.

In contrast with this case, a man of 65 with a mild interstitial nephritis of several years standing shows a systolic pressure of 145, and a diastolic of 108, without any subjective circulatory symptoms whatsoever. Thus we have practically the same blood pressure in these two cases, of nearly the same age, but with very different pathological conditions and very different symptoms. This is likewise difficult to explain, and the writer confesses that he is unable to do so satisfactorily, unless the blood pressure in the case of the man be due to a myocardial weakness also, which was suggested by a previous low systolic pressure of 120, at which time the patient complained of shortness of breath on exertion and debility, but the dyspnea disappeared on his regaining his general health.

It is claimed that the differentiation between cerebral hemorrhage and cerebral embolism depends partly on blood pressure—low in the first instance, and high in the second. In the instance of hemorrhage, it is not conceivable that the mere fact of hemorrhage is the cause of a lowered blood pressure. This,however, is explainable as due to shock. It is said that a systolic pressure of over 160 in a pregnant woman is suggestive of nephritic complications. However this may be, the neurotic element, in cases of this nature, should be remembered. The neurotic element, in fact, must always be taken into consideration in blood pressure records. A nervous impression will cause the pressure to rise ten to twenty points. The application of the armature for a minute may also cause a rise of five points.

The writer's conclusions in regard to blood pressure readings, gathered from personal experience, are: (1) To interpret the true signficance of the readings of the sphymomanometer, one must take into consideration the primary factors, viz., the heart, the kidneys, the urine—the latter also apart from organic disease of the kidneys, for example, indicanuria; the condition of the arterial wall, recalling that arteriosclerosis is often present in association with soft radials, and the effects of neuroses. (2) That one reading is not conclusive; that wide variations are frequently observed in persons in apparent health, such cases being dependent upon neuroses and metabolism; that nephritis may be associated with a so-called normal pressure, and transitory high pressures may be observed in vigorous persons in apparent health. Vasomotor dilators should not be employed in such cases, the treatment of which should be confined to the correction of faulty metabolism and autointoxication, and in some instances amelioration of neurotic conditions. (3) High systolic pressures which are persistent must be regarded as evidence of pathological change. Systolic pressures persistently below 120 in persons of middle life in a large proportion of cases must likewise be so considered. (4) It is the opinion of the writer that many statements in regard to blood pressure are of a too positive nature, considering our present knowledge of the subject, also that some are positively incorrect and misleading. Finally, notwithstanding a certain degree of apparent contradiction, the readings of the sphygmomanometer are frequently a positive guide in diagnosis and treatment.

Alcoholic stimulants and tobacco are regarded by many as essential factors in the causation of arteriosclerosis—but are they? In excess, undoubtedly, especially in susceptible individuals. In moderation, not to any great extent. Here, again, one must individualize one's cases. We must bear in mind that total abstainers and non-smokers have

arteriosclerosis. It may perhaps be of interest to observe in this connection that certain of the mummies of Egypt show evidence of arteriosclerosis. The Egyptians, as everyone knows, had no tobacco, tea or coffee; but they did have some very good wine, which the records tell us they often used to excess. They were, says the historian, "too much addicted to the pleasures of the table." In fact, it would seem that the quantity of the food is of as much importance in the causation of arteriosclerosis as the quality.

226 Central Park South.

DELIRIUM GRAVE WITH REPORT OF THREE CASES AND DIFFERENTIAL DIAGNOSIS.

By EMANUEL S. BRODSKY, M.D.,

WESTPORT, CONN.

ASSISTANT SUPERINTENDENT OF THE WESTPORT SANITARIUM, FORMERLY ASSISTANT OF THE STATE PSYCHIATRIC INSTITUTION IN THE CANTON OF LUZERNE, SWITZERLAND.

Delirium grave was recognized as a clinical entity many years ago. In 1845, Bierrede Bostmant described a mental disease whose symptoms and course appeared in the following manner: After a short prodromal stage with headache and gastric disturbances, there suddenly appeared, and generally very violently, a delirium with great disturbance of consciousness, which was at first more of an anxious nature, but afterward became absolutely incoherent with interminable talking. The taking of food was limited; the weight of the body diminished rapidly; the lips were dry; the tongue was coated with fuliginous fur; speech was difficult, jerky, and finally unintelligible; there was a general trembling of the muscles followed by violent motor and raving impulse, and finally there occurred clonic and tonic spasms. At the beginning the pulse was generally accelerated (100-110). The temperature represented a continuous fever, 100°-102°. Toward the exitus letalis the temperature rose to over 105°, and the patient died in wild delirium and general collapse. The duration was from one to three weeks with recovery very rare.

In 1849, Luther V. Bell described this form of the disease in a paper presented at a meeting of the Association of American Asylums. He described it as a new form of disease which resembled some of the advanced stages of mania and fever, and yet was so far different from any described form of disease as to render it probable that it had been overlooked. In 1851, C. H. Nichols addressed a letter to the editor of the *Journal of Insanity* enclosing a short communication from A. V. Williams to himself, in which was given some account of a form of insanity which is denominated typhomania, from the striking typhoid character of the physical symptoms it exhibits. In 1859, Dr. W. H. Rannes in a paper on insane foreigners, mentions this form of disease as frequent among emigrants. He does not give it any definite name, but diagnoses it as a syndrome, intermediate between mania and typhoid fever. Since that time the same syndrome has been reported under the following denominations: Bell's delirium, Bell's mania, acute delirium, typhomania, and delirium grave, and recently Dercum has described it as a specific febrile delirium.

The following are abstracts of three cases treated in the Westport Sanitarium since 1904. It is through the courtesy of the superintendent, Dr. F. D. Ruland, that this material is available for report.

Case I.—F. C. from Westport, Conn., entered the institution on June 7, 1904. American, thirty-seven years of age and had been working hard as principal of schools in the same town. The causes of the disease mentioned by the relatives were overwork and worry. Heredity of nervous or mental diseases was denied. Patient was strictly temperate. Had been complaining of insomnia and headaches for a week before coming to the institution. On the day before entering there was fear, evidently on account of visual hallucinations. Status upon entering: Good physical constitution, tongue coated, temperature 100° F., appetite poor, speech incoherent, thick and garrulous, gait unsteady, thought people mistrusted him, feared he was accused of something he had not done. Pupils reacted to light and accommodation and narrowed. While in the institution patient shouted constantly. There was a peculiar mixture of religious ideas and praying with profanity. He was delirious and violent and was restrained in bed all the time. The whole body was either tense or in constant motion, and he was boring his head into the pillow. Refused all food. Premonition of death. Rapid loss of flesh and strength. Rise in temperature every afternoon until it reached 105°F. On the third or fourth day patient showed periods of lucidity for several hours, during which the disturbance of consciousness almost disappeared. The patient recognized and responded better to his surroundings, and the delirium was considerably reduced. Apparent lucid periods were followed by an exacerbation of the delirium and excitement. Toward the end the pupils were dilated. Died in sopor on June 23, 1904. Albumin was constantly found in his urine.

Case II.—H. S., a physical trainer, from Brooklyn, N. Y., entered the institution on May 29, 1910. Heredity of nervous or mental diseases and alcoholic excess was denied. Patient was a powerful muscular man forty years of age, and had been troubled by business and family matters for a long time before he came to the institution. Complained of headaches and general malaise for two weeks before admission. The patient arrived at the institution in the early morning very much excited, did not want to walk, trying all the time to sit down, was noisy, had had visual hallucinations, and on account of fear was struggling. Albumin in the urine. Transitory short elation alternated with more prolonged depressive phase, laughing and shouting. May 30: Seemed more rational and talked with ease in the morning, but about 4 P.M. became disturbed and was placed in a restraining sheet. Noisy and restless, boring his head into the pillow and grating his teeth. Shouting a mixture of vulgarity and religious ideas, talking of death, fear of being burned and tortured, saying: "Kill me." "Let me die." Great exhaustion. The temperature was irregular, between 100° and 102° F. June 2 the temperature was 106° F. After a rectal injection of saline solution the temperature was reduced to 102° F. Lateral nystagmus. June 5: Temperature subnormal, exhausted but took nourishment well. Died on June 6 in profound sopor.

Case III.—G. D. J., a colored man, 53 years of age, entered the institution about midnight June 20, 1914. No mental or nervous diseases in the family. Was a strong muscular fellow, but had always been nervous and easily excited. On account of his business he had not slept more than two hours a night for several years. Was very energetic and quite prosperous. He often complained of being sick and of having pain in the side and stomach. Several years ago he had "eye trouble," but the consulted physician found nothing wrong with him. Had been worried much by family troubles. Had had no alcoholic excesses. Attended to his business until June 19 (the onset of the active period of the disease) but did not feel well the last week, could not sleep or eat much, and had headache and constipation. On the morning of June 19 he became suddenly excited, running in the streets, expressing ideas of persecution, hallucination, seeing snakes, dogs and rats, and did not eat well or sleep. When admitted at midnight June 20, the patient was in a retarded semiconscious condition, complained of headache, was relevant but rambling in speech, and showed some insight into his condition. He signed the voluntary agreement, June 21. During the rest of the night patient did not sleep and refused food. Showed slight transitory elation alternating with depression, and purposeless, sometimes streotyped movements; he was restless, constantly trying to sit up or lie down. The tongue was coated but not dry, the pulse was 96-100; there was no tremor, the gait was unsteady; the patient soiled and wet the bed. When

he was offered food he called it poison. He manifested verbigeration or the repetition of sentences such as "I have reached the limit of the world." In the night he tried to put his head through the window and cut his forehead. He talked to himself and carphology was present.

June 22. Slept a few hours, delirious, talked to himself, cried, repeating, "Do not torture me," "Give me an easy death, O God." Refused food. Passed water when the urinal was offered. Pulse 102, of high tension. Morning temperature 101.8° F. Blood pressure 210 R.R. Pupils a little narrowed and reaction sluggish. Perspiration. In the afternoon the depressed phase was replaced by a noisy, resistive and excited condition, the patient using profane language and repeating words and sentences. June 23: Temperature in the morning 101° F., pulse 96, high tension. Shouting "I am going to die"; "I am crazy"; "I want to die as a Roman Catholic." Visual hallucinations and fear. Hypersensibility of the skin. The diagnosis was established on account of the acute onset, the extreme excitement, the peculiar psychomotor activity and the mental attitude, accompanied by fever. Solivetty's treatment was established (hypodermic alministration of ergotin Bonjean). June 24: Temperature in the morning 101.2° F.; pulse 80-84, high tension, considerable perspiration; less delirium and responded to some questions. Restless, boring his head into the pillow, pupils of medium size, respiration irregular, spasmodic (a few shallow followed by a few deep respirations). Passed water when the urinal was offered. At times took liquid food. For a few hours quiet and not delirious. Grimacing and complaining of headaches. Blood pressure, 225 R.R. (Ergotin Bonjean 3 grains four times a day.) Evening temperature 100° F. Consciousness clearer with more insight. June 25: Restless during the night, screaming. In the morning quiet and responded to some questions relevantly. Temperature 100° F., pulse 84. Evacuation after an irrigation. Tongue coated but not dry. Took sufficient liquid food. Toward evening again noisy, delirious and shouting. Temperature 100.8° F. Passed much water. Refused food, spitting it out. (Ergotin 3 grains four times a day.) June 26: Shouting during the night, perspiring. Morning temperature 100.8° F., pulse 84, high tension. Disconnected sentences and mixture of words. Evening temperature 100.4° F. Refused food. (Enteroclysm of salt solution.) (Ergotin 3 grains four times a day.) June 27: Sleepless night, resistive. Morning temperature 102° F., pulse 116. Fed by stomach tube. Delirious, muttering, laid with eyes closed; recognized the physician, repeated, "Oh, I am dead"; "Kill me." Expression of fear. Evening temperature 102° F. Disconnected thoughts, responded to surroundings, hyperesthesia. (Ergotin 3 grains four times a day.) June 28: Morning temperature 101° F.; pulse 90, high tension. Refused food (fed by stomach tube). Delirious, talking to himself, carphology, shouting, "I'll cut my throat," calling the attendants "murder," "thief," evidently in response to visual hallucinations. June 29: Same fear, pulse 84, tension not so high, respiration 30 regular. Took food by the mouth. Superficial bed sores and large vesicles or bullæ on the internal surface of the thigh. Temperature morning and evening 100.8° F. Somnolent all day. June 30: Morning temperature 99.2° F. Profound exhaustion, pulse 78, soft, regular. Responded slowly to questions and took food by the mouth. Blood pressure 180 R.R., respiration 24, regular. In the evening singultus, vomiting, laid helpless and motionless, took liquid food when urged. Respiration 30, pulse 90, not well filled. (Hypodermically caffein sodium benzoate, 2 grains.) Evening temperature 100.4° F. Lateral nystagmus. July 1: Morning temperature 99.2° F. Great exhaustion and emaciation, pulse soft. Evening temperature 100° F. Responded slowly to questions. Constipation. No results from cathartics and did not retain any water introduced into the bowels. Passed water involuntarily. Would not swallow food introduced into the mouth. July 2: Morning temperature 100° F. and more delirious. Toward evening rather better; pulse 90, soft; took food by the mouth in small quantities. Perspiration. July 3: Profound sopor. Did not respond to surroundings. Pupils dilated; respiration 60; pulse 100, irregular, slight perspiration. Temperature 100° F. Died at 9 P.M.

Uranalysis in the third case.—June 22: Specific gravity 1025. Reaction acid, high-colored, albumin 3.5 per thousand, a large amount of granular casts, renal epithelium and a few blood cells. June 23: Specific gravity 1020. Light color, albumin 0.5 per thousand. Microscopic picture the same as on June 22. June 24: Specific gravity 1016. Reaction acid, traces of albumin, a large amount of granular casts, renal cells, a few blood cells and a few crystals of triple phosphate. June 25: Traces of albumin. June 30: Specific gravity 1016. Neutral reaction, light colored, traces of albumin, a few granular casts, no epithelial cells, but a large amount of triple phosphate. July 2: Traces of albumin. Microscopic picture the same as on June 30. The microscopic blood picture was normal.

Our three cases occurred within a period of ten years (approximate admissions during this time about 1,000), all happened to be in the summer time between May 29 and June 21; all were males, one colored, thirty-seven, forty-two, and fifty-three years of age, respectively. In all cases worry and mental overstrain were in the previous history. Heredity of nervous or mental diseases could not be established, and alcoholic excesses were emphatically denied. Neuropathic features were established in the personal history of the third case. The striking feaures of the course of the disease were as follows: Prodromi for a week or two with headaches, insomnia and general malaise. The active period of the disease came on suddenly with restlessness, deep disturbance of consciousness, ideas of persecution, fear with terrifying visual hallucinations and sleeplessness. During the early period of the disease the patients showed short transitory elation alternated with the prevailing depressed phase. Peculiar restlessness and struggling on account of the furious deliria, raving, shouting, trying to escape, or throwing themselves against the window, were prominent in the first part of the disease. There was a mixture of religious ideas with profanity. Premonition of death with the fear of being tortured or burned was prominent in all cases when the disease was well developed or toward the end. Toward the end the symptoms of irritation in the subcortical centers, as, for instance, grating of the teeth, grimacing and lateral nystagmus became manifest.

The apparent lucidity, during which the disturbances of consciousness and the delirium almost disappeared and the motor signs of irritation subsided, lasted usually a few hours and occurred when the disease was well developed. These lucid periods were always followed by an exacerbation of the excitement and delirium. The temperature was irregular, 100-102°, reaching in the first two cases 105-106°, and persisting until shortly before death, when it fell rapidly. Rapid exhaustion was marked in all cases. Toward the end of the disease the disturbance of consciousness was replaced by a profound sopor. The pupils reacted upon light and accommodation, were of normal size or a little narrowed constantly during the disease. Toward the end the pupils dilated. In the third case perspiration and high blood pressure were prominent during the active period of the disease. Toward the end the blood pressure was reduced to 180, evidently on account of the great exhaustion. In all our cases albumin was a constant symptom. In the third case I found in the urine the microscopic picture of an acute parenchymatous nephritis. The amount of albumin and the number of granular casts was gradually reduced to traces of albumin and a few casts. Solivetty's treatment, which was established in the third case, did not show any results.

After the course and termination delirium grave presents a certain syndrome, which should be strictly differentiated from the following diseases: Deli-

rium tremens; any other toxic delirium; febrile deliria which occur in typhoid, typhus, pneumonia and erysipelas, malaria, and meningitis; acute uremic delirium or acute exacerbations of chronic uremic condition, and acute mania. The diagnosis is probably often overlooked on account of the resemblance of the excitement and deliria, which occurs in the above diseases. It would be of interest to the general practitioner to have a review of the differential diagnostic points of these diseases.

Alcoholic delirium might, because of its intensity, suggest delirium grave, especially when it is accompanied by fever. The alcoholic history and the tremor of the lips, tongue, and the limbs will be sufficient at the beginning of the disease to distinguish it from delirium grave. When the disease is well developed, on the fifth or sixth day, the rapid and profound exhaustion, the characteristic mental attitude, the hypersensibility or other symptoms of cerebrospinal irritation with boring of the head into the pillow will give enough reason to exclude delirium tremens. In other toxic deliria the temperature is rarely pronounced, the delirium is much less pronounced.

The delirium in acute infectious diseases, as, for instance, in typhoid, typhus, erysipelas, scarlet fever and pneumonia occurs, for the most part, at the height of the disease-process and during the period of subsidence, and can be easily distinguished by the physical signs, the symptoms of invasion, and the course of the disease.

It is not so easy to distinguish the rare form of delirium which occurs in malaria, the so-called intermittent insanity, lasting hours or days with perfect intermission. This delirium is very similar to that in delirium grave and the impulse to suicide or homicide are of the type that we meet in the delirious state of the excitement of epileptics. The presence in the blood of plasmodii and the history of previous malarial paroxysms may exclude delirium grave.

In spontaneous forms of meningitis of the convexity, the peracute beginning, the frequency of initial chills, the early occurrence of sopor, stiffness of neck and less marked remissions will distinguish it from delirium grave; the delirium and restlessness in meningitis are less marked. There occur also convulsions more often than in delirium grave. Local or general palsies occur in meningitis; in delirium grave they have never been reported.

In acute mania it is important to distinguish the following differential points: (1) Appetite and digestion are normal or increased, while both are absent in delirium grave. (2) Mania rarely runs a course of less than two months, does not usually develop by a sudden outbreak and ends with a considerable period of convalescence, melancholia or dementia. Delirium grave lasts from one to three weeks. (3) Mania is not usually fatal and the strength remains throughout the course of the disease, while delirium grave is usually fatal and the strength fails almost from the first. (4) In mania all impressions seem to be exceedingly fleeting and indistinct, and the mental condition is not attended with imperative concepts. In delirium grave the great confusion is not dependent upon flight of ideas, and the early symptoms of motor irritation do not belong merely to the irritation of the cortical areas, but are symptoms of direct irritation and implication of the subcortical centers. (5) The remarkable alteration of lucidity in delirium grave with the profound implication of the organism are not observed in mania. (6) Fever and albuminuria, as a rule, do not occur in mania.

In uremic conditions the delirium may occur either during the acute uremia or during an exacerbation of the chronic uremia. In both conditions of uremia coma may develop at the onset and in these cases there will be no place for pronounced delirium or any excitement. If coma does not develop at once, muttering delirium with restlessness and sometimes suicidal tendencies may resemble those of delirium grave, but the dry skin and the urinous odor of an uremic, the stertorous breathing, the dry tongue will distinguish it from delirium grave, in which these symptoms represent the reverse; the skin is wet from the beginning; the respiration is usually regular; the tongue is moist; and there is no urinous odor. The perspiration in uremic conditions occurs only toward the end. Convulsions may occur in uremic conditions from the beginning of the disease, while in delirium grave this is possible only toward the end. The characteristic lucid periods of delirium grave are not observed in uremic conditions.

CYST OF THE CEREBELLO-PONTINE ANGLE; OPERATION, WITH RELIEF OF SYMPTOMS.*

BY C. L. DANA, M.D.,

AND

CHAS. A. ELSBERG, M.D.,

NEW YORK.

CASE HISTORY BY DR. DANA.

HARRY E., aged thirty-four, married, three children, sewing-machine operator, family history good.

He denies alcoholism and any venereal disease; no history of any serious injuries or serious illnesses before the present one.

Patient states that he has been ill about a year, but severely so for about six months. During this time he has had very bad headaches, worse at night; in the morning he has had attacks of vomiting which were violent. The headaches were frontal, later occipital, and more on the right side. Recently, also he has had attacks of dizziness and forced movements which threw him to the right. These forced movements of late come on nearly every day. He has had a transient diplopia. He has also developed tinnitus in the right ear and some deafness in that ear. He had to give up work three weeks ago and came to my office on October 3.

Examination.—Mental condition rather sluggish; speech normal; his gait is unsteady with a tendency to fall to the right; he cannot stand with the eyes closed and the feet together; he carries his head inclined to the left; the finger-nose test is uncertain and he shows dysmetria; the pointing test is also imperfect. Adiadochokinesis in right arm; some cerebellar catalepsy.

Cranial Nerves.—(1) Olfactory normal; (2) vision defective; R. 20/40; L. 20/30; distinct papilledema of both eyes + 2.50; (3) lateral nystagmus, to the right more than to the left; otherwise ocular movements nor-

*Read at a meeting of the Practitioners' Society, November 6, 1914.

mal; (4) pupils are equal and react to light and sluggishly to convergence; (5) slight anesthesia of the fifth nerve on the right side with loss of the conjunctival reflex; some weakness of the right motor branch; (6) no paralysis of the third, fourth, or sixth nerves; (7) slight weakness of the right seventh; (8) bone deafness complete in the right ear; left normal; (9 and 10) some difficulty in swallowing.

The knee-jerks and ankle-jerks are present; the right greater than the left. Babinski negative on both sides; no plantar reflex at all on the right; abdominal reflexes lost on the right side; positive on the left; cremasteric reflex slight on both sides. There is no cutaneous or deep anesthesia, except as above noted.

He was sent to the Neurological Institute and was under observation there for several days. There he was examined by Dr. Ward A. Holden, who found the condition of the eyes as already noted.

Dr. Deneh made an examination of the ears and found nystagmus present to heat and cold in the right ear, but diminished in amount; with turning-test, erect posture, horizontal nystagmus seventeen seconds rotation to right; horizontal nystagmus seventeen seconds rotation to left. His conclusion was that the right labyrinth was inactive and that there was a neoplasm below the tentorium on the right side involving the auditory nerve.

Urine examination, negative. Blood-count, normal, no leucocytosis. Serum-Wassermann, negative.

Summary.—A man aged thirty-four, previously well, begins to suffer from severe headaches with attacks of violent vomiting. There gradually develop attacks of vertigo and forced movements to the right; tinnitus and deafness in the right ear and unsteadiness of gait with tendency to fall to the right; clumsiness and asynergia of the right hand; progressively diminishing vision; double optic neuritis; nystagmus more to the right than the left; slight paralysis of the right seventh and slight anesthesia of the right fifth; bone deafness in the right ear with evidence of involvement of the auditory nerve.

He was operated on by Dr. Elsberg on October 15. Examination on November 4 shows an improvement in the optic neuritis; improvement in gait and forced movements; absence of headache and vomiting and improvement in the condition of the cranial nerves.

SURGICAL NOTES BY DR. ELSBERG.

On October 17, 1914, the first stage of a suboccipital craniotomy was done, the bone being removed over both cerebellar hemispheres into the foramen magnum and later into both mastoid regions. Recovery from the operation was uneventful.

On October 25, under ether anesthesia, the wound was reopened and the dura widely incised. There was marked bulging of the right cerebellar hemisphere and only moderate bulging of the left. The posterior cistern contained only a small amount of fluid. The cerebellum was dislocated to the left exposing the right cerebello-pontine angle. The facial and auditory nerves were seen entering the internal auditory meatus. They were small and thin, otherwise normal. In the cerebello-pontine angle and bulging outward and backward toward the nerves was a large multilocular cystic mass with thin walls. When the cyst wall was punctured about 50 c.c. of clear yellow fluid escaped. The cyst wall then collapsed. Pressure upon the right cerebellar hemisphere was much diminished so that the hemisphere sank back into the posterior fossa of that side. The wall of the cyst was so thin that its walls could not be extirpated. Nothing abnormal was found in any other part of the posterior fossa. The muscles, fascia, and skin were closed in the usual manner.

Convalescence from the operation was uneventful. The wound healed by primary union and the patient was up and around ten days after the operation. From the time of the operation the improvement of the patient's symptoms were continual. The headache at once disappeared and did not return. Four weeks after the operation the attacks and symptoms were no longer present, the nystagmus was hardly noticeable. The improvement from that time has been continuous and was only interrupted by a collection of cerebrospinal fluid under the skin, which was removed by aspiration.

While the diagnosis of a localized cyst, a collection of fluid due to an old subarachnoid inflammation, was not absolutely certain, it is very probable that we had to deal with a case of the kind described by Oppenheim and Borchardt in 1910 (*Berliner klinische Wochenschrift*). The condition found by these authors was very similar to that observed in our case, and their patients also improved steadily up to complete recovery. The appearance of the cyst was totally unlike the ordinary dilated lateral cistern which is often observed in operations in the cerebello-pontine angle, being much larger, multilocular, and containing fluid of an abnormal color.

A NEW METHOD FOR THE CONTROL OF POST-ANESTHETIC NAUSEA.

By JOSEPH E. LUMBARD, M.D.,

NEW YORK

INSTRUCTOR IN ANESTHESIA, THE UNIVERSITY AND BELLEVUE HOSPITAL MEDICAL COLLEGE; ANESTHETIST TO HARLEM, KNICKERBOCKER AND LYING-IN HOSPITALS.

THE dread of post-anesthetic nausea and vomiting is in all probability secondary only to the fear of the anesthetic itself.

Having been convinced that the prime factor in this nausea and vomiting is the smell of the anesthetic I have, after considerable experimenting, succeeded in controlling the nausea and vomiting by substituting some pleasant odor for the offensive smell. This I have accomplished by the following simple method:

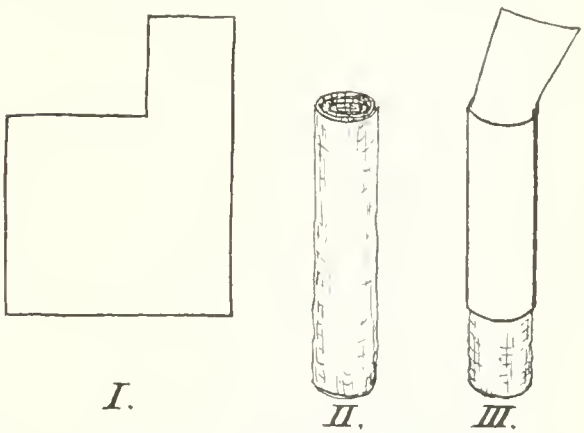

FIG. 1.—Showing the steps in making the gauze cylinder.

A piece of adhesive plaster is cut to the shape shown in Fig. 1, I. Then a piece of gauze is made into a roll of eight or ten thicknesses, about two inches long and one-half inch wide, as shown in II. Now the adhesive plaster is folded over the gauze roll, leaving a small end of plaster free to fasten to the nose, as shown in III. This appliance is fastened to the nose so that the free end of the gauze extends a short distance beyond its tip of the nose (see Fig. 2). On the end projecting beyond the nose is dropped a little perfume. A mustache may be utilized instead of the gauze; but care must be used in dropping the perfume, otherwise it may run into the mouth or nose. This perfume should be applied immediately after the anesthetic is withdrawn, the head being then elevated and turned to one side.

I have tested this method in many cases, where previous anesthesias had produced very troublesome nausea and vomiting, with perfect success.

I do not claim that the method will always produce the desired result; for there are cases which will not yield, in spite of the efforts of the most careful anesthetist. But I do claim that in a large

majority of cases nausea and vomiting will be greatly reduced if not entirely prevented.

In the selection of the perfume is is advisable to consult the patient so as to know which to avoid as well as to know which to select.

Fig. 2.—The gauze cylinder attached.

In my practice I have been led to give preference to the oil of the bitter orange peel. One must be sure of a fresh preparation.

I am well aware that the use of perfume has been recommended before, and with the induction of the anesthetic in order to overcome the offensive odor, but so far as I know no one has made use of perfume *after* the anesthetic, by a similar method, to control nausea and vomiting.

1925 Seventh Avenue.

WHY FUMIGATION FAILS.

By CHARLES F. PABST, M.D.,

BROOKLYN, NEW YORK.

ASSOCIATE DERMATOLOGIST, BROOKLYN HOSPITAL AND DISPENSARY.

In 1895 almost every city in the United States relied on sulphur dioxide for disinfecting purposes. It was known to have no penetrating power, yet health officers used it because nothing better was available. This, therefore, was just the time for "something new" to be introduced, and accordingly, formaldehyde gas was brought to the attention of sanitarians. Being more penetrating than sulphur dioxide, it became popular very quickly, and today it is employed more frequently than any other agent for fumigation.

Let us, for a moment, review the present situation. Formaldehyde, which was introduced at the psychological moment, became the favorite in a short time, and was adopted without the usual careful study. Even now we use a control test for disinfection, which test is not absolutely reliable, and which is the chief cause for the unfounded faith in formaldehyde. This control test is conducted in the following manner: after the room has been properly sealed, a white thread about one or two inches in length and infected with typhoid bacilli or some other favorite organism, is exposed to the action of formaldehyde. This thread remains in the room until fumigation is completed, and is then placed in a sterile envelope and taken to the laboratory for examination. The thread is placed in sterile bouillon and incubated for twenty-four to forty-eight hours. If there is no growth, it is inferred that the room has been properly disinfected. This deduction is not correct, however, and herein lies the fallacy of fumigation. The thread when it is placed in the bouillon contains sufficient formaldehyde to prevent the growth of organisms, and a negative result does not mean that the germs are dead. If instead of placing the entire thread in the culture media, we first cut the thread in half, and place one half in the culture media, and heat the other half for a few hours to drive off the formaldehyde, we frequently find that the tube containing the heated portion of thread shows an active growth of organisms, whereas the result is negative with the thread treated in the usual manner. This means that when the sick-room is aired and heated, the germs which the formaldehyde rendered inactive, again begin to multiply and become a menace.

This fact also explains why some men are getting just as good results without so-called disinfection as with it. As a matter of fact, they are dealing with the same condition in each case. A well known health official shows by statistics that there were as many cases of reinfection after a room was apparently disinfected, as when no attempt was made to disinfect. Getting the same result in both cases, however, does not prove that proper disinfection is useless, but substantiates the assertion that the room was not disinfected in either instance.

It is essential, therefore, that we thoroughly investigate the action of formaldehyde fumigation, and that we hesitate before condemning disinfection itself, because of false beliefs based upon unreliable control tests.

396 Franklin Avenue.

Medicolegal Notes.

Practising without Authority—Sufficiency of Information.—Texas Penal Code, 1911, Art. 750, provides that it shall be unlawful for any one to practise medicine who has not registered in the district clerk's office of the county in which he resides his authority for so practising, together with his age, postoffice address, place of birth, and school of practice to which he professes to belong, subscribed and verified by oath. An information for practising without complying therewith was held to be fatally defective because it failed to allege the defendant's residence and that he had not registered his authority or license in the district clerk's office of the county of his residence, though it alleged that he was not licensed and authorized under the laws of the State to practise medicine, was not practising medicine under the provisions of the laws of the State, and was not a physician under a diploma of a reputable and legal college of medicine.—Young v. State, Texas Criminal Appeals, 167 S. W. 1112.

Hypothetical Questions—Cause of Pain at a Particular Place.—A workman fell into a pit about 18 inches deep on his employer's premises. An expert witness for the plaintiff was asked what in his opinion of the examination of the plaintiff caused the pain at the point of fracture of the tenth rib. This question was allowed over objection by the defendant, and he answered that he thought the pain and tenderness were caused by adhesions below the rib on the inside of the chest bone, and that he had been unable to discover any disease of the spinal cord. He was also asked to what he attributed the pain that was evidenced at the point of fracture. He answered, over objection, that he attributed it either to the old inflammation of the pleura, and to the involvement of the intercostal nerve at that point, or to the bone formation or the adhesions and old scar tissue formed from the pleurisy in the pleura. It was held that the witness was properly permitted to give his opinion, from his examination, as to the cause of pain at a particular place.—Bird vs. Hart-Parr Co., Iowa Supreme Court, 146 N. W. 74.

AN APPEAL FOR BELGIAN PHYSICIANS.

IN a talk before the Green Room Club the other evening, Mr. Irvin Cobb, the well known writer who was a war correspondent with the German Army in Belgium, said that the desolation and misery of the people of that blood-stained and ruined country simply beggared description. "Think of a people," he said, "7,000,000 strong, where everything was gay with laughter at the outbreak of the war. Then picture this people reduced in four months of fighting from 7,000,000 to 3,000,000, and of these 3,000,000 picture 1,000,000 as dependent upon the charity of the United States of America to-night for their supper. Then you have a faint idea of the war and Belgium." A physician of this city was at Maastricht shortly before the fall of Antwerp and was engaged with some Dutch medical men in giving aid to the hordes of refugees fleeing from their ruined homes. In one day he and his companions attended three hundred Belgian women of all classes and degrees who had miscarried as a consequence of the fatigue and exposure of their wretched flight. But words fail in describing the utter desolation of a country in which over eighty once thriving and happy cities, towns, and villages are now masses of blackened and stinking ruins, whose inhabitants have fled to friendly Holland, England, and France. The creature necessities of the other Belgians, those who still perhaps have a roof over their heads but whose days and nights are passed shivering and hungry, are being partially supplied by the charitable of this country and it is hoped that enough may yet be sent them to cover their backs and give them food to carry them through the hard winter or until the end of the war restores to them the opportunity to work for themselves.

But there is a special group of helpless Belgians whose plight must appeal with peculiar emphasis to the medical profession of this country: these are the men whose duty it is and whose joy it would be to minister to the sick among their own people, but who are powerless to do so, having lost not only their personal belongings, and often their houses, but also the tools of their calling. Professor Jacobs of the University of Brussels, in an appeal for the physicians and pharmacists of Belgium, tells of the doctors of that country who have remained at their posts in the devastated localities, some of whom are carrying on their profession in the remains of partly destroyed buildings, while others have to improvise as best they may any kind of shelter for their Samaritan work. "Need I describe," he writes, "the manner in which they sustain themselves, and how they manage to nourish their wives and children? I have witnessed such misery amongst them! Some have had to work as navvies in order to have a few pence in their pockets; others have told me that they had not seen bread for a fortnight, but had lived exclusively on potatoes. Others had a meager bunch of straw laid on the bare ground as a bedstead; the only pair of boots owned by one of them was falling to pieces in tatters. Men I have seen were dressed in torn garments and their children were in rags. One of my colleagues had to live on wayside herbs for three days and three nights, and his wife shared his fate! A professor of a university, bereft of everything, was, when I saw him, in dire want of a bed, and another of equal academic standard was wandering haggard over the countryside, searching in vain for a beloved family. And some of our ranks have been taken as hostages, others have been shot, and their widows and orphans have been left deprived of everything." Of the 4,800 physicians in Belgium before the invasion, at least 1,000 are now absolutely poverty-stricken, and 2,000 more are suffering cruelly. "Consider," says Dr. Jacobs, "the immense suffering that our medical brethren have gone through and are still going through. Their pathetic and lamentable distress should unite all in the desire to relieve it. These practitioners have given a lesson to the world of unfaltering energy, but now their breaking courage will have to be kept up. In this emergency I call on the medical profession to rally to our help. It will be for us a great debt of honor and of eternal gratitude."

This cry from the land of Depage, Thiriar, Bordet, Denys, Van Ermengem, Van Gehuchten, Van Duys, Hertoghe, Laurent, Schiffers, and scores of others known throughout the medical world must appeal to every practitioner, no matter on which side his sympathies are in this fearful war. To systematize the relief measures and to assure those willing to give that their money will be spent to the best advantage, a committee (the composition of which is given in the news columns) has been formed to solicit contributions and to purchase medical supplies, instruments, and surgical dressings for the Belgian physicians, as well as food and clothing for their wives and children, which will be forwarded free of all charges by the Belgian Relief Commission in New York City. We would urge our readers to contribute of their means to this cause, for surely there was never a more worthy one. By giving generously and promptly not only will they be relieving their confrères in thir hour of dire need, but they will also be aiding the sick by restoring to the doctors of Belgium the arms which they need in the combat against disease and which they have lost with their books, their houses, and their savings of years. Contributions may be sent directly to the treasurer of the committee, Dr. Frank F. Simpson, 7048 Jenkins Arcade Building, Pittsburgh, Pa., or to the Belgian Physicians' Relief Fund in care of the editors of any of the following journals: *Journal of the American*

Medical Association, Boston Medical and Surgical Journal, Surgery, Gynecology, and Obstetrics, or the MEDICAL RECORD.

THE NERVOUS SYSTEM AND CUTANEOUS PIGMENTATION.

MORE than ten years ago it was discovered that one of the important sources of the coloring matter of the skin is an end-product of protein disintegration in the intestine, namely tyrosine. In fact, it was shown that all the colors of the butterfly's wing are similarly derived from decomposition products in the bowel. This wizardry of biological chemistry has its counterpart in the production of aniline dyes from coal tar. The pigment cells of the skin are subject to many influences, not only chemical, but also thermic, actinic and mechanical; and are developed to a higher degree of complexity in the lower orders of life, such as the fishes and amphibia. The fact that the latter can in many instances adapt their cutaneous coloration to that of the environment indicates a close relationship between the nervous system and the pigmentary apparatus of the integument. That such a relationship, though less pronounced, exists in human beings is indicated in the instances of changes in skin coloring arising in the course of nervous diseases, and in the conspicuous examples of graying of the hair resulting from fright or intense mental strain.

This subject forms the basis of an interesting study by Fritz Nehl (*Zeitschrift für klinisehe Medizin*, Vol. 81, Nos. 1 and 2). He points out that the instances of so-called sudden graying of the hair as the result of anxiety must be regarded critically. In these cases, according to Landais, there seems to occur, not a disappearance of pigment, but an accumulation of innumerable minute bubbles of air in the hair. The premature graying of the hair associated with prolonged grief and worry is perhaps to be explained on the basis of a disturbance in the general physical condition of the individual. In this instance there are associated with the graying of the hair a general emaciation, a reduction in the hemoglobin-content in the blood, and a loss of tonus in the skin and in the body musculature. There are however instances of the direct effect of changes in the nervous system upon the cutaneous pigmentation. Thus, canities is frequently observed in the territory supplied by a particular nerve. The neural causation is especially manifest if local neuralgic pains are present, as in idiopathic vitiligo, and in the case of the pigmentary atrophic spots of leprosy in which there is a reduction in sensibility in the affected cutaneous areas.

The pigmentary anomalies of segmental pigmented nevi and of congenital segmental albinism are attributed to disturbances in the development of the cutaneous cells rather than to any neurological factor. The question whether the pigmentation of Addison's disease has anything to do with the nervous system has not yet been solved. Undoubtedly, however, the suprarenals with their innervation by the vegetative nervous system have some influence upon the cutaneous pigmentation. That the potent factor is the vegetative nervous system is also indicated in the instances of pigmentation occurring in exophthalmic goiter, diseases of the ovaries, and pellagra, in all of which the autonomic nervous system is involved.

The pigmentation observed in scleroderma and facial hemiatrophy, and frequently confined to the areas of distribution of particular nerves, suggests that the sympathetic fibers in the peripheral nerves are the ones responsible for the pigmentary changes. At any rate, in these conditions there are neither motor nor sensory disturbances. Moreover, it has been shown that sections of sympathetic nerve fibers may give rise to a disappearance of pigment from the skin, as in the cases of unilateral graying of the hair following lesions of the cervical sympathetic, and of heterochromia of the iris occurring after resection of the upper cervical ganglion. It is quite probable, therefore, that prolonged grief and worry may through the agency of the autonomic nervous system give rise to premature graying of the hair.

THE HEART IN DIPHTHERIA.

AN important clinical and pathological study of the irregularities of the heart occurring in certain cases of diphtheria was made by W. E. Hume and S. J. Clegg (*Quarterly Journal of Medicine*, October, 1914). The material comprised 40 cases presenting cardiac irregularities among 573 cases of diphtheria that were admitted to the Hospital for Infectious Diseases of Newcastle-on-Tyne. Of the 40 cases showing irregularities, twenty-two presented the characteristics of a sinus arrhythmia and were associated with normal cardiac signs and symptoms. The remaining eighteen cases manifested many different types of heart irregularity, which are divided into three distinct groups.

In Group I there are included those patients who were very ill from the onset of the disease, in whom there were gross and varying irregularities of cardiac rhythm, with an identical pathological picture. In these patients the membrane was extensive and the toxemia was severe. Prostration was marked, vomiting occurred frequently, and death took place before the fifteenth day of the disease. Dilatation of the heart was obvious before the sixth day and the polygraph revealed a great variety of irregularities. Premature contractions arising in the auricles or ventricles usually preceded a grosser type of arrhythmia. The rhythm of the heart frequently changed from day to day. Autopsy showed a fatty degeneration of the heart muscle, chiefly of the ventricular wall, with patches of interstitial myocarditis, and dilatation and engorgement of the smallest capillaries. In the sinoauricular node there were an increased vascularity and actual hemorrhages. There were no gross histological changes in the dilated capillaries of the auriculoventricular node, nor was there any abnormality in the auriculoventricular bundle or in its two main branches.

The cases belonging to Group II were characterized by the marked toxemia and the extensive septic membrane in the throat. The heart irregularities included auricular and ventricular extra-systoles and a reversal of the normal beat. Pathological

examination of the heart in one of these cases showed a complete absence of the noteworthy feature of the fatal cases of Group I, namely, the increase of fat in the heart muscle cells. The only pathological feature, apart from the increased vascularity, in this case, was the presence of scattered patches of interstitial myocarditis in the ventricular muscle.

Group III included the cases in which there was no evidence of toxemia and in which the throat condition was not severe. Irregularities of the heart were manifest, but there were detected no abnormalities in the heart itself.

In analyzing the results of their study, Hume and Clegg find that it is impossible to correlate the pathological lesions with the individual instances of arrhythmia of the heart. Irritative and destructive processes take place simultaneously and result in excitation or depression of the various functions of the heart muscle. The types of arrhythmia vary from day to day, a result depending upon the varying and progressive pathological changes in the heart muscle and its nerves. The important lesson brought home by the study of this subject is that any form of cardiac arrhythmia (excepting sinus arrhythmia) in diphtheria represents a pathological process in the heart muscle, however mild the illness may otherwise appear to be. The need in these cases of keeping the patient in a recumbent position cannot be too strongly emphasized.

An Experiment in Disinfection

The New York City Health Commissioner, Dr. Goldwater, has ordered the discontinuance of the practice of fumigation as a measure of terminal disinfection following the occurrence of a case of infectious disease. The order will effect all the boroughs except Brooklyn, fumigation being continued in the latter as a control to determine the efficiency or uselessness of the practice. An exception will be made in all the boroughs in the case of smallpox. The sale of fomites as a harborer of pathogenic bacteria has been seriously questioned in recent years by many sanitorians, notably Dr. Doty, former health officer of the Port of New York. Writing in the Medical Record on October 17, 1914, Dr. Doty expressed the opinion that it is entirely justifiable to abandon terminal or room disinfection in the care of diphtheria, measles, and scarlet fever, the destruction of the discharges and constant cleanliness throughout the course of the disease being the proper course. But even if terminal disinfection is called for, the value of fumigation as a means to that end is very doubtful, for, as Dr. Pabst states elsewhere in this issue, the tests relied upon to determine the thoroughness of the measure are fallacious, and that the formaldehyde vapor often fails to kill the germ actually present, although the control test would appear to indicate that it had. The experiment has already been under way in three boroughs since the first of November, and it is noted that so far not a single complaint has reached the department regarding the discontinuance of fumigation, nor has there been any evidence of increased prevalence of infection in the three boroughs where fumigation was discontinued.

The Cause-nexus and Cumulation in Disease-causation.

The belief that diseased states originate in the main through synchronous or contributory operations of individual causal elements must gain ground in the future of pathology; at least in its application to all chronic, insidious maladies. This view may best be illustrated through a case reported by Reich in a meeting of the Tübingen University Clinic at Reserve Hospital II last October (*Münchener medizinische Wochenschrift*, November 3). A soldier sustained a mild frostbite of the first and second toes. He had been in perfect health at the time, and on account of a rainy spell had had to remain in the trenches for 36 hours with his feet under water. The temperature was never anywhere near 0°C. Out of the trenches he had to march 8 kilos. back to quarters, where on account of pains in the feet he was pronounced unfit for marching. During the next five days he complained of insensibility of the great toes and paresthesiæ in the same. The skin of these toes was smooth and shiny. The condition was not attributed directly to actual lowering of temperature beyond a given point, but to circulatory disturbances which resulted secondarily in the continued action of cold or otherwise stated cold and vascular anomalies were jointly produced by different factors. In any case the patient recovered under simple withdrawal of the causes.

The "American Medicine" Relief Committee.

Referring to the call for aid to the Belgian physicians made in another column, we wish to say that to Dr. H. Edwin Lewis, editor of *American Medicine*, is due the honor of having been the first to appeal for the relief of our suffering confrères. This he did over a month ago and in the issue of his journal for November acknowledgment is made of the receipt of a goodly sum. The originators of this new movement were, however, in ignorance of the existence of the *American Medicine* committee, and when they were informed regarding it an organization had already been effected and the cooperation of many prominent men in the profession had been secured. It was decided, therefore, wisely we think, to go ahead with the work, for there is enough to do for both committees and, the aims being identical, there can be no possibility of interference. If any of our readers prefer to give to the other committee we beg them to do so; it matters not through whom relief to our Belgian colleagues comes, so long as it does come.

The Fatigue Toxin and Immunity.

Ranke was the first to show that the aqueous extract of a fatigued frog's muscle when made to perfuse the muscle of another frog evokes in this muscle all the phenomena of fatigue. Weichardt isolated the so-called fatigue-toxin, ponogen, or kinotoxin, and reported later the production of a fatigue antitoxin capable of neutralizing the physical evidences of fatigue. Many investigators have studied the relation between fatigue and disease. In 1909 Scalfati reported that the fatigued organism provides a favorable culture medium for the typhoid bacillus, and one year later De Sandro demonstrated in fatigued animals a diminution in the phagocytic and chemotactic powers of the blood cells.

Vincenzo Palmulli (*Riforma Medica*, October 31, 1914) details the important results of his experiments showing the rôle played by the fatigue toxin in the processes of immunity. He found that in dogs the intravenous injection of this substance causes a reduction in the immune power of their blood serum. The reduction consists in a lowering in the agglutinating, bacteriolytic, phagocytic, and opsonic powers of the blood. It would appear, therefore, as if during fatigue there is an inhibition in the production of agglutinins, opsonins, bacteriolysins, etc. This fact fits in closely with the observations made by Marfan, Jaccaud and others, that physical fatigue predisposes to bacterial infection.

News of the Week.

The Belgian Physicians' Relief Committee.—The committee appointed to solicit contributions for the relief of the Belgian medical men, to which reference is made in the editorial columns, is constituted as follows: Victor C. Vaughan, president of the American Medical Association; William L. Rodman, president-elect of the American Medical Association; J. M. T. Finney, president of the American College of Surgeons; John B. Murphy, president of the Clinical Congress of Surgeons of North America; J. Riddle Goffe, president of the Seventh International Congress of Gynecology and Obstetrics; Charles H. Mayo of Rochester, Minn.; Howard Canning Taylor of New York; Frank F. Simpson of Pittsburgh, treasurer; George H. Simmons, editor of the *Journal of the American Medical Association;* E. W. Taylor, editor of the *Boston Medical and Surgical Journal;* Franklin H. Martin, editor of *Surgery, Gynecology, and Obstetrics;* Thomas L. Stedman, editor of the MEDICAL RECORD. The first meeting of the committee took place in New York on Monday of this week and arrangements were made with the Belgian Relief Commission for free transportation of boxes of medical supplies, food, and clothing purchased by the committee.

Massachusetts Health Council.—Governor Walsh of Massachusetts has appointed the following members of the State Health Council: Prof. George Chandler Whipple, professor of sanitary engineering at Harvard; Dr. Milton J. Rosenau of Harvard, Prof. W. T. Sedgwick of the Massachusetts Institute of Technology, Dr. David Linn Edsall of Milton, Dr. William J. Gallivan of Boston and Dr. Joseph E. Lamoreux of Lowell.

Strike of Hospital Internes.—Twelve members of the house staff of the Kansas City General Hospital recently quit the hospital because the health board had refused to grant a petition by the internes asking for better food and properly heated living quarters. The board denied that any cause for complaint in these respects existed and directed the superintendent to supply the place of any of the house staff who failed to report for duty.

Cholera in Germany and Austria.—Reports from Rotterdam state that thirty-six cases of cholera were reported in Germany by the Berlin Board of Health in November. The same reports say that the disease is spreading rapidly in Austria, especially in Galicia. In the first week of November 844 cases were reported, with 331 deaths in the same period. Ninety of the deaths occurred in Vienna. In the same week 532 cases were reported in Hungary.

Charitable Bequests.—By the will of the late Caroline J. Cammerer, of Philadelphia, the sum of $5,000 is bequeathed "to a worthy hospital in Philadelphia for the endowment of a bed for persons suffering from cancer."

By the will of the late Agnes Nash of Camden, N. J., the sum of $500 is bequeathed to Cooper Hospital.

Journal Consolidation.—The *Dietetic and Hygienic Gazette*, which is just completing the thirtieth year of its existence, has been purchased by The Critic and Guide Company. Beginning with January, 1915, it will be consolidated with the *Critic and Guide*, and the combined journals will be under the editorship of Dr. William J. Robinson.

The Cartwright Prize.—This biennial prize of $500, established by the Alumni Association of the College of Physicians and Surgeons of New York, will be awarded at the Commencement, 1915, for the best essay on a medical, surgical or some kindred subject, provided any of those offered in competition is deemed of sufficient merit. The prize is open to universal competition. The successful competitor must deposit a printed copy of his essay with the manager of the association before securing the money. Essays must be sent to Dr. H. E. Hale, 770 West End Avenue, New York City, on or before April 1, 1915.

Medical Society Elections.—The American Public Health Association, which was in session in Jacksonville, Fla., November 30-December 4, has elected the following officers: *President*, Prof. William T. Sedgwick, of the Massachusetts Institute of Technology; *First Vice-President*, Dr. C. J. Hastings, health officer of Toronto, Canada; *Second Vice-President*, Dr. Juan Guiteras, Havana, Cuba; *Third Vice-President*, Dr. C. E. Terry, health officer, Jacksonville; *Secretary*, Dr. S. M. Gunn, New York; *Treasurer*, Dr. Lee K. Frankel, New York; new members of executive committee, Dr. J. F. Anderson, of the United States Public Health Service; Dr. J. H. Landis, health officer of Cincinnati and Alfredo Dominguez, port officer of Havana. Dr. Eduardo Licéaga of Mexico City was elected an honorary member of the association.

The Eighth District (N. C.) Medical Society, at its semi-annual meeting, held in Winston-Salem on December 2, elected Dr. Joseph W. Ring of Elkin president, and Dr. W. M. Jones of Greensboro secretary.

The Macon, Ga., Medical Society, at its annual meeting on December 1, elected the following officers: *President*, Dr. C. H. Richardson; *Vice-President*, Dr. Harry Moses; *Secretary and Treasurer*, Dr. M. D. Council; *Censor*, Dr. B. S. Gostin; *Delegates to the State Society*, Drs. G. T. Miller and H. M. McHatton; *Alternates*, Drs. W. D. Henford and Heming Winship.

The Muskegon-Oceana (Mich.) Medical Society, at its annual meeting on December 4, elected the following officers: *President*, Dr. F. W. Garber; *Vice-President*, Dr. B. S. Black; *Secretary*, Dr. J. T. Cramer; *Treasurer*, Dr. Lucy Eames; *Delegate to the State Convention*, Dr. F. A. Chapman; *Alternate*, Dr. Frank B. Marshall.

The Lauderdale County (Ala.) Medical Association, at its meeting on December 2, elected the following officers: *President*, Dr. E. B. Hardin; *Vice-President*, Dr. W. B. Turner; *Secretary and Treasurer*, Dr. W. J. Kernachan.

The Buchanan County (Mo.) Medical Society elected the following officers at the annual meeting on December 2: *President*, Dr. J. T. Owens; *First*

Vice-President, Dr. A. R. Timerman; *Second Vice-President*, Dr. W. J. McGill; *Secretary*, Dr. W. F. Goetz; *Treasurer*, Dr J. M. Bell.

The Shamokin (Pa.) Medical Society, at its meeting on December 3, elected the following officers: *President*, Dr. Fred P. Staek; *Vice-President*, Dr. Harry Simmonds; *Secretary*, Dr. L. E. Schock; *Treasurer*, Dr. M. J. Flanagan.

The Oil City (Pa.) Medical Club, at its monthly meeting on December 3, elected the following officers: *President*, Andrew W. Goodwin; *Vice-President*, H. H. Lamb; *Secretary and Treasurer*, S. W. Sellew.

The Dallas County (Ala.) Medical Society, at its meeting on December 3, elected Dr. T. G. Howard president and Dr. G. C. Feulner vice-president.

The Marion (Ohio) Medical Society, at its meeting on December 2, elected the following officers: *President*, Dr. J. W. McMurray; *Vice-President*, Dr S. B. Mattox; *Secretary and Treasurer*, Dr. E. O. Richardson; *Delegate to the State Society*, Dr. A. Rhu.

Personal.—Dr. Thomas H. Fenton has been elected president of the Philadelphia Art Club.

Dr. W. S. Bainbridge of this city, a member of the Reserve Medical Corps, U. S. Navy, delivered a lecture on chronic intestinal stasis at the U. S. Naval Medical School last week.

Dr. George W. Crile, it is announced, is about to sail for France to join the staff of the American Ambulance in Paris to institute the practice of anoci-association in the hospital.

New York City Death Rate.—The deaths reported in this city for the week ending December 5 were 1,385, as compared with 1,372 in the same week last year. If the increase of population is taken into consideration, however, there was a relative decrease in mortality of forty-one deaths, equivalent to a lowering in the death rate of .38 of a point. The death rate for 1914 up to date is 13.44 per thousand, a decrease of .32 of a point as compared with last year's rate. If this decrease is maintained during the three remaining weeks of the year there will be a decrease of 1,786 in the twelve months.

Deaths of Foreign Medical Men.—Dr. Angelo Celli died recently after a long illness. He was born in Cagli, Pesaro, in 1857. In 1886 he was appointed professor of hygiene in the University of Palermo, where he established an antirabic institute, one of the first in Italy. He was later called to Rome as assistant and then full professor of hygiene, succeeding his former instructor, Tommasi-Crudeli. He was widely known through his studies of malaria, which he carried out with Marchiafara and Guamieri; he was the author of several works on "Malaria" and was a founder of the Società degli Studii per la Malaria.

Dr. Charles Perier, a distinguished surgeon of Paris, died on Sunday of this week at the age of 78 years. He was born in Paris and was graduated in medicine from the Paris Faculty in 1864. From 1866 to 1875 he was associate professor of surgery at the University of Paris, and was surgeon to the hospitals from 1872 to 1898. In 1903 he was president of the French Surgical Congress. He was president of the Academy of Medicine of Paris at the time of his death.

Obituary Notes.—Dr. Baldwin Gardiner Cooke of New York, a graduate of the College of Physicians and Surgeons, New York, in 1879, and for many years a medical and sanitary inspector of the New York City Department of Health, died at his home on December 7, aged 59 years.

Dr. James Harper Ramsey of West Bridgewater, Pa., a graduate of the Cleveland, O., University of Medicine and Surgery in 1871, a veteran of the Civil War, and formerly president of the county board of health, died at his home on November 25, aged 80 years.

Dr. William Henry Baldinger of Galveston, Tex., a graduate of the Jefferson Medical College, Philadelphia, in 1885, and a member of the State Medical Association of Texas and the Galveston County Medical Society, died at his home on November 16, aged 55 years.

Dr. William Sherborne Dougherty died at Philadelphia on November 23 at the age of 45 years. He was graduated from the medical department of the University of Pennsylvania in the class of 1894, subsequently becoming resident physician in the German Hospital of Philadelphia. Later he spent two years in post-graduate study abroad and on his return he became Instructor in Physical Diagnosis in the University and Chief of the Medical Clinic at the German Hospital. At a later date he became Assistant Physician to the Methodist Hospital and Physician to the Society for the Prevention of Cruelty to Children. He was a member of the Philadelphia County Medical Society, of the Philadelphia Pediatric Society, of the Pathological Society of Philadelphia, of the Medical Association of the State of Pennsylvania, and a Fellow of the College of Physicians of Philadelphia and of the American Medical Association.

Dr. Charles Henry Reed died at Philadelphia on November 23 at the age of 62 years. He was graduated from the medical department of the University of Pennsylvania in the class of 1878. He was a Fellow of the College of Physicians of Philadelphia.

Dr. William P. Melcher died at Mt. Holly, N. J., on November 30, at the age of 65 years. He was graduated from the medical department of the University of Pennsylvania in the class of 1876. He was a member of the Burlington County Medical Society and of the New Jersey State Medical Society and a Fellow of the American Medical Association.

Dr. James A. Wamsley died at Philadelphia on December 4 as the result of complications following operation for appendicitis. He was graduated from Jefferson Medical College in the class of 1878. He was for twelve years city physician at Gloucester, N. J.

Dr. Frederick W. Koiler died at Philadelphia on November 27 at the age of 44 years. He was graduated from Jefferson Medical College in the class of 1892.

Dr. Albert Charles Peale, geologist and mineralogist, and for more than thirty years connected with the Smithsonian Institution at Washington, D. C., formerly of Philadelphia, died of apoplexy at the German Hospital, Philadelphia, on December 5. He was graduated from the medical department of the University of Pennsylvania in the class of 1870.

Dr. James R. Seymour of Raymond, Ill., a graduate of the Electric Medical College, Cincinnati, O., in 1883, died at his home after a brief illness on November 28, aged 55 years.

Dr. John W. Morgan of Coushatta, La., a graduate of the Medical College of the State of South Carolina, Charleston, in 1857, and for twenty-five years in practice at Minden, La., died at his home

after a short illness on November 29, aged 84 years.

Dr. ADELINE WILKINS WILDES of Boston, Mass., a graduate of the Boston University School of Medicine in 1881, died at her home in Roxbury after a long illness on December 6.

Dr. GEORGE DEXTER BULLOCK of Weymouth, Mass., a graduate of the Jefferson Medical College, Philadelphia, in 1886, and a member of the American Medical Association, the Massachusetts Medical Society, and the Norfolk District Medical Society, died at his home on December 6, aged 55 years.

Dr. JOHN T. HUBEL of Detroit, Mich., a graduate of the Detroit College of Medicine and Surgery in 1899, died at his home from pneumonia after a short illness on November 29, aged 37 years.

Dr. ALBERT ELLIOTT WRIGHT of Ecorse, Mich., died at his home on November 28, aged 70 years.

Dr. DARWIN A. STEWART of Winona, Minn., a graduate of the College of Physicians and Surgeons, New York, in 1869, a member of the Minnesota State Medical Association and the Winona County Medical Society, and formerly mayor of Winona, died in St. Barnabas Hospital, Minneapolis, on December 1, aged 69 years.

Dr. THOMAS J. COLE of Van Wert, O., and formerly of Mansfield, a graduate of the Electric Medical College, Cincinnati, O., in 1875, died at his home from paralysis on November 30, aged 60 years.

Dr. JOHN W. RUTH died at Lancaster, Pa., on December 9 in the sequence of a surgical operation at the age of 32 years. He was graduated from Hahnemann Medical College and Hospital of Philadelphia in the class of 1905, and he served for a year as interne on Blackwell's Island, New York.

Dr. JOHN WIEBLY BEALOR died at Shamokin, Pa., on December 11 at the age of 60 years. He was graduated from Washington University Medical School of Baltimore, Md., in the class of 1876.

Correspondence.

AMERICAN AMBULANCE WORK IN FRANCE.

[We are permitted to publish the following extract from a letter received by a physician of this city from a member of the Whitney flying hospital staff in France.]

DEAR PROFESSOR:

Paris is like a different city from the one we have known before—and it is both sad and gratifying to see the change. On all sides one sees flags flying, French, English, Belgian, and Russian; but the fluttering bunting seems only to accentuate the mournful air of the whole place. One is struck by the numbers of people in mourning and by the absence of the motor busses that used to crowd the streets. Many of the shops have their shutters permanently in position, with the inscription "Fermé jusqu'à la fin de la guerre" or "Fermé à cause de mobilization," and others, if the name on the sign is at all suggestive of a German origin, have large placards stating "Maison Française." All offices and places of business are closed from 12 to 2 owing to the reduction in forces which does not leave enough employees to run the place during the lunch hours. At night the streets are pretty dark, for only a portion of the lights are going and, though the boulevards are not empty, there is nothing like the usual gay crowd to be seen. What is pleasing is that on all sides there is evidence that the people realize they are facing a serious crisis and that the real underlying sobriety and earnestness of character they possess has come to the surface. All of the theaters are closed, the cafés close at 8.30 and the restaurants at 9.30, so that after that hour there are absolutely no gathering places for the people, and everyone goes soberly home. Their idea is that while the soldiers are suffering all manner of hardships at the front it would be wrong for those remaining at home to be indulging in any form of enjoyment. The big hotels are empty, either entirely closed or with only a few rooms open, as is the case here where we doctors are staying, and there is here a flat war rate of 5 francs a day per person in all the rooms. Some of the fashionable places like the Elysée Palace and Claridge's have already been converted into hospitals, and the other big hotels are in readiness to be used for this purpose.

We have found the hospital situation here full of surprises. First of all, the American Ambulance Hospital is on a scale of elaborateness and perfection of equipment which we none of us expected. It is at Neuilly, outside of the gates, in a school building called the Lycée Pasteur which was not quite completed when the war began. It was, therefore, possible to adapt it most advantageously to hospital purposes, and as far as efficiency goes it seems more like a permanent institution than one established in an emergency. There are about 450 beds, though at present there are only about 350 patients, and the equipment is in every way adequate for their care. Dr. Du Bouchet, who is the medical director, seems an excellent executive, and of course, Dr. Blake's work is just as fine as one would expect. The administrative side of the institution is managed by a committee of about ten Americans, most of them prominent business men here, and they do it beautifully. In addition to the trained nurses and orderlies there is a huge crowd of volunteer Red Cross workers, most of them belonging to the leisure class here, both men and women, and many of them not Americans. These are fine in their willingness to work, and they perform the most menial tasks with the greatest cheerfulness. One Russian count who is doing orderly's work has the bullets and fragments of shell removed from the patients mounted in gold and then returned to their owners as souvenirs! The injuries are perfectly frightful, and of course the wounds are always badly infected. There is so much delay before the men reach here that they are generally in an awful state when they arrive. Yet the mortality is not so great as one would expect, about 55 deaths out of the first 700 cases. There is a fair amount of gangrene and gas-bacillus infection, especially in wounds of the lower trunk and lower extremities, due, I suppose, to infection with intestinal bacteria carried into the wounds from the clothing. The kitchen of the hospital is a perfect marvel. It is run by the former manager of the Hotel Frascati at Havre, who is giving his services and who has had most of the pots and pans loaned by the big local hotels. Staff and patients eat the same food, yet it costs only about 1 franc 10 centimes a head daily—and it is excellent! Every body is autopsied, and I have seen some extraordinary cases—bullets in the pericardium, half the face blown off, the whole perineum and inside of the thighs torn away, a man with over a hundred wounds, etc.

Another surprise that we had was when we learned of the plans for our work. When we ar-

rived it was intended to send us at once up into Belgium, and various places were considered for the purpose, but on investigation it was found that these were either already in the possession of the Germans, or else in country that had been so completely devastated as to make it quite out of the question for a hospital to exist. After some time had been lost in this way, Mr. Bacon and some members of the committee went to Bordeaux to see the officials of the War Department, and they gave us as a site the old monastery of Juilly, which is on the road to Soissons, and this, I think, will be a splendid place, for it appears that the Germans are concentrating their attacks there, and refugees from that region are beginning to reach Paris. In the meantime we have been as busy as possible buying equipment, for we have been ordered to make ready for a 200-bed unit, and with business in the present disorganized condition here it means an infinite amount of running around. There is going to be some delay before we can start in, for the place is most primitive and some necessary plumbing and some heating appliances will have to be installed. Martin is perfectly fine, and we are very fortunate to have him as our chief.

Mr. G. W. Carr James Morgan, of Harjes and Company is the chairman of an organization for the distribution of clothing, etc., to the destitute, and would be glad to receive any stockings, mufflers, etc., that are sent to him.

KARL M. VOGEL.

PARIS, November 25, 1914.

Progress of Medical Science.

Boston Medical and Surgical Journal.

December 3, 1914.

1. Medical Problems in Education. The Responsibility of the Medical Profession. T. F. Harrington.
2. The Duty of the State to the Psychopathic Hospital. W. Channing.
3. Progress of the Psychopathic Hospital on the Prophylactic Side of Mental Hygiene. E. E. Southard.
4. The After-Care Program and Results of the Psychopathic Hospital, Boston, 1913-14. A. Warren Stearns.
5. Further Notes on the Economic Side of Psychopathic Social Service. Mary C. Jarrett.
6. High-Grade Defectives at the Psychopathic Hospital During 1913. T. H. Haines.
7. Genetic Factors in 100 Cases of Psychoneurosis. D. Gregg.
8. The Point Scale. A New Method for Measuring Mental Capacity. R. M. Yerkes and J. W. Bridges.

3. The Psychopathic Hospital and Mental Prophylaxis.—E. E. Southard states that mental prophylaxis should include the proper temporary care of persons suffering from mental derangement under the conditions of general hospital and private practice; the stimulation of voluntary admissions to existing and future hospitals for the insane; the establishment of psychopathic hospitals in proper centers, having proper medical and social arrangements for the highest forms of intramural and extramural individual and community service. The author ventures the hope that the term "psychopathic" will be extended to include both the legally insane and the great variety of other mental cases including psychoneurotics, mentally deficients, and criminalistic and possibly other types of mental disorder; and that the term "insane" will be discarded by physicians, except under court conditions. The term "insane" is rightfully considered a legal and not a medical term. One of the greatest features of a mental hygiene propaganda will be to convince the world of this fact.

8. The Point Scale for Measuring Mental Capacity.—R. M. Yerkes and J. W. Bridges have designed the point scale to take the place of the Binet method as a more definite and accurate index of the mental capacity of individuals. The mental capacity is measured in terms of units. A total score of 50 points gained by an individual indicates that he has achieved just one-half of the possible number of credits in the scale. His mental capacity, as compared with other individuals of the same or of different age, of the same or of the other sex, of the same or of another race, of like or of contrasted social status and educational opportunities, may be determined and definitely stated in terms of norms established for use in connection with the point scale. The application of the scale itself to an individual yields merely a certain total of points which is entirely meaningless to the inexperienced examiner, except in the light of norms. In this respect, the authors' point scale differs radically from the Binet measuring scale of intelligence, for the latter is self-contained and complete in itself, demanding no norms nor any other sort of accumulation of information as the basis for its intelligent use, nor indeed for the interpretation of its results.

1. Tonsillotomy versus Tonsillectomy.—T. R. French concludes that differential diagnosis should be made to determine, if possible, whether the tonsils are the probable sources of infection or are free from disease. The indications of the clinical history and outward appearances of the glands are often sufficient for this purpose. Because of the possible existence of a tonsillar function, also because of the subsequent pharyngeal deformity and the consequent alteration of the quality of the voice occasioned by tonsillectomy, it is desirable to leave the capsules in the tonsillar fossæ whenever possible. While all extensively diseased tonsils should be enucleated, it is probably safe to say that at least 80 per cent. of enlarged tonsils do not contain foci of infection and, therefore, do not need to be completely removed, and, indeed, unless obstructive to voice or respiration, do not need to be removed at all. In cases in which there is a doubt of the character of the interior of the tonsils, but which are brought to operation for the removal of irritating or obstructive adenoid growths, a fairly accurate knowledge of the condition of the crypts or of the presence of pus sacs or pockets can be obtained by removing, at the beginning of the operation, a substantial portion of one tonsil and submitting it at once, in a brilliantly illuminated field, to examination under a finely ground loupe with a magnification of from five to ten diameters. If the tonsil from which the section has been taken is found to be apparently free from disease, and the clinical history is without significance, the remainder of the gland should be removed by complete tonsillotomy—that is, down to the capsule. The opposite tonsil, if not obstructive, may then with propriety be left alone, but if obstructive, it also should be removed by complete tonsillotomy. If the exploratory section, however, shows that one tonsil is diseased, then both tonsils should be enucleated. The base left after a considerable part has been removed for examination, can be as readily enucleated as if a part had not been removed.

3. Backache.—C. Ogilvy points out that the exact

cause of backache should be sought for and definitely determined. A thorough examination is too seldom made. The cause is very often found to be a postural deformity with a resulting muscle strain. The cause of the postural deformity is very frequently weak feet. A sacroiliac joint strain, with or without muscle strain, is responsible for a number of cases. When retrodisplacement of the uterus is suspected, a bimanual examination will immediately settle the diagnosis. The diagnosis of muscular rheumatism should seldom be made, as by so doing one is simply evading the question. When myalgia is present, an infectious origin should be sought for. Spinal disease, such as Pott's disease, presents such a different picture, that it should not be confounded with any of the conditions enumerated. The diagnosis of osteoarthritis is made clear by the age of the patient and the history of the case and can in every instance be corroborated by the *x*-ray. More careful attention should be given to all patients complaining of backache to seek for and to remove its cause, not only for the relief of pain complained of, but also to prevent the complication of the undermining of both the general and nervous systems which may directly follow.

6. Tumors of the Testicle.—F. Hinman concludes that orchidectomy will cure from 15 to 20 per cent. of teratoma testis. Obviously a cure is possible only when the testicle is removed before the onset of glandular or other metastases. A cure cannot be assured until nine years after operation, although the danger of recurrence after four years is very small (only three cases reported) and progressively diminishes. Cancer of the testicle metastasizes in practically every case first and primarily to a limited zone of lumbar lymphnodes which lie on the aorta for the left testicle and on the vena cava for the right, between the bifurcation of these vessels and the renal pedicle. Communication between these two groups and to deeper or more distant glands occurs only secondarily. Involvement of these primary lymphnodes may occur early or late, and the preoperative duration of the tumor in the testicle, its rapidity of growth or its size give no definite clinical indication of the onset or extent of such metastases, but the probabilities increase the longer the duration and the more rapid the growth. Pathological differentiation of tumors of the testes into embryonal carcinomas and mixed-cell types is more or less arbitrary as both are teratomatous in origin; but the former appears to be definitely less likely to metastasize, although more rapid in its growth. There are fewer cures among the cases of teratoma, although these give the longest duration before death. The primary lymphnodes are a very imperfect guard against secondary invasion, and metastases to other gland areas by way of efferent lymph-channels or by blood-vessels to thoracic or abdominal organs may occur early. Surgical treatment is of no avail after these secondary metastases have occurred. The only hope, therefore, in a radical operation is the removal of the testicle with its primary lymph area before the disease has spread beyond this zone. The experience of various surgeons in a total of forty-six cases has demonstrated in suitable cases the feasibility and technical ease of the radical operation with a combined surgical mortality in all cases of only 11 per cent. Radical operation should never be undertaken when lumbar metastases are recognizable clinically.

10. Mouth Infection and Systemic Disease.—F. Billings points out that secondary, alveolar focal infection may be the dominant factor in the production of systemic disease, of which malignant endocarditis, chronic arthritis, and myositis are examples. The dominant organisms belong to the streptococcus and pneumococcus group. In addition, the staphylococcic fusiform bacillus, the *Bacillus aerogenes capsulatus* and saprophytic organisms are found. But the streptococcic group are apparently the important ones. In five patients suffering from Hodgkins disease, alveolar abscess culture has revealed the diphtheroid bacillus of that infection. Systemic actinomycosis may arise from alveolar infection, due to the ray fungus. These disorders, due to a focus of infection, are probably always carried by the blood. The infected tissues of experimentally inoculated animals and the infected muscles, joint tissues, lymphnodes, etc., yield special bacteria and histologically there is found embolism of the small and terminal blood vessels. Local hemorrhage and endoarterial proliferation are seen, interstitial growth, cartilaginous, osseous, vegetative and other morbid anatomical changes, according to the character of the tissues infected. Part or complete ischemia of the tissues, due to the embolism, is an important factor, as has been experimentally shown. Tissue and exudates of foci should be carefully examined, vaccines of the bacteria may be made for subsequent use. After the removal of the focus, the body defenses should be improved, which may involve a long and tedious period in some cases. Mental and physical rest, wholesome food, pure air, pleasant surroundings, and, in some cases, restoratives are necessary. Pain must be palliated by simple drugs or salicylates, and after a time passive exercise and graduated active exercise may be added. Autogenous vaccines may be used in some cases, especially in the later stages of chronic arthritis.

3. Heart-block in Acute Rheumatic Carditis. A. E. Naish, A. M. Kennedy.
4. On the Localization of Bullets and Shrapnel. W. Overend.

1. The Patient and the Disease.—Sir Dyce Duckworth notes that apart from morbid symptoms there is a personal factor in every patient. A disease may be well-borne or ill-borne. Family history and inborn tendencies may be important factors. The degree of recuperative power varies much in different families, likewise the measure of inherent vitality. A tendency

to slow repair and a general vulnerability may be readily observed in all persons of a strumous habit of body. In patients of the arthritic type there is a large measure of resisting power with much vitality. The tolerance for certain drugs is found to vary largely in different patients. Apart from pure idiosyncrasies the beneficial effects of mercury in the dark-skinned, bilious, and arthritic subjects, and its less satisfactory action in the fair and strumous ones have been frequently observed.

2. **Myeloid Sarcoma.**—M. J. Stewart concludes that myeloid sarcoma is locally malignant only and does not undergo dissemination. It is to be clearly distinguished, both clinically and pathologically, from malignant giant-cell sarcoma, in which death with visceral dissemination is the rule, even after the most radical operative treatment. The histological diagnosis is based on the morphological characters of the giant cells, especially as regards their nuclei. In myeloid sarcoma the latter are numerous, uniform, small, and without mitoses; in malignant giant-cell sarcoma they are few, sometimes single, irregular, and often very large, while mitotic figures are frequent. After investigating a comparatively large series of cases, and from a study of the literature, the author advances a strong plea for the conservative treatment of myeloid sarcoma; and advocates thorough curettage as the operation of choice in the first instance in suitable cases; failing this, a local resection of the growth. Amputation should be the last resort, and only after the failure of less radical measures. An accurate histological investigation of the tumor is in all cases essential.

1. The War and Typhoid Fever. Sir William Osler.
2. A Report on Gas Gangrene. Sir Anthony A. Bowlby and S. Rowland.
3. Injuries to the Bowel from Shell and Bullet Wounds. P. Lockhart Mummery.
4. Leeches. By A. E. Shipley.

1. **The War and Typhoid Fever.**—Sir William Osler alludes to the fact that typhoid fever is nowhere prevalent in the English camps. He believes that isolated cases should be scrutinized with the utmost care. "Watch the common ailments" should be the motto of the camp surgeons. The following measures are indicated: Every recruit should be asked whether he has had typhoid fever, or if during the previous twelve months he has lived in a house with a case of fever. An affirmative answer should mark the man for laboratory study. There should be a realization of the extremely protean character of typhoid fever, so that mild cases of enteritis, obscure forms of bronchitis and pneumonia, and mild cases of fever should be watched with care. Every typhoid patient should be regarded as a focus of infection, and should be suspect as long as the bacilli are present in the discharges. The cases should not be treated in the general wards with other cases. Measures should be taken in the larger camps and in the garrison towns to segregate the cases. No typhoid patient should receive a clean bill of health until he has been shown by bacteriological examination to be harmless. Ample provision should be made for the careful bacteriological examination of all suspected cases.

2. **Gas Gangrene.**—Sir Anthony A. Bowlby and S. Rowland have made a study of the spreading gangrene which has occurred among the wounded of all the armies now in France. A bacillus has been isolated from a typical case, and the conclusion is reached that this microorganism is probably the specific organism of malignant edema. The gangrene always occurs in connection with wounds of the extremities, and to a greater extent in serious than in slight wounds. The onset is characterized by swelling of the injured part, and the gangrene seems especially liable to occur in connection with that swelling of a limb which is due to extravasation of blood in the subcutaneous tissues and intermuscular planes. Interference with the circulation either by extravasation of blood or by tight bandages has a marked influence. In the early stages the patient complains of severe pain which is perhaps due to tension, the result of the swelling, but in the later stages the affected area becomes completely numbed and insensitive. The edges of the wound are generally ragged and sloughy, and a considerable quantity of blood-stained serum constantly exudes and soaks the dressings. This discharge emits a characteristic and most offensive odor which is so marked as to be almost diagnostic. The skin, if not previously discolored by extravasated blood, assumes a dark purplish or slate-colored hue. In the vicinity of the wound it changes subsequently to a more green color. The swelling extends coincidently with the change of color, and a few hours later the skin becomes nearly black, and finally forms a black, leathery slough. Beyond the area of discoloration the limb is swollen with gas and fluid exudation, and an emphysematous crackling can be elicited on pressure with the hand. This may spread to a distance of as much as a foot above and below the actually gangrenous area, and so rapid is the extension of the gangrene that the authors have seen the whole of the lower extremity completely mortified before the end of the third day after the infliction of the wound.

Congenital Dropsy.—Wienskowitz concludes his serial article on this subject as follows: Congenital dropsy with fetal anemia, as described originally by Schride—a case of which the author describes of the relapsing type—is evidently the result of a toxic influence upon the fetal blood formation, in all probability derived from the mother. The nature of this toxic substance is quite unknown and probably also complex in nature. Whether or not nephritis or pregnancy nephritis plays a rôle here cannot be denied outright, but this is not very probable. The author's case shows that the toxic substance can be associated with severe anemia on the part of the mother. Nevertheless the maternal anemia is not specific for the fetus. The idea that all kinds of noxious influences can bring about anemia and dropsy in the newly born is borne out by interesting old finds. Thus Dareste succeeded in producing anemia and dropsy in a fowl embryo, using the most varied noxæ—high or low temperature, covering the egg with varnish, causing the poles of the egg to turn about, etc. Various malformations were thereby produced but in many cases general anasarea was also present.

The Arrow as a Weapon in Aerial Warfare.—Coenen describes certain arrows or darts dropped by French aviators upon the German troops. Gravity is the only force necessary, the point of the projectile being the heavier end. The dart is about the size and shape of a pointed lead pencil. The lower third is pointed and solid, while the upper two thirds are so constructed that a cross section shows a cross instead of a circle, thereby securing lightness. The velocity of the projectile naturally increases with the distance in accordance with the laws of gravity. The device is ingenious but its value in war is thus far problematical. In the case of troops in bivouac considerable damage could

be done. For an aeroplane to carry them in immense numbers and then discharge them rapidly would interfere with the ballasting of the air craft. On a recent night a number of these missiles were discharged upon a company of pioneers none of whom was injured. Thuds were heard as the arrows struck the earth, with an occasional hissing sound as the air was parted. In the morning 50 of the missiles were picked up. Two thirds stuck in the earth, slightly bent. Should opportunities come forward Professor Coenen will report on the nature of the wounds caused.

Effects of Lumbar Puncture on Extramedullary Tumors.—Newmark of San Francisco begins by citing the statement of Oppenheim that the unfavorable consequences of lumbar puncture are not always published. The occasion of his remark was the fact that puncture in a case of extra medullary tumor was followed by increased compression in the cord and paraplegia. The author cites two cases of the same type. In the first, lumbar puncture relieved the compression of the cord by withdrawing 6 c.c. of spinal fluid. Before puncture the chief pressure symptom was a paretic right lower extremity. Soon after puncture from increase of intramedullary pressure paraplegia set in. After the removal of the tumor—a psammoma—the condition cleared up, so that this patient suffered no permanent disability. In the second case after puncture had caused a similar result a tumor, also a psammoma, was extirpated with great difficulty, the patient ultimately recovering her motility. In these cases of puncture as preliminary to extirpation of tumors there was, of course, no technical blunder, but patients are not always so fortunate, for the increase of pressure may be sufficient to cause absolute paraplegia and in tumors high up in the canal operative intervention may end fatally as in a case of Nonne's.

Berliner klinische Wochenschrift.

November 2, 1914

Eczema and Neurodermitis in Childhood.—Lechnert states that Vidal was the first to separate neurodermitis from the eczemas. He termed the condition chronic circumscribed lichen because clinically it was a lichen and as such had been described by older authorities. It began as circumscribed papules which itched intensely, and which tended to consolidate to form placques. Apparently there was no exogenous causation, and, since it occured in neuropathic subjects and the itching was apparently subjective the affection was later christened circumscribed chronic neurodermitis. Close study revealed special clinical and histological peculiarities, so that henceforth confusion with eczema or any other dermatosis seemed impossible. Its nearest congener appeared to be prurigo from which, however, it should readily be distinguished. Neisser was nevertheless disposed to replace the affection within the eczemas of which it constituted a sharply individualized form. Continued observation showed that it could occur in the mucosæ which were continuous with the skin, as the lips, conjunctivæ, genital mucosæ, also that it sometimes located itself on the palms and soles causing verrucoid lesions. It even appeared as a moniliform dermatosis, like lichen planus—mere strips or single rows of papules. Of late years its presence has often been noted in children, even in scrofulous children. Differential diagnosis is the more difficult because eczema and neurodermitis readily develop in the same child. In the past two years nearly 300 children have been treated at the local clinic (Frankfurt a. M.) for one or the other affection or a possible association of the two. The proportion of eczema to neurodermitis was about 3 to 1. In 12 cases a diagnosis was impossible. In the undoubted cases of neurodermitis a neurotic substratum was by no means always in evidence. On the other hand a scrofulus component was often noticeable. The order of evolution in children agreed with that seen in adults: a primary, subjective itching, very violent and appearing in crises; the characteristic papules which form placques; the increasing resemblance to a lichen; and chronicity. Tarry preparations are much used in treatment.

Diagnostic Significance of Hemoglobin-rich Macrocytes.—Dünner believes that the original difficulty in differentiating between pernicious anemia and the severe secondary types is gradually vanishing, although something depends upon how we group the anemias, and also on the selection of tests. The use of some refinements of diagnosis may only defeat the object in view. The hemoglobin find and blood pictures seem to suffice in the clinic. In secondary anemias we see the evidence of attempts at rapid repair which are much less pronounced in the pernicious form. Paradoxal finds in rare cases seem to point to the possibility that a secondary anemia from acute hemorrhage may itself give rise to pernicious anemia. The socalled hyperchromic macrocyte, for example, generally regarded as peculiar to the pernicious type may sometimes be encountered in secondary forms. This may be merely an accident and without significance, or it may show that the primary and secondary forms have something vital in common. This cell when seen in blood which answers in other respects to secondary anemia cannot obscure the diagnosis.

Belated Reports of Atoxyl Blindness.—According to Makrocki, despite the numerous cases of blinding traced to the use of atoxyl (notably among African negroes treated for sleeping sickness), and the resulting apparent abandonment of the use of the drug under all circumstances it is still being used extensively. One colleague has made over 500 injections without a single untoward effect. During the present year, however, a case was reported in which a very small dose caused a "high degree of amblyopia." This reporter, Steinebach, believed the case to be unique but the author saw one of the same type in 1902 when the drug was being widely used. The patient was an old woman with a lymphoma of the neck and also a history of malaria. She had been taking Fowler's solution without benefit, and now received three intramuscular injections of atoxyl in the buttock on three consecutive days followed by others at longer intervals. Less than half a gram sufficed to cause total blindness—much less than the smallest recorded quantity.

Münchener medizinische Wochenschrift.

October 27, 1914.

Fatal Injury from an Aviator's Darts.—Grünbaum refers to the recent articles about these missiles and is able to report what had at that time been conjectural—death from their use. Among the slightly wounded in a certain regiment was an officer who half an hour earlier had felt a sharp puncture in his shoulder, soon after which he began to suffer from painful breathing. A lesion was found in the right supraclavicular fossa and treated aseptically. He later complained of tachypnea, slight cyanosis, pain in the hepatic region. There was tenderness to the right of the abdomen, abdominal muscles tense. At this juncture a soldier appeared wounded, his foot having been pinned to the earth by a dart which a comrade had at once extracted. No bad consequences are known to have resulted in this second case, but the officer be-

came progressively worse and it was found that he was suffering from a hemopneumothorax. The dart had actually passed downward through the diaphragm. Patient was too ill for laparotomy and died 36 hours after the injury. An autopsy was out of the question but the missile had set up a fulminating peritonitis.

Be Sparing with Dressings!—Kreeke states that in this present war the incapacitated will reach 50 per cent. of the actual combatants! Statistics show beyond doubt that the percentage must increase with the numbers engaged. Half a million of merely wounded in the first year of warfare is a very conservative estimate. The demand for dressing materials will be colossal. General economy must of course be practiced. A small wound may get along with a little mull and adhesive plaster in place of a big wad of cotton, bandage, pins, etc. Padding material must be spared for fractures. Certain mull for fastening dressings in any locality will be found to save the use of long roller bandages, which latter, however useful in peace times, cannot be renewed frequently in the interest of cleanliness. Plaster of Paris dressings with proper fenestration are the most economical for shot fractures. One must as far as possible use any local resources of the countries involved in the campaign, so that importation will be unnecessary, cellulose wool, wood wool and moss may here be mentioned.

Tetanus.—Eunike describes the first ten cases of lockjaw treated in the City Hospital at Ludwigshafen on the Rhein. All but one of the wounds was made by shell fragment or shrapnel. The entire number wounded was 3,000, so that the proportion of cases of tetanus infection was 1/3 of one per cent. which does not seem high and is doubtless much more favorable than the average. The incubation period ran from 9 days to 3 weeks, and in the majority was from 12 to 18 days. The prognosis therefore was not so hopeless as is often the case. Five patients survived—a 50 per cent. mortality. Three cases arrived from the front in a practically hopeless state, death soon resulting. Each patient received serotherapy (no prophylaxis is mentioned) and narcotics (choral). Magnesium was used to some extent and the author will consider this in a later paper. Voelcker also contributes a paper in which some novel features are mentioned. In one case there was considerable difficulty in distinguishing between tetanus and polyarthritis rheumatica, because as a result of arthritis of the temporo-maxillary articulation the jaws were locked. Recently a case with the diagnosis of tetanus was found at autopsy to have had granular nephritis and uremia. The author like his colleage Czerny speaks seriously of amputation but thinks radical disinfection of wounds with concentrated carbolic acid should be tested along with 2 per cent. subcutaneous injections of the same—apparently a concession to Baccelli's method. The initial injection of antitoxin should be given intradurally.

Münchener medizinische Wochenschrift.

November 3, 1914.

Removal of Beards in Women.—Karl Unna reports some excellent results in this direction. After much progress had been made in the technique of epilation the author chanced to learn of Dr. Schwenter-Trachsler's procedure of polishing and at once tested it. He used pumice stone which had been pulverized and compressed. This substance was used while moistened. The powder could also be applied with the finger. Patients could be taught to make applications every evening. At the end of from one to two weeks the skin should have been rubbed clean. The recurrences are always milder and require less treatment. The author combined this mechanical resource with his oxygen method of depilation as follows: by using a peroxide soap (sodium hyperoxide), with which the beard was well lathered for from 2 to 10 minutes. This soap comes in solid sticks. The softened hairs are now attacked with the compressed cakes of pumice stone which are rounded or whetstone shaped, the former provided with handles, and intended to reach depressions and folds. The polishing period lasts from 2 to 5 minutes. The skin is next wiped dry and dressed with cold cream. If but few hairs are present electrolytic epilation, long the best method, as well as the use of the punch are now regarded as too painful. At present these collections of stiff hairs, for example between the eyebrows, about moles, at the corners of the mouth, etc., are given a preliminary depilation with barium sulphide, after which the area is treated with soaping and frictions as already described. If the women have true beards whether of down or coarse hairs, the author no longer uses the needle but pursues only the new methods. Two illustrative cases are given. The first was in a young woman of 23 with luxuriant scalp hair and also hair in all the localities in which it grows on the male face. A hairy area on the cheek had been treated for six months with electrolysis. This was now quite impracticable because of the detention from business and expense. Her betrothed had recently been shaving her. She was placed at once upon peroxide soap and pumice stone. She did not return to the author for six months because she had been perfectly satisfied with the results. She showed great improvement but as she was not entirely free from her infirmity, treatment was made more intensive, and has now continued for a second half year, at the end of which time there was nothing more to be done. Another case less severe and more circumscribed yielded to two months of treatment.

Serotherapy of Tetanus.—Heddaeus, who introduced the intraarterial method of injection of antitoxin does not believe that serum alone can be curative although it is a valuable resource. He has succeeded in curing 6 out of 8 cases and the question of importance is to what extent did the serum contribute to this excellent showing? Antitoxin was given freely and timely in all the cases, but in all but one narcotics were also given. They included opiates including codein, scopolamin, and veronal. He is inclined to attribute his success to a judicious combination of specific and symptomatic remedies. His narcotics are not given by routine but in various combinations and he does not attempt to show any superiority of one drug over another. In reading his reports we note that he gave the first patient chloral and magnesium sulphate, the second choral, opium, scopolamin, and morphine, the third chloral alone. In the fourth no narcotic is mentioned. In the fifth case choral, scopolamin, and morphine and later large doses of opium, etc. The most striking feature about the treatment is the intraarterial injection of antitoxin which was practiced throughout. The author will not say outright that these injections cured his six patients. Subdural injections were also used.

Hydrogen Peroxide and Wound Treatment.—Walther at the head of the Reserve Hospital at Giessen refers to the great number of preparations of hydrogen peroxide, some of them in solid form, which have been used and recommended in the present war. It is the ideal antiseptic yet the ordinary solutions as they occur in warehouses are not completely adapted to field uses. The percentage of H_2O_2 varies from 0.8 to 2 per cent. and it is the custom to make composite solutions of H_2O_2 and boric acid which are readily seen to cleanse the wound surfaces. Most of the solid proprietary combinations also contain each of these ingredients in

variable proportions. Some of these occur in compressed tablets so that solutions are readily extemporized.

Deutsche medizinische Wochenschrift.

October 29, 1914.

Treatment of Tetanus.—Professor Czerny begins an article on this most inexhaustible subject—inexhaustible because every field surgeon has been adjured to report his experience with this military scourge. This war is one of artillery with its shredded, lacerated shell and shrapnel wounds. The soldiers live in dirt, amid human and animal excrement, in trenches which are often ditches; and when wounded, wet and dirty are packed into unclean transport cars, in which they lie for hours before they can receive any medical attention. With a little straw beneath them they are packed like herrings—many of them ill with dysentery. Transportation is so slow that Cologne may not be reached for from 4 to 6 days from the French battlefields. There are indeed some very superior sanitary trains and happy the man who can take one of them and go directly to his home. But not a tenth part of all the wounded can be thus accommodated after the colossal battles of the present war. One is really fortunate to secure any transportation at all. The author believes that the natural animal defenses can dispose of the tetanus bacillus save under special unsanitary conditions. The cold, wet fall weather is really the cause of the excessive morbidity. So aseptic first dressings when practicable, antagonize the infection. When this is out of the question, conservative treatment is doubtless a mistake—amputation immediately performed would no doubt save life at the cost of limb. It is well enough to say give prophylactic serum injections in all suspicious wounds." But the author once saw a scratch on the nose from a rose thorn kill a gardener in six days from the time of the accident. Again a boy received a punctured wound on a finger, which was at once amputated, while serum was injected at the first appearance of the symptoms. Nevertheless, death took place. The worst cases come on without prodromes. The wounds have not yet been dressed, are painful. One sees the patient's face masklike. Speech and swallowing are difficult and trismus is present. In wounds of the extremities local spasms sometimes give warning. There were turned over to the author reports of twenty-nine cases of tetanus treated at the local hospitals before the end of September. Twenty of these arrived within a few days, from the battlefields in Lorraine. In all but one of the twenty-nine cases antitoxin was given, and but thirteen patients died—less than half. This cannot exactly be set down to the entire credit of the serum because Baccelli's method had also been used in four cases and Meltzer's in three. There were also some recoveries in cases in which the incubation period was prolonged, bespeaking a subacute course. Narcotics were freely employed. In summing up the author advises serum prophylaxis at the time of the wound and intensive serum treatment at the earliest period of the disease proper, giving it by all the customary routes. In certain cases prophylactic amputation must be seriously considered. He recommends narcotics for the pains and convulsions, probably including among these magnesium sulphate, as none are specified by name.

Treatment of Tetanus with Magnesium Sulphate.—Falk's article is very brief. The material is in part personal and in part supplied from the notes of colleagues. He refrains from any attempt at analysis and statistics. Before the injections of magnesium he anesthetizes the skin with novocain. That in some cases convulsions seem to increase in number when small doses are injected seems to be interpreted by him on the duality principle that a small dose of a narcotic may behave as a stimulant. This condition may subside spontaneously—if not one can push the magnesium and give chloral. He has never seen a single dose of 9 grains or a daily dose of 24 grains cause any untoward accessory phenomena whatever. A severe type of tetanus does not by any means signify that extra heavy doses of the drug are to be given. It is better to push it in a steady, uniform manner—three injections (subcutaneous) in twenty-four hours as an average. At the acme of the action of the drug, say one hour after injection, there is enough relaxation of the jaw muscles to permit of feeding. The patient can often suggest the time for an injection by the subjective experience that his muscles are beginning to tighten.

Deutsche medizinische Wochenschrift.

November 5, 1914.

Gastrogenic Diarrhea, Achylia Gastrica and Achylia Pancreatica.—Bitdorf recalls that A. Schmidt, through the labors of some of his students (Oppler, Einhorn) established the fact that many obstinate diarrheas are of gastric origin. Schmidt has recently emphasized the occurrence of a certain syndrome—achylia gastrica with intestinal indigestion plus a periodical appearance of pancreatic achylia. This condition is recognized from the stools while patient is on a trial diet. It is purely functional and the inactive pancreas may be made to secrete by injections of pilocarpin. The association of achylia gastrica with achylia pancreatica is very rare, although hypochylia of the pancreas is more frequently found. As a rule in achylia gastrica trypsin may be found in abundance in the stools and also in the stomach by Boldyreff's method of an oil breakfast. In achylia gastrica with severe diarrhea trypsin is usually plentiful in the feces. But in Schmidt's new syndrome the fecal picture alone is not characteristic for mere absence of trypsin and the other pancreatic enzymes with moderate steatorrhea and creatorrhea could not prove its existence. There might be an organic disease or partial compression of the duct; although here the steatorrhea is more marked and the creatorrhea less so.

Treatment of Sepsis in the Army.—Jochmann states that septic soldiers should always be recumbent in order that the heart may be spared; they should lie flat long after fever has left them. Mouth care is necessary in all cases and daily stools should be secured with enemata. Diarrhea may be best let alone, for to check it may be dangerous; naturally if profuse and weakening one of the tannins should be given. For food egg yolks, alone or mixed up with sugar and wine, milk, beef broth, and serial decoctions are recommended. In theory alcohol may be bad or good—bad if it interferes with the natural defense, good if its calories may be reckoned as food. The author believes its actual good outweighs the theoretical objections. It promotes appetite and affects the patient's depression favorably. Women who have never used alcohol seem to profit more from its use in sepsis than men who have a tolerance. Brandy, red wines and champagne appear to be the best forms for exhibition. The drinking of water and its rectal and subcutaneous infusion are believed to favor elimination of toxins. Permanent colonic irrigation is especially recommended. Antipyretic drugs are perhaps contraindicated on account of the weakened heart. If fever is high enough to cause mental confusion, the patient may receive a cool bath, save when thrombophlebitis is present. The evidence concerning the utility of collargol is extremely conflicting. Therapeutic sterile abscess (the French *abcès de fixation*) is worthy of a trial.

Insurance Medicine.

SUGGESTIONS TO MEDICAL EXAMINERS.

BY THE INSURANCE EDITOR.

CONSPIRACY TO DEFRAUD LIFE INSURANCE COMPANIES.

DECEPTION for the purpose of obtaining insurance under false pretences usually occurs in the form of a material concealment or misrepresentation of the answers recorded in the application. A more tangible and flagrant variety of fraud is that of substitution, actuated through a desire for the speedy realization of the end in view. Impersonation is difficult but does occur, and it is, therefore, highly important for the examiner to make careful measurements and observe marks, scars, or peculiarities which may lead to identification in the event of legal proceedings.

The writer had an early personal experience with this form of imposture. It began with an appointment to examine an applicant in the rear room of a barber shop in a locality not noted for a high degree of respectability. The Italian proprietor of the shop, a subagent, was affable and anxious to assist the examiner. The person presenting himself for examination was an Italian without physical flaws. In a few days, a similar experience followed, and the smiling barber seemed delighted with his success as a solicitor. When a request for this same performance came in a third time about ten days later, suspicions were aroused and the company was informed by the writer that he would not be responsible for the personality of these applicants, so further appointments were refused. Another company continued, however, to deal with the same people until suspicious death claims led to a thorough investigation and the disclosure of a conspiracy between the barber, a physician, and an undertaker with some healthy individuals to impersonate invalids supposed to be afflicted with fatal disease. Fortunately the invalids for which the substitution was practised in the three cases examined by the writer did not pass off as rapidly as the conspirators had expected and were still living when the suspicious death claims led to disclosure. The investigation by the other company revealed the plot by which the conspirators paid the premiums and relied upon the deaths of the insured at a fairly early date. The physician and undertaker filled out the death claims.

Other notable cases of substitution are found in the literature of life insurance. The earliest known instance of impersonation was recorded in London in 1780. An application was made to insure the life of a woman for $10,000. The examination and personal history were excellent, so the policy was issued. Within six months a claim was made, consumption appearing in the proofs of loss as the cause of death. The claim was paid, but investigation, started too late, uncovered the fact that one sister, being an incurable invalid, was impersonated by the healthy one at the company's office, who deceived the examiner, and disappeared immediately after receiving the money. In another case, some creditors of a consumptive were anxious to reimburse themselves in advance of this man's death. A healthy substitute was provided for the examination, and policies were issued to the amount of $20,000. The invalid died within a month after the payment of the first premium, too soon for the success of the plan. In still another historical case, the conspirators succeeded in swindling one of the large companies out of $2,000. The policy had been issued two years previously to a certain individual, and at his death the money was paid to his widow. It was discovered later that the insured, a consumptive, had no knowledge of the transaction, and was impersonated throughout the usual preliminaries to the issuance of a policy by another man in collusion with the wife, the substitute receiving half the proceeds.

The collusion of medical examiners with criminals has left a stain upon the profession, but this occurrence is a rare one, notwithstanding the many temptations offered. A notable case is that in which an examiner filled out a blank in the case of a consumptive and gave an unreserved recommendation. The insured wife was innocent in the matter, as the husband arranged the plan, whereby the examiner was to receive $1,000 in the event of death, which was not likely to occur until the period of incontestibility, one year, had passed.

Objection has been made to the publication of the methods for defrauding life insurance companies on the ground that it may prove dangerously suggestive. Schemers, however, do not need much in the way of suggestion, for they are shrewd and clever enough to contrive their own plans. On the other hand, the disclosure of fraud and craft will enlighten the field examiners and the public and thereby lessen the opportunities for these practises. It will, moreover, show that the companies are alert for the detection of crime and determined in their efforts to run down cases of palpable fraud in order that the interests of innocent policy holders may be protected. Many conspiracies similar to those given here as illustrations have occurred in the past, but it is difficult to carry out these prearranged frauds at the present time on account of the improved system of inspection employed by good companies.

Advantage of Insuring Some Types of Chronic Heart Lesions.—Harpole considers that there are many heart cases that are insurable that would make good business for the company, and, in the eye of the expert who is able to give them a thorough examination not only of the heart but of the whole body, in rest and in repose, and to study them thoroughly at different times, they are just as good risks as men with sound hearts. A broad basis would have to be established on which they could be accepted, and rates made on certain selected cases which would be just to the applicant and profitable to the company. The company desiring to engage in sub-standard business and wishing to handle heart cases can create a profitable business by throwing out the dangerous lesions and rating up the safer ones. Upon investigation it would be found that companies would be confined to the acceptance of what are known to be cases of mitral insufficiency, and these can only be accepted when in a state of perfect compensation, and the history of the case and the general health of the individual warrant it. Dr. Oliver Wendell Holmes said that "the way to attain longevity is to acquire an incurable disease." This is a feature of no inconsiderable importance, as such cases save themselves in every possible way, thus raising themselves very closely to the healthy standard. Another element of profit is the tendency of such cases when once they have taken life insurance to remain on the books and loss from lapses is not a feature with them.—Medical Section, American Life Convention.

Book Reviews.

FOOD PRODUCTS. By HENRY C. SHERMAN, Ph.D., Professor of Food Chemistry, Columbia University. Price, $2.25. New York: The Macmillan Company, 1914.

ONE may speak of the present age as one in which the "food-conscience" of the people has been awakened, first, as to food purity, and second, as to food economy. It is surprising how little the average individual knows about the source and the preparation of foods. The present volume supplies a wealth of information on this subject for the general and professional reader. The plan of the work, according to the author, is "to devote a chapter to each important type of food covering (1) an account of its production and preparation for market with such brief statistical data as will indicate the relative economic importance of the industry, (2) the proximate composition and general food value, (3) questions of sanitation, inspection, and standards of purity, (4) special characteristics of composition, digestibility, nutritive value and place in the diet." The subject matter is dealt with under the following headings: the principal constituents and functions of foods; food legislation; milk; cheese and miscellaneous milk products; eggs; meats and meat products; poultry, game, fish, and shellfish; grain products; vegetables, fruits, and nuts; edible fats and oils; sugars, syrups, and confectionery; food adjuncts and unclassified food materials; rules and regulations for the enforcement of the food and drugs act; food inspection decisions; methods and standards for the production and distribution of certified milk; meat inspection law and regulations; and table of 100-caloric portions. The book is eminently practical and no less interesting, and there can be no doubt that it supplies a distinct want. Its value as a work of reference is enhanced by the tables of composition of foods. The data pertaining to food legislation and inspection provide a feature of particularly timely interest.

PRACTICAL BANDAGING, Including Adhesive and Plaster-of-Paris Dressings. By ELDRIDGE L. ELIASON, A.B., M.D., Assistant Instructor in Surgery in the University of Pennsylvania Medical School; Assistant Surgeon, University of Pennsylvania Hospital; Assistant Surgeon, Howard Hospital; Member of the College of Physicians of Philadelphia. 155 original drawings and photographs. Price, $1.50. Philadelphia and London: J. B. Lippincott Company.

THE present volume gives a description of all the bandages in common use, including roller bandages, miscellaneous bandages, elastic bandages, adhesive dressings and plaster of Paris or gypsum bandages. The book is well illustrated, and will prove of service to medical students and nures.

THE PHARMACY HANDBOOK. By F. W. CROSSLEY-HOLLAND, F.C.S., Pharmacist. Member of the Pharmaceutical Society of Great Britain; Member of the American Pharmaceutical Association; Membre de la Société Chimique de France; Fellow of the Chemical Society of London; Associate Editor of "The Prescriber." Price, $2.00. New York: Oxford University Press, 1914.

THIS book is not a work on pharmacy, but it is a useful summary of much that is connected more or less with pharmacy and with which a pharmacist may reasonably be expected to be acquainted. The sections dealing with serums, vaccines, tuberculins, phylacogens, hormones, colloids, and ionic medication are opportune and valuable. The chapter on pharmaco-ethics is interesting, and shows the relation of the pharmacist (in Great Britain) to the physician, to the patient, to clients in general, and to his confrères. It is gratifying to note that the author does not approve of counter-prescribing; but his condemnation of this iniquitous practice is but half-hearted, for he says that advice to abstain from such practice may be regarded as a "counsel of perfection."

OUTLINES OF ORGANIC CHEMISTRY, a Book Designed Especially for the General Student. By F. J. MOORE, Ph.D., Professor of Organic Chemistry in the Massachusetts Institute of Technology. Second Edition. Price, $1.50. New York: John Wiley & Sons. 1914.

THIS small volume is based on a series of lectures which the author has been giving and is intended to present the subject to those who are studying the subject from the non-professional point of view. The organic substances selected for study are chosen because of their practical importance or in some instances because of convenience in illustration. Optical isomerism has been dealt with rather fully as has also the discussion of the construction of constitutional formulæ. The presentation of the subject of valences is especially sane and worthy of recommendation. There is a short but comprehensive chapter on physiological chemistry in which the work of that branch of science is briefly outlined.

THERAPEUTICS OF DRY HOT AIR, WITH A CHAPTER UPON THE INCANDESCENT ELECTRIC LIGHT. By CLARENCE EDWARD SKINNER, M.D., LL.D. Physician in Charge and Physiotherapeutist at Doctor Skinner's Sanatorium, New Haven, Connecticut; Originator and for eight years Physician in Charge of the Newhope Private Sanitarium, New Haven, Connecticut; etc. Third Edition, Thoroughly Revised to Date. Hammond, Indiana: Frank S. Betz Co., 1914.

THIS book makes a strong plea for the wider use of dry and very hot air, either alone or in combination with other agents. This therapeutic measure has in recent years begun to come into prominence, proving its value in a wider range of disease processes than at first imagined. The difference however between clinical success or failure often depends on the technique of its application, which is not so simple as generally supposed; hence, this subject is very important and merits close study. The opening chapter describes the several makes of apparatus. The next two chapters, on Physiological Action and Technique respectively, are especially clear and detailed. Succeeding chapters give the special treatment of different disease processes. The last chapter gives the action of incandescent electric light in comparison with that of dry hot air proper. The book is well illustrated and eminently adapted for instruction in the application of this therapeutic measure.

DIE OPERATIVEN ERFOLGE BEI DER BEHANDLUNG DES MORBUS BASEDOWII. Von San.-Rat. Dr. OTTO KLINKE, Direktor der Provinzial-Heil- und Pflegeanstalt in Lublinitz (Ober-Schles.). Price, 4 Marks. Berlin: S. Karger, 1914.

THIS work consists in a critical review of the history and literature of the operative treatment of goiter based upon studies of what the author calls the older literature, from 1880 to 1894, and the newer literature, from 1894 to 1912; although the 22-page bibliography contains references to selected articles as far back as 1859, while attention is called to earlier compilations covering the literature from 1802 to 1880. The literature of the period up to 1894 shows the gradual development of the theories as to the character and causation of Basedow's disease and the somewhat reluctant acceptance of the suggestion that operation afforded the best promise of its successful treatment. In the second chapter the literature from 1894 to 1912 is taken up year by year and the case for operative rather than medical treatment is gradually made very strong. This is followed by a summary of the operative results in collected cases from 1904 to 1912. These comprise 6,825 cases with Basedow symptoms, in which there were 1,202 cures and 4,653 improved, and 8,992 cases without Basedow symptoms. These statistics are not claimed to include all the reported cases during those years, those from foreign countries especially being incomplete, but the figures are probably representative. Other chapters take up the numerous operative methods, internal medication, etc., while the final chapter gives a résumé of the subject and the author's conclusions, which are emphatically in favor of operation.

The work is an epitome of the subject and embodies the results of a vast amount of research work. In the very extensive bibliography there are relatively few references to the work of Americans who have been among the pioneers in the development of operative treatment, and the names of perhaps the foremost have been omitted altogether.

GYNECOLOGY. Edited by EMILIUS C. DUDLEY, A.M., M.D., Professor of Gynecology, Northwestern University Medical School; Gynecologist of St. Luke's and Wesley Hospitals, Chicago, and HERBERT M. STOWE, M.D., Associate in Gynecology, Northwestern University Medical School; Attending Obstetrician to Cook County Hospital. Price, $1.35.

ALTHOUGH there has been no particular advance in gynecology during the past year, this book contains abstracts of many interesting papers. Frequent pertinent comments by the authors have enhanced the value of the publication.

THE PRACTICAL MEDICINE SERIES, Comprising Ten Volumes on the Year's Progress in Medicine and Surgery, under the General Editorial charge of CHARLES L. MIX, A.M., M.D., Professor of Physical Diagnosis in the Northwestern University Medical School. ROGER T. VAUGHAN, Ph.B., M.D. Series, 1914. Chicago: The Year Book Publishers. GENERAL MEDICINE, edited by FRANK BILLINGS, M.S., M.D., Head of the Medical Department and Dean of the Faculty of Rush Medical College, Chicago, and J. H. SALISBURY, A.M., M.D., Professor of Medicine, Illinois Post-Graduate Medical School. Price, $1.50.

THIS is the second book of the series which is devoted to general medicine. It deals with certain of the infectious diseases such as, typhoid fever, malaria, syphilis and cholera, also the diseases of the digestive tract, liver, pancreas, spleen, and peritoneum. The closing chapter is devoted to dietetics.

DIE AKUTE UND CHRONISCHE INFECTIÖSE OSTEOMYELITIS DES KINDESALTERS AUF GRUND EIGENER BEOBACHTUNGEN UND UNTERSUCHUNGEN. Von Dr. PAUL KLEMM, K. R. Staatsrat, Oberarzt des Krankenhauses vom Roten Kreus, Dirigierender Arzt der Chirurigischen Abteilung des II Stadtkrankenhauses in Riga. Mit 7 Abbildungen im Text und 1 Kurventafel. Price, paper, 9 marks. Berlin: S. Karger, 1914.

IN this monograph we find a most excellent discussion of a subject that is of vital importance to all who have much to do with the surgery of childhood; for there is much truth in the author's statement that osteomyelitis is one of the most frequent surgical affections of the growing individual. Almost any practitioner can make a diagnosis of acute osteomyelitis after the process is well advanced; but by that time there has been extensive destruction of tissues and it is of the utmost importance that these infections be recognized early, for they come under the head of urgent surgery. The author shows that with immediate radical operation the injury will often be limited to a small focus, easily and quickly repaired; but delay may mean not only extensive loss of bone with a protracted period of regeneration and convalescence, but both bone and periosteum may be completely destroyed, while severe general infection is frequent and may be fatal.

Infectious osteomyelitis in childhood is taken up thoroughly, Klemm's point of view, as stated in the preface, being that osteomyelitis belongs to the group of lesions of the lymphatic tissues. In the introductory chapter the foundation is laid for the elaboration of this conception of the disease by reviewing in order the periosteum, the bony framework and the marrow, and the rôle played by each, the physiology and pathology of the marrow, leucocytosis, the relation of inflammation to osteomyelitis, etc. The etiology and pathogenesis are then exhaustively considered and the author's personal material, comprising 320 cases, has been drawn upon for the purpose of showing typical examples to illustrate points brought out in the text. The consideration of general features concludes with a short description of the peculiarities of the disease with each of the more common infectious agents, staphylo-, strepto- and pneumococci, typhoid and colon bacilli; the relation of osteomyelitis to general infection; the diagnosis, prognosis, therapy, and classification of osteomyelitis. Then follows about 100 pages devoted to the consideration of the disease as it affects special bones and regions, and a final chapter of about 40 pages covering osteomyelitis of the joints, particularly the hip, knee, ankle, shoulder, and elbow.

As a whole this monograph furnishes one of the most practical discussions of infectious osteomyelitis that has recently appeared and the subject is presented in a most clear, concise, and interesting way.

STUDIES FROM THE ROCKEFELLER INSTITUTE FOR MEDICAL RESEARCH. Reprints, Volume XIX. New York: The Rockefeller Institute for Medical Research, 1914.

SIXTY-ONE articles are comprised within the present collection of studies, being reprints of articles already published, and representing various investigations in pathology and bacteriology, physiology and pharmacology, chemistry, experimental surgery and experimental biology, and studies from the Hospital of the Rockefeller institute. Mention may be made of some of the important articles, which are as follows: "Accidents following the subdural injection of the antimeningitis serum," by Simon Flexner; "Malarial pigment (hematin) as an active factor in the production of the blood picture of malaria," by Wade H. Brown; "The transmission of *Treponema pallidum* from the brains of paretics to the rabbit," by Hideyo Noguchi; "Contribution to the cultivation of the parasite of rabies," by Hideyo Noguchi; "The influence of temperature on the action of strychnine in frogs," by Thomas S. Githens; "On the action of tissues on hexoses," by P. S. Levene; "Concerning visceral organisms," by Alexis Carrel; "Further experiments on natural death and prolongation of life in the egg," by Jacques Loeb; "Die Bedeutung des Calciums für das Wachstun," by Francis H. McCrudden; "The oxygen content of the blood in lobar pneumonia," by Francis W. Peabody; "The cerebrospinal fluid in syphilis," by Arthur W. M. Ellis and Homer F. Swift; "The combined local and general treatment of syphilis of the central nervous system," by Homer F. Swift and A. W. M. Ellis; "Treatment of pneumonia by means of specific serums," by Rufus Cole; "A study of the cerebrospinal fluid in acute poliomyelitis," by Francis R. Fraser; and "A study of the spirocheticidal action of the serum of patients treated with salvarsan," by Homer F. Swift and Arthur W. M. Ellis.

PEDIATRICS. Edited by ISAAC A. ABT, M.D., Professor of Pediatrics, Northwestern University Medical School, Attending Physician Michael Rees Hospital. ORTHOPEDIC SURGERY. Edited by JOHN RIDLON, A.M., M.D., Professor of Orthopedic Surgery, Rush Medical College, with the collaboration of CHARLES A. PARKER, M.D. Price, $1.35.

AS may be expected the gastrointestinal diseases, the disorders of nutrition, and infant mortality comprise a major portion of the section devoted to pediatrics. The remainder of the book is given over to the consideration of the literature of orthopedic surgery.

THE OPHTHALMIC YEAR BOOK, VOLUME X, containing a digest of the literature of ophthalmology for the year 1913. Edited by EDWARD JACKSON, M.D. Professor of Ophthalmology in the University of Colorado, Assisted by THEODORE B. SCHNEIDMAN, M.D., of Philadelphia; WILLIAM ZENTMAYER, M.D., of Philadelphia; WILLIAM H. CRISP, M.D., of Denver; CASEY A. WOOD, M.D., of Chicago; WENDELL REBER, M.D., of Philadelphia; HARRY S. GRADLE, M.D., of Chicago; ROBERT HENRY ELLIOT, M.D., of London; HUGO W. AUFMWASSER, M.D., of Denver; MEYER WIENER, M.D., of St. Louis; and WILL WALTER, M.D., of Chicago. Illustrated. Published with assistance from the Knapp Testimonial Fund of the Section on Ophthalmology of the American Medical Association. Denver: Herrick Book and Stationery Company, 1914.

VOLUME X of the Ophthalmic Year Book is a volume of 460 pages. It is a great improvement on its predecessor, as all volumes have been over those previously published. It man truthfully be said that the Ophthalmological world owes much to the able Editor of this work, for its conception, production, and progressive betterment. Within these pages is found mention of all, and an able review of very many of the papers on ophthalmic subjects published throughout the world. The subject matter is so arranged that any desired reference may be found with the least possible search, and the grouping such that all the data on a given subject published during the year may be consulted without loss of time. There are numerous illustrations. The biographical notices are a valuable feature of the work. No English speaking ophthalmologist can afford to be without this work.

MANUAL OF THE DISEASES OF THE EYE FOR STUDENTS AND GENERAL PRACTITIONERS. By CHARLES H. MAY, M.D., Chief of Clinic and Instructor in Ophthalmology, College of Physicians and Surgeons, Medical Department, Columbia University, New York, 1890-1903; Attending Ophthalmic Surgeon to the Mt. Sinai Hospital, New York; Consulting Ophthalmologist to Bellevue Hospital, to the French Hospital, to the Red Cross Hospital, and to the Italian Hospital, New York. Eighth edition, Revised with 377 original illustrations including 22 plates, with 71 colored figures. Price, $2.00 net. New York: William Wood and Company, 1914.

THE eighth edition of May's work attests to its continued popularity. It is safe to say that for the undergraduate and for those who desire only a cursory knowledge of the subject of ophthalmology, May's work is one of the very best published. The illustrations in the text and the many excellent colored plates make the volume very attractive. The work is reliable and has the reviewer's hearty endorsement.

Society Reports.

SOUTHERN MEDICAL ASSOCIATION.

Eighth Annual Meeting, Held at Richmond, Virginia, November 9, 10, 11, 12, 1914.

THE PRESIDENT, DR. STUART MCGUIRE OF RICHMOND, IN THE CHAIR.

Some Medical Aspects of the American Negro.—Dr. ROBERT WILSON, JR., of Charleston, S. C., said the negro brought from Africa many diseases and sowed them in the Caucasian race, and that he had been found a fruitful soil for tuberculosis, thus becoming a serious menace in the home. The health of the negro, in a large measure, constituted a public health problem. If we were to solve this problem, we must break ourselves of the habit of taking things for granted and accepting assumptions for facts. We must study the negro after separating the mulatto from the pure stock.

Early Diagnosis of Pulmonary Tuberculosis.—Dr. CHARLES H. COCKE of Asheville, N. C., said he could not too strongly urge the value and necessity of careful history taking, among other things, with the expectation of finding some contact infection, remote possibly, but none the less valuable, for the tuberculin test showed clearly how early one might fall a victim to tuberculous infection, although years might pass before any evidence of disease called attention to the possibility. For the examination the patient must be stripped to the waist, no other examination was satisfactory. Careful palpation did not always elicit the presence of cervical glands, although they should be looked for. Increased fremitus should always be noted, and if found early was at the left apex usually. In percussing, only the most delicate stroke revealed the earliest changes from normal resonance. No examination was complete without careful inspection of the throat with a laryngeal mirror. The *x*-ray was also invaluable both fluoroscopically and radiographically, although perhaps only a small percentage of general practitioners were able to avail themselves of this aid. Of the tuberculin tests, the subcutaneous was the test par excellence where there was no fever, a focal reaction bespeaking active disease, while a febrile reaction alone, unless obtained with the initial small dose, implied a high tuberculin sensitiveness, and consequently almost certain probability of active tuberculosis.

The Significance of the von Pirquet Test.—Dr. THOMPSON FRAZER of Asheville, N. C., drew the following conclusions: (1) A positive cutaneous reaction was less frequent in children than it was once thought to be, the high percentage of reactions obtained being due to the application of the test chiefly to infect the children of the poorer classes, and therefore, a positive reaction was of greater significance than it was commonly supposed to be. (2) While there was an increasing percentage of reactions with advancing years, and a corresponding decrease in the value of the reaction the view usually held, that the reaction had significance only during the first two or three years of life, was not borne out by recent figures, and we should be suspicious of a reaction occurring up to the age of ten. (3) Annual tests should be instituted in the effort to detect early infection, bearing in mind the fact that many if not most cases of clinical tuberculosis in later years were due to renewed activity of old foci, and we should seek by proper means to prevent the development of infection into disease. (4) A negative reaction, negative on the repetition of the test, was valuable evidence of the absence of tuberculosis unless the child was suffering from advanced disease or acute disease, especially measles. (5) Further study of the test was necessary before we could fully interpret the reactions, and in the future it was possible that refinements of technic might enable us to determine with greater accuracy how recent the infection was.

State Policy in the Management of Tuberculosis.—Dr. W. S. RANKIN of Raleigh, N. C., in speaking of the advantages of the combination of cooperative sanatorium and correspondence school, said that neither could accomplish the reduction in the tuberculosis death rate of a state on the same appropriation that would sustain both agencies. The sanatorium could not expect to reach, at least for a number of years and except in a very direct way, more than one-tenth or one-fifth of the consumptive population of a state. The correspondence school would probably reach the majority of the consumptives in a state, but a purely educational attack on tuberculosis was too weak in proportion to the magnitude of the problem. The combination of sanatorium and school was of mutual advantage, the one developing the other. The sanatorium provided out of its maintenance funds a small percentage that could hardly affect its per capita per diem cost which would easily make possible an effective correspondence school, while the latter, in touch not only with the consumptive of the state, but with all the organized interests, political, fraternal, religious, business and social, with which the patient was in touch would abundantly nourish a strong sanatorium. The combination of the two gave the state an educational organization analogous to the ideal system of education in operation in the State of Wisconsin. Our cooperative sanatorium in this system was the central university where about one-tenth of the consumptive population was treated and was taught what constituted the right kind of treatment for consumption. These alumni, on returning home and seeing other cases not being properly treated, enabled the sanatorium reflexively to improve the medical supervision of consumptives throughout the state. The correspondence school, an adjunct of the central university or sanatorium would put the state government in almost personal touch with its entire tuberculous population.

The Federal Government and Our Tuberculosis Problem.—Dr. G. M. COOPER of Clinton, N. C., outlined a plan whereby the National Government should establish a Department of Public Health, saying it should rank with the Army and Agricultural Departments, then let the National Public Health Service, through each state board of health, invite any county that desired to cooperate with it in the work. Such as agreed were to pay one-third of the expense incidental to maintenance of a whole-time, efficient health officer. The state board of health was to pay one-third, and the national government the remaining third. Under this plan the local county government would select the officer, subject to approval by the state and national health authorities. In this manner local self-government would continue to exist and the health officer would have the mail franking privileges, so that he could reach all classes of citizens. Open-air schools and tent colonies in each county would be established, and each county would be the center of a public health school in which preventive medicine would be taught.

Tuberculosis Sanatoria in the South—State, County and City.—Dr. JOHN J. LLOYD of Catawba Sanatorium, Va., stated that the sanatorium was able to accomplish good results for the following reasons: (1) Rest was enforced so long as symptoms remained active. (2) Provision was made for and open air life was insisted upon. (3) Proper food regularly served in abundance was furnished. (4) The patient was placed in entirely new surroundings thus affording complete change. (5) The patient was almost under constant supervision, and therefore, could be more thoroughly taught the extreme importance of attention to details. (6) Observing the progress of fellow patients had a salutary and stimulating effect upon the patient himself. Rest, fresh air, and proper food were the basis of modern treatment of tuberculosis and needed no comment, and an entire change was universally recognized as beneficial in most diseased conditions. The sanatorium was a powerful weapon for prevention from the fact that it isolated patients, but more especially because it taught them about the means of preventing the spread of the disease.

The Pleural Effusions of Artificial Pneumothorax.—Dr. MARY E. LAPHAM of Highlands, N. C., stated that five years' experience with artificial pneumothorax had led her to believe that the tendency to pleural effusions increased with the length of time the compression was maintained, because there was a tendency towards progressive irritability of the pleura in consequence of the punctures and the development of a nervous susceptibility. She had had three types of pleural effusions, those developing without any clinical manifestations and no suggestions of any active process. The fluid collected insidiously and might be first detected by a rise in pressure in the manometer, or by filling the needle, or be heard as a splashing sound by the patient. She called these myocardial effusions. A second class had developed in consequence of repeated traumatisms of the pleura as a result of an acute infection, such as an angina, or of chilling, or from other reasons, commonly associated with ordinary pleurisies. These were called infectious pleurisies. A third class was due to tuberculous nodules and process in the pleural surfaces and these seemed to have been favored by the separa-

tion of the pleural surfaces by the artificial pneumothorax.

Dr. W. S. LEATHERS of University, Miss., said there was no problem in public health that had more aspects than that of tuberculosis. There was no problem that had more difficulties associated with its solution. The best plan of attacking the tuberculosis problem was upon a cooperative basis, as outlined by Dr. Cooper.

Dr. C. W. STILES of Wilmington, N. C., said there were only two questions he wished to refer to in this discussion. One was a potential question. Can you do it? The other was a financial one. Have you got money to do it with? No matter whether one was paving streets, building roads, or fighting tuberculosis, those were the two fundamental questions that lay back of all of the other premises. He took issue with the idea that the federal government was doing very little in regard to this problem. Every pound of meat that came into a State had been inspected by the Department of Agriculture for tuberculosis. The federal government was carrying out certain restrictive measures in interstate commerce according to the law, which was no small contribution to the fight against tuberculosis. Unless the medical profession represented by the State medical society and by the Southern Medical Association were willing to set an example by controlling its own members with regard to spitting, etc., it was foolish to go to the federal government and ask the State to change the Constitution of the United States in order to put local police power into the hands of the federal government.

Dr. CHARLES L. MINOR of Asheville said the von Pirquet test had been misused. He had had cases of full grown adults sent to him on account of a positive von Pirquet. We must not reach the conclusion that because every case reacted to this test it was necessarily active tuberculosis. We must differentiate between latent and active tuberculosis, otherwise there would be great harm done.

Dr. THOMPSON FRAZER of Asheville pointed out the reason why we failed to detect tuberculosis early was because we did not recognize it as a chronic disease with relapses. We did not ordinarily get a case of this disease until it had had one or two relapses.

Dr. W. L. DUNN of Asheville said a firm conviction on the part of the physician was necessary to impress a patient that he was ill with tuberculosis. The average physician was afraid to make an early diagnosis of tuberculosis and say so firmly to the patient, because he was afraid the patient would be unnecessarily treated or his activities would be interrupted.

Dr. E. C. THRASH of Atlanta said that many practitioners had made a diagnosis of tuberculosis from the fact that they got a reaction, and the result was it threw a well person into a panic and perhaps subjected him to many inconveniences, possibly a trip away, while other persons subjected to the test would have the disease. He had seen cases of far advanced tuberculosis that came to him where physicians had told them they didn't have tuberculosis because the von Pirquet or tuberculin test proved negative.

Dr. WILLIAM R. KIRK of Hendersonville, N. C., in speaking of the symptoms of early tuberculosis, called attention to the point that he did not think we should attach too much importance to the temperature curve alone, for very often we got the same character of temperature curve in cases of malignant disease. Recently he had such a case that gave the identical tuberculosis curve, with early morning subnormal temperature and an afternoon rise.

Dr. W. E. DRIVER of Norfolk, Va., recognized tuberculin as a specific, and in the cutaneous or von Pirquet reaction the only aid we had was from a negative standpoint. There were definite conditions in which it did not react in young children, in vague and febrile cases. A 1 per cent. Calmette test was of value from a positive standpoint.

Dr. D. M. MALLOY of Mobile spoke of the method of control of tuberculosis in New South Wales. It was obligatory there upon every physician to report every case of tuberculosis. The law was stringent on this point, and carried with it a severe penalty in the way of a fine, and possibly imprisonment. The reporting of every case of tuberculosis by a physician there also carried with it a reward of five dollars.

Duodenal Alimentation.—Dr. CAMP STANLEY of Washington, D. C., said the greatest field for duodenal feeding was in those cases of gastric ulcer which had not yielded to medicinal treatment, and where the indications for surgical treatment were not clearly defined. The direct aim of this method was to relieve the stomach of all work and to remove the mechanical irritation to a sensitive and disorganized mucous membrane, which under ordinary circumstances was the case when the patient was put on an ulcer diet and food allowed to pass through the stomach. It also obviated the stimulation to gastric secretion which in a large percentage of cases had an excess of HCl, the food in the tube cases passing directly through the duodenum. There was an alkaline reaction. The tube passed into the stomach which in turn passed the food to the duodenum without any further effort on the part of the physician. This method was simple and a comfort to the patient after the first twenty-four hours, in that it accomplished rest for the stomach, maintained the body weight and relieved the gastric distress. The procedure, after the tube was in place was not complicated, and the success of the treatment was now dependent upon careful attention to details. The nourishment must be at body temperature, properly regulated, and allowance made for body temperature, as the movement of liquid through the tube was not very rapid and its temperature was consequently maintained at or at least very near body temperature. The solution must be strained through muslin to avoid the stoppage of the tube at the bulb end. If this precaution was taken, it might obviate the necessity of removing the tube, causing mental and physical discomfort to the patient. In only two of his cases had it been necessary to remove the tube, and when the tip was taken off of the button he found a small mass of white threads and under the microscope they proved to be cotton threads. He learned later that the nurse had used ordinary cut gauze to strain the solution. The tube should be cleaned after each feeding by passing through it a small amount of warm water, followed by a syringeful of air so that the tube might be kept empty. Attention must be paid to the patient's mouth, and a good mouth wash used often.

Dr. J. CLARENCE JOHNSON of Atlanta said the appendix, the gall-bladder, and the stomach had received considerable attention, but this quiet, unobtrusive organ, the duodenum, had been neglected, and yet it was the melting-pot of the alimentary canal. There was no other organ in the body so tolerant as the duodenum. He had used the method described by the essayist not only for feeding, but for systemic medication and for local application to the duodenum.

Dr. PHILIP S. ROY of Washington, D. C., said there was no physician who could not make use of duodenal feeding. It was simplicity itself. The apparatus was not expensive. A point with reference to the diagnosis was the stain test. One could tie a shot to a string and the next morning pull it up, and if he found a stain, it was fair to assume that an ulcer existed. A patient might have cancer, or a juicy mucous membrane, but along with the other clinical symptoms it was an important point in diagnosis. If one added to that the high acidity, which did not occur usually in malignant disease, along with the other symptoms he could make a diagnosis of ulcer of the stomach or duodenum.

The Wealth of Health.—Dr. HARVEY W. WILEY of Washington, D. C., said the Department of Agriculture was spending $100,000 a year quarantining against the foot and mouth disease but this disease is not confined to animals. It often attacked politicians, and every time they opened their mouths they put their foot in it. There were ten States quarantined to protect pigs and cows against disease. But we hardly could think of quarantining against cholera and the plague. This would bring up the spectre of State rights. Only our loved ones would die, not our blooded horses, our registered bulls, or prized pigs. There was nothing so cheap as human life.

Radiotherapy.—Dr. HOWARD A. KELLY of Baltimore gave an address on this subject which was illustrated by numerous slides. He expressed the hope that some day a cure for cancer would be found, although at the present time he had not found radium to be a solution of the problem. Radium was alleviating and had effected many temporary cures, but the principal methods of treatment were a combination of surgery with radium, provided that the case was taken in its incipiency.

President's Address: The Profit and Loss Account of Modern Medicine.—Dr. STUART MCGUIRE of Richmond, Va., said the most distinct profit and loss in modern medicine had come about through changes in medical education, which had been accomplished largely through

the efforts of the American Medical Association, the Association of American Medical Colleges, and the Carnegie Foundation for the Advancement of Teaching. It was recognized that each year a progressively increasing number of low grade practitioners were being graduated by medical colleges and licensed by State governments. An investigation of the medical schools showed that many of them were poorly equipped, had scant clinical material and lacked sufficient funds to procure the necessary time of efficient teachers. To remedy this evil a deliberate and systematic movement was inaugurated to lessen the number and improve the quality of the men who were being added to the ranks of the profession. By moral suasion, by State legislation, and by the combination of the better schools, the entrance requirements were advanced, the number and length of the teaching sessions were increased, the character and scope of the curricula were improved, and the minimum number and approximate pay of the full-time teachers were specified. The result of this movement had been that in the last ten years the total number of medical schools in the United States had been reduced from 186 to 101 and the total number of medical students from 28, 142 to 16, 502. In other words, eighty-five medical schools, weak either educationally or financially, had ceased to teach, and over 10,000 medical students not properly qualified for the profession had ceased to study. While the profit side of the specialist's account was large, still on the opposite page there were some items of loss. The high esteem in which the specialist was held, the pecuniary rewards which his services commanded and the advertising opportunities offered by his position, had made him a victim of imitators and imposters, both inside and outside the pale of the profession, who deceived and defrauded the public. Modern medicine was not responsible for the the quack and charlatans, but it was responsible for the members of the regular profession found in every town and city who claimed to be specialists, but who really did a general practice, and for others who, while they might limit their work to certain diseases, were not qualified as experts and had no more knowledge or experience in their diagnosis and treatment than the average general practitioner.

Oration in Medicine: The Importance of Simpler Methods of Physical Examination in Medicine.—Dr. WILLIAM S. THAYER of Baltimore said that practical bedside examinations should be instituted to test the clinical ability of the applicant and these examinations should be conducted by teachers of medicine. To be a good physician, one must be skilled in the fundamental art of diagnosis. It was the duty of the schools of medicine to see that this art was taught thoroughly by trained and experienced men. Moreover, students should be offered a considerable measure of practical experience in the wards of hospitals before graduation. It was the duty of the state to demand that this experience shall have been had and to offer tests under the control of competent men.

Syphilis in the American Negro.—Drs. KENNETH M. LYNCH and B. K. and G. F. MCINNES of Charleston, S. C., read a joint paper on this subject in which the following conclusions were drawn: (1) In the southern United States syphilis in the negro was a serious problem, affecting probably from 50 per cent. to 60 per cent. of the major class of this people, including day laborers, servants and tradespeople. (2) Negro women were apparently more subject to the disease than negro men. (3) There was no apparent suggestive relationship between a positive Wassermann reaction and high blood pressure in the negro. (4) The ravages of syphilis in the individual were not severe in this study. The diagnosis of the disease was difficult to make in many of this class of cases without the aid of a specific test and in respect to the Wassermann reaction, barring a few doubtful reactions, and three or four negative reactions in suspicious cases, this test proved of great value, verifying the suspicion of the infection. (5) While one or two miscarriages occurred, not more frequently in the syphilitic than in the non-syphilitic, the habit of miscarrying was much stronger in the former. (6) Syphilitic women were not as productive as the non-syphilitic, and their children did not survive as well as those of the latter.

Treatment of Some Typical Cases of Syphilis of the Central Nervous System.—Drs. J. P. MUNROE and A. J. CROWELL of Charlotte, N. C., in a joint paper on this subject drew the following conclusions: (1) Salvarsan seemed to be indicated and proved beneficial in all forms of specific disease of the central nervous system. (2) Salvarsanized serum injected into the spinal cavity added to the efficiency of the treatment in the degenerative types of the disease. (3) In inflammatory conditions of the cord it was risky and perhaps unsafe to use the salvarsanized serum injections. (4) Mercury added to the efficiency of the treatment in most, if not all, cases. It was usually considered as secondary to salvarsan, but in some instances it caused the disappearance of conditions and symptoms that had proven resistant to salvarsan, even though used persistently and in the most approved form.

Treatment of Syphilis.—Dr. E. H. MARTIN of Hot Springs, Ark., said he had proven by numerous doses given to cured patients and to patients who had never had syphilis, that, apart from the idiosyncrasy to the drug in a few cases, a dose of salvarsan had no physiological effect on the body temperature or intestinal elimination. Therefore, the disturbances consistently observed after its administration in the treatment of syphilis were due to endotoxins released from the killed organisms causing the disease, the endotoxins of syphilis caused a rise of temperature or characteristic bowel movements or both. If there were many bowel movements there was not much rise in temperature and conversely. Nausea and emesis were probably drug effects and seemed to be dependent on personal idiosyncrasy, but the changes in temperature and the bowel movements were not drug effects and did not follow doses given to patients who have had sufficient treatment. The absolute cure of a majority of, but not all, cases of secondary syphilis might be accomplished by three intravenous doses of salvarsan. Some secondary cases had been fully sterilized of the treponemata by one dose as proven later by genuine reinfections; many secondary cases were cured by two doses, but to be safe three doses should be given to all cases, and if the slightest endotoxin reaction occurred after the third dose the weekly doses should be continued until it was lacking. The fact that more than three doses were frequently necessary in secondary syphilis could be explained by the probable existence of tertiary colonies which had given no symptoms. The treatment of tertiary syphilis was the same as that of the secondary stage, except that here we had to repeat the doses until all of the colonies were broken up and killed. Usually from five to seven doses sufficed except in cases of cerebrospinal lues. Some cases of bone syphilis required more treatment and a very few cases of old tertiary ulceration of the skin were peculiarly intractable. The treatment of the fourth class of cases, tertiary infection of the cerebrospinal system, did not differ from that of other cases of syphilis except as to the greater persistence required. The final results and the degree of restoration to health would depend upon the extent of damage done by the disease to nerve or brain tissue before treatment was instituted. In tabes many of the most distressing symptoms were evidently caused by not the sclerosis in the cord, but by the area of inflammation around the sclerotic area in progressive cases. Some symptoms would disappear, the progress of the disease would be stopped and the life of the patient would be prolonged and made more comfortable.

Treatment of Tabes Dorsalis and Specific Paresis—Dr. ESTILL G. HOLLAND of Hot Springs, Ark., reported six cases of tabes dorsalis and paresis which were greatly improved by intravenous injections of salvarsan, and said these pathological conditions were amenable to such treatment, no matter what results some other physicians might have had.

Atypical Neurological Syphilis.—Dr. BEVERLY R. TUCKER of Richmond, Va., said that syphilis as a disease might be monosymptomatic or practically pansymptomatic, and between these two extremes it presented in man varied symptom-complexes which might resemble almost any known disease. Neurologically considered, syphilis should be excluded in the diagnosis of every case or else the practitioner would fail in many instances, not only to sustain his reputation but frequently also failed to give the patient, who had entrusted his health to the care of the physician, definite relief.

Dr. E. G. BALLENGER of Atlanta, Ga., stated that syphilis was a very potent cause of heart lesions and of arterial disturbances. If Dr. Lynch would examine carefully for arteriosclerosis in those patients who had had syphilis for eight or ten years, who had been inadequately treated, he would reach the conclusion that syphilis was a very common cause of arteriosclerosis. He had given 2,975 injections, and he could not tell ex-

actly the number of cases he had treated during the primary stage, but he had not yet seen secondary or other manifestations of syphilis follow in those patients who were treated early before the secondary manifestations had developed.

Dr. J. K. HALL of Richmond, Va., said that syphilis ought not to be regarded as a genitourinary disease or a disease which affected the genital organs. It ought not be a disease that should come under the observation of the neurologist because cases came to him too late to be benefited. It ought to be a disease for the general practitioner to discover and to treat early. He had been living among those with late manifestations of syphilis for ten or twelve years, most of them paretics and tabetics, and in spite of the hopeful nature of some of the papers he was convinced paresis was essentially an incurable disease.

Dr. A. J. CROWELL of Charlotte, N. C., had used considerable salvarsanized serum in the treatment of paresis and thought it was perfectly rational and scientific to employ this plan of treating syphilis.

Trachoma.—Dr. C. R. DUFOUR of Washington, D. C., said that trachoma should be a reportable disease and laws should be enacted that those having it should accept treatment. Vaccination was compulsory in most communities, so should the treatment of trachoma be compulsory. This problem was one for the state and the United States Government to take in hand and follow it to a finish. The government was doing good work along these lines, but more hospitals, more physicians and more money were needed. Some, if not all of the states had not the money to carry on this important work.

Dr. JOSEPH A. WHITE of Richmond, Va., stated that once trachoma obtained a foothold among the lower classes it was hard to eradicate, especially if over crowded tenement houses confronted us, as the city grew, and that was almost an inevitable consequence of a rapid increase in the population that was taking place in Richmond. Early recognition of the disease, proper treatment, and the application of the usual hygienic and preventive precautions reduced the risk to a minimum. The State board of health had recognized that the prevalence of the disease in the mountain counties of the State was a danger to be reckoned with, and it was actively engaged in an attempt to stamp out the infection. Total or partial blindness frequently resulted from the disease.

Dr. JOHN A. STUCKY of Lexington, Ky., related his experience with the disease in the mountains of Kentucky, and spoke of the measures for treating and preventing it.

A Plan for the Campaign Against Malaria.—Dr. L. O. HOWARD of the Bureau of Entomology, Washington, D. C., stated that the advance of civilization had increased, rather than decreased, the spread of the disease, because of the construction of ponds and stone quarries, in the still water of which the mosquito found a favorable breeding ground. The present prophylactic measures were too general to be standardized. As showing that the disease was more widespread in the South than anywhere else in the country, he stated that there were 79,000,000 acres of swamp land country, of which 65,000,000 were in the southern states. In addition to that vast territory of swamp acreage there were 150,000,000 acres that needed drainage.

Effects of Impounded Water in the Production of Malaria.—Dr. H. R. CARTER of the United States Public Health Service showed that the great increase in impounded water in the South had resulted in a corresponding increase of mosquitos which, however, could be avoided if the ponds and artificial lakes could be so constructed as to be drained or be cleared of the surrounding brush so as to have wind and wave action. He had suggested that all such impounded waters be placed under the control of boards of health.

The Differentiation of the Disease Associated with Splenomegaly.—Dr. WILLIAM H. DEADRICK of Hot Springs, Ark., said that malarial splenomegaly must be differentiated from that of splenic anemia. This latter condition was as difficult of diagnosis as it was obscure in etiology. It might be well divided into three stages: First, a stage of splenomegaly; secondly, a stage of anemia, and, thirdly, a stage comprehending the Banti syndrome, splenic enlargement, cirrhosis of the liver, and ascites. In the first stage, before the onset of anemia, the diagnosis was very difficult. There was little impairment of the general health. Leukemia and pernicious anemia might ordinarily be eliminated by their blood pictures. Hematemesis was far commoner in splenic anemia than in malaria, and the enlargement of the liver was decidedly more marked in Banti's disease than in malaria. The importance of differentiating enlarged spleen from kidney tumors was impressed by a case once under his observation and which had been diagnosed malarial cachexia, chiefly on the strength of a malarial history and a residence in a highly malarial locality. Exploratory laparotomy disclosed a large sarcoma of the left kidney. In leukemia, especially in the myeloid form, enormous enlargement of the spleen was found. There was nothing characteristic in the splenomegaly of leukemia, but fortunately the blood picture was pathognomonic and the diagnosis might be made in the laboratory without seeing the patient. Hodgkin's disease was relatively rare, but its splenomegaly must be differentiated from that of lymphatic leukemia and of splenic anemia. The spleen was rarely enlarged greatly in Hodgkin's disease. In only a small percentage of cases of pernicious anemia was the spleen considerably enlarged. In one case in which the hemoglobin descended to 25 per cent. the spleen was not palpable nor was the area of dulness perceptibly increased. Cirrhosis of the liver caused enlargement of the spleen which must be differentiated especially from that of Banti's disease. In both conditions there was a cirrhotic liver, ascites, splenomegaly, jaundice, anemia, and hemorrhages. Syphilis in the tertiary stage, aside from its role in hepatic cirrhosis, caused enlargement of the spleen by two processes, gummata, and amyloid degeneration. Amyloid spleen was due to syphilis and to suppuration. When syphilitic it was associated particularly with bone and rectal lesions. The spleen was one of the organs, if indeed not the organ, most frequently the seat of amyloid change. In his experience splenomegaly from all causes was rarer in the negro race than in the white. This was true, notwithstanding the fact that some of the diseases, particularly malaria, syphilis and tuberculosis were common in negroes.

Malaria Carriers and the Important Rôle They Play in Persistence and Spread of Malaria.—Dr. C. C. BASS of New Orleans stated that persons who were not ill and who had not been ill of malaria were the chief malarial carriers. Persons who had recovered from an attack of malaria frequently remained carriers for many months and perhaps years. When an individual was infected with malaria plasmodia the parasites reproduced by an asexual process of segmentation or schizogony if condition were sufficiently favorable. After a sufficient length of time they had multiplied to cause clinical symptoms. With each paroxysm the number increased, unless some influence was brought to bear which interfered. The ideal way to deal with the situation would be to examine thoroughly the blood of all persons in the house and treat the carriers. This would be practical in most instances and the next best thing would be to consider all members of the household, probable carriers and treat them as carriers. Such measures carried out during the cold season were more successful because mosquitoes were not active carriers at that time.

Malaria.—Dr. THOMAS E. WRIGHT of Monroe, La., reported thirty cases of malaria of the estivo-autumnal type, which were treated with quinin intravenously and drew the following conclusions: (1) The intravenous use of quinin in doses of fifteen grams, in a dilution of 250 to 300 c.c. of saline, in the hands of a careful, competent physician was safe. (2) The discomfort to the patient was so slight that it became a matter of small importance and in this respect, when compared with quinin by mouth or hypodermically, was much to be preferred. (3) The number of doses for the different types of malaria, the proper time to elapse between the administration, the exact doses and dilution necessary and safe, the permanency of the relief of symptoms, were problems that would be worked out. (4) The relief from the symptoms in malaria, so often jeopardizing life, might be attained very promptly, safely and constantly by this method.

Filarial Infection.—Dr. F. B. JOHNSON of Charleston, S. C., drew the following conclusions: (1) Filarial infection was extremely prevalent in Charleston, South Carolina. There was no reason for assuming this to be the only place in the South showing such a high percentage of infection. (2) The acetic acid method offered the most serviceable way of detecting microfilaria in the blood. In most of the cases one was able to demonstrate them in the blood during the day as well as at night. (3) In the majority of cases of filarial infection no symptoms might be produced by the worms.

The finding of 19.25 per cent. of filarial infections and 5 per cent. filariasis in four hundred routine examinations was to show that even filariasis was more common than general reports would lead one to believe. Filaria could not be classed as a harmless parasite for certain types of infection had a decided pathogenic effect.

Intestinal Parasites in Adults.—Dr. H. L. McNeil of Houston, Tex., reported fifty cases of intestinal parasites in adults, with a study of some of the symptoms caused by them, and concluded: (1) Indefinite and unexplained abdominal pains or tenderness should make one suspicious of intestinal parasites. Parasites should be suspected in all cases of chronic or subacute appendicitis. (2) The adult negro was practically immune to hook-worm infection in this part of the country. (3) Many apparently normal men, who harbored parasites, were subject to certain indefinite complaints diagnosed usually as indigestion, cramps, biliousness, mild diarrhea, malaria, febricula, grippe, which were really symptoms of the parasitic infections. (4) An otherwise unexplained eosinophilia was good evidence of parasitic infection, even though the parasites were not discovered at the first stool examination, but an absence of eosinophilia did not rule out parasitic infection.

Address: The Public Health.—Dr. R. M. Cunningham of Birmingham, Ala., said that all sanitary regulations among and between the State should be under the laws of the United States, and governmental direction and control was the only feasible method in which a proper regulation for the country at large could be evolved and put into execution. The federal government had jurisdiction over all matters ceded to it by the States, and all of these matters concerned the common welfare. So laws, for the fight against bacteria, should be under the direction of some political unit. Public sentiment was necessary to procure proper laws and to arouse public sentiment there must be education. Sanitary measures must be made political issues. So long as the people were silent, so long would the statesman, who was first a politician, fail to take the initiative. If there were a popular demand for sanitary laws, those running for office would make it as one of the reasons for their election to office. There were four things necessary: (1) to create a desire on the part of the people to know the conditions which affected their health; (2) something specific and definite to teach, not what Socrates or Plato said, but something concerning the health problem; (3) the employment of disinterested and competent teachers; (4) ways and means to reach the public.

The Heart in the Common Types of Liver Diseases.—Dr. Alexander G. Brown of Richmond, Va., said that acute inflammation of the liver was not infrequently the cause of sudden death in case of crippled hearts with weak myocardium. The liver might serve as a reserve reservoir for a dilating heart by driving the blood into the liver and resting the right heart. If the liver was itself a more or less normal organ and the heart was crippled by an organic lesion, with myocardial deficiency, this great organ might serve it well in the hour of its impending failure. In cirrhosis of the liver the heart muscle weakened and dilated. The change was due to toxic and mechanical conditions. The toxic predominated. Syphilis of the liver was worthy of the closest investigation. Late syphilis might display itself in the internal organs without giving evidence of its existence by any outward sign in the skin. The liver was a favorite site when it attacked the organs. When the *Spirochæta pallida* retreated to the liver, producing the varied pathology seen there, it was not infrequent that in the cardiovascular system was set up a concomitant degenerative growth in the endocardium about the aortic opening and in the ascending and transverse aorta, if not in the general arterial tree. With this knowledge one's clinical judgment would be necessarily influenced and therapeutic procedure guided.

The Work of the Council on Pharmacy and Chemistry: Its Effect on Medical Progress.—Dr. George H. Simmons of Chicago delivered an address on this subject in which he pointed out that the fight against fraudulent proprietary medicines during the last ten years had been very successful, and that the activities of patent medicine proprietors in seeking to advertise their wares through the medical profession had very materially lessened.

Antiplague Campaign in New Orleans.—Dr. Rupert H. Blue Surgeon-General, U. S. Public Health Service, said the word plague meant but one plague, the greatest of all the ages. He spoke of the ravages of the plague in Mexico in 1902 to 1903, when two hundred and fifty cases were reported, and of its appearance among the Chinese in San Francisco in 1900, which was its first appearance in the United States. From May, 1907, to January, 1908, it appeared in San Francisco again, and all classes suffered. Out of one hundred and sixty cases, seventy-seven deaths were reported. In 1907 the plague appeared in Seattle, and a year later the epizootic plague made its appearance among the ground squirrels on the coast of California. He recited other facts concerning the outbreak of the pestilence in other parts of the United States, pointing out that no city was immune. The situation became so serious in 1897 that a conference of the nations was held in Venice, and measures were taken to safeguard every port. Another conference was held in Paris in 1903, and forty governments were represented. In 1902 a Pan-American conference was held, and it was recommended that every government represented should notify the other of the outbreak of the plague among its own people. This convention was followed by another in 1909, when it was recommended that every means for the sanitation of seaports should be taken, that all buildings, especially those in which food stuffs were stored, should be rat-proof; that it should be made obligatory that the people should use only galvanized iron garbage cans, and that owners of vessels should rid their ships of rats at periodical intervals. The speaker described how the plague first appeared in rodents and was spread among them and from them to human beings by the flea. It had been clearly demonstrated that the pestilence spreads from rats to human beings, and that the rat was a constant and terrible source of danger. The infection might be kept alive in rats from year to year before it finally reached a human being.

The Old-Time Doctor.—Dr. Cary T. Grayson, Surgeon U. S. Navy, said what wisdom, what patience, what years of toil, what charity, what judgment the old-time doctors showed; what support in sorrow and distress, what companions in joy, what beneficent factors they were in the communities in which they lived. Contrasting their lives and their work with ours, one could not but realize how much we owed to them as examples of what a higher type of men could do and did. They, with their work and lives, had laid the foundation on which had been built the splendid practice of medicine. Their lives had inspired respect and confidence in the profession that to-day was one of the chief factors of our success. We were to-day too apt to measure our success by our material prosperity; they built better and more nobly in the love and filial trust of their patients and the consciousness of trying to their utmost to fulfill the highest privilege of mankind, to do good to our fellow men, from whose efforts our present lives had sprung. In the midst of absorbing activities, we should not forget the gray and careworn brother who still plodded "the trail of the lonesome pine," seeking to carry hope and help to the sick and afflicted in many an unknown field. The old-time family physician, being a broad-minded and greatly beloved and respected citizen, was looked up to for the solution of every problem with reference to life and death that involved the human race from the time of Jenner and including the present day specialism. He solved these problems in a rough and rugged common sense way and thereby placed himself, without any solicitation or effort on his part, in unanimous nomination in the heart and minds of every one he came in contact with.

Heart Arrhythmias.—Dr. E. C. Thrash of Atlanta, Ga., said the principal extracardial causes of arrhythmia were cortical, toxic, mechanical, reflex from pathology in other organs, and vagopathic. The treatment of arrhythmias was as varied as their causes. The treatment of the ones produced by factors external to the heart itself must be based upon methods which would relieve these disturbances. The neurasthenic must be relieved of his neurasthenia; the sufferer from visceral ptosis must have his condition relieved and the mechanical disturbances which interfered with the heart's action must be diagnosed and relieved, if possible. Atropin would not only temporarily relieve these functional disorders, but the fact that it did relieve them aided one in making a diagnosis. This drug would not relieve those of extracardial origin, but would make them worse, as it had a slightly paralytic effect upon the vagus. The lesions which were intracardial must

be treated by directing attention toward the heart itself. If there were any luetic complications they should be treated, and from the writer's experience it was erroneous not to give salvarsan in this form of syphilis as its efficiency had been decidedly apparent in the author's hands. Arteriosclerosis, atheroma, calcareous infiltration, and toxemias played an important rôle in producing these latter lesions and they should be treated according to classic methods for handling such conditions. Digitalis was par excellence the remedy to restore the heart to its normal tone and it should never be overlooked by the physician called upon to treat organic arrythmias.

The Importance of Vital Statistics to the South.—Mr. W. J. HARRIS, Director of the U. S. Census Bureau, said that it was important to householders to know the cause of the death of their negro servants, and this could be accomplished only by accurate statistics. Soon after he was made Director of the United States Census Bureau, he ordered that the negroes and whites should have separate statistics, and he had detailed an employee of the Census Bureau to help the Southern States in inaugurating a proper and scientific system. One of the most important uses of vital statistics was their practical employment for the protection of the public health and for the prevention and restriction of disease. Modern preventive medicine was based on vital statistics, and a sanitary service, whether state or municipal, that was deprived of accurate vital statistics was absolutely handicapped in its work. It was necessary to know when and where a death occurred and its cause, in order that we might know how best to remedy the condition. So long as they were without vital statistics health boards were groping in the dark. The deaths from cancer in 1914 had been greater than during any year before, and vital statistics might be used to prevent such a large percentage of deaths from this dread disease. The registration area in 1913 included twenty-three States the population of which was 63,298,718, or 65.1 per cent. of the total population of the country. Among these States were Virginia, Kentucky, Maryland, and North Carolina. Mr. Harris advised the abolishment of the county system of registration as incomplete and urged the establishment of a local system in its place.

Cancer of the Breast.—Dr. WILLIAM L. RODMAN of Philadelphia gave an address on this subject, which was illustrated by numerous lantern slides. He stated that the proper treatment for cancer was early removal. Much had been said about the *x*-ray and radium, neither of which had been of demonstrable worth from the standpoint of permanent cure. He had not in his experience seen a case of cancer cured either by the *x*-ray or radium permanently. Of those cases reported to have been relieved or cured, the original tumor or growth might have been benign instead of malignant. He believed more in the *x*-ray than in radium, and what had been accomplished by radium had been done better by the *x*-ray. He thought the profession was running after false gods when they gave up surgical operation for these new fads. The speaker said that between 12,000 and 15,000 men and women died annually from this deceitfully terrible disease. If the disease were taken in time, when only suspicion was existent, a cure could be effected; but in the majority—and it was a tremendous majority—of cases the patient came too late, or the diagnosis was made too late, to be cured. A careful study of precancerous conditions should be made and all measures of early diagnosis and precaution should be carried to the ultima thule of safety. Cancer was strictly local in the beginning, as shown by every evidence, clinical, surgical, and indicative. Part of the evidence that it was primarily a local disease was that it was not painful in the first year or eighteen months. It was only when adhesions began and secondary ulcerations appeared that the disease was painful. In the beginning it was strictly painless. The patients ate and slept well and went through the ordinary routine of life as if there were nothing the matter with them. If an operation was performed in the early stages, before the disease had become constitutional, a cure would result. If, however, cancer of the breast were allowed to continue until there was an enlargement of the glands under the armpit, only 25.4 per cent. of the cases would be cured. The disease became secondary, or constitutional, only by transfer from the primary focus, as when it entered and attacked the lymphatic glands. Until this transfer had occurred Dr. Rodman maintained it was strictly local.

NEW YORK ACADEMY OF MEDICINE.

Anniversary Meeting and Reception, Held November 19, 1914.

THE PRESIDENT, DR. WILLIAM M. POLK, IN THE CHAIR.

Introduction.—Dr. WILLIAM M. POLK, in introducing the speaker of the evening, said in part that he wished to explain to the ladies and laymen who were present that this was the occasion when the Academy of Medicine, usually devoted to the scientific study of medicine, endeavored to come into closer contact with the citizens of this great city. He wished to tell them without vanity that the members of the Academy were fulfilling their mission in dealing with the most intricate as well as the simplest problems which were presented to them. They were conscious of the fact that in these days of modern activities the science and art of medicine must not only concern itself with the ailments and defects of the individual, but that it had a mission to perform in the betterment of the city, and they were aware that there was but one man fitted to tell them wherein these duties lay and in what direction they could gain the greatest good for the city, a man they all loved to know and to honor, the Honorable George McAneny.

Anniversary Discourse: Some of the Relations of the Profession of Medicine to the Municipal Government.—Honorable GEORGE MCANENY delivered this address. He declared that to instruct this body of men as their President had indicated would be an unexampled act of daring, for municipal authorities had sat at their feet, taken their guidance, and profited by their teachings to the great advantage of the city. He therefore proposed to talk about the undertakings of the City of New York that were aided by the members of the medical profession, and this could best be done by statistics. There were 8,113 physicians, men and women, in the city, of whom the city employed 650 on salaries and 950 without salaries, making a total of 1,632 in the service of the city. There were also in the city physicians in the State and Federal service. The average salary of the physician in the city's service was $1,372. In addition to the physicians there were a nursing corps and other assistants which brought the salaries up to over one million dollars a year, but after all this was but a little over one per cent. of the city payroll. The speaker then explained the direct and indirect methods of taxation and showed that where the indirect method was in operation the mass of the people took less interest in the expenditures than where the direct method was used. In New York City but eight or ten per cent. of the population paid taxes directly. He then compared the activities of the city twenty years ago, when these were practically limited to police and fire protection, with the varied activities of the present time. Speaking, more especially of the Health Department, he stated that twenty years ago the money expended by the Health Department was $200,000 while at the present time it was about $3,500,000, while the activities of the department reached into the homes, the streets, the schools, the factories, and workshops; it was not merely a watch dog correcting sanitary abuses and watching for epidemics of contagious disease, but was active in eradicating those conditions which produced disease and in carrying on a great social work. In this connection the speaker described some of the work of the Department of Charities and Correction. The hospitals were under the latter and were considered as examples of what hospitals should be in every part of the world. They sent men trained from these hospitals to every part of the world. While their organization was not perfect, the progress had been amazingly good. Three or four years ago they got a small item for social service nurses which enabled them to follow up patients in their homes after they had left the hospitals and this was in the long run an economy as it lessened the possibility of those patients returning to the hospital for want of proper care during convalescence. This was getting at the root of things on the preventive side, and this had appealed to him as a budget maker. The Department of Health had extended its work beyond the enforcement of the Sanitary Code and the control of infectious diseases to laboratory work in bacteriology and to child hygiene. The Bureau of Child Hygiene affected 700,000 children in the city and offered the greatest field for preventive work. This bureau at first met with considerable opposition and was looked upon with suspicion as furnishing a way of giving free medical service, but this impression had gradually been

overcome. Then came the call for dental clinics which also met with opposition, but the need for them had been demonstrated and a number had been established. Children deterred by poor health from keeping up with the school work delayed the progress of their classes and this meant constantly increasing bills, so that in the long run this work for the children meant economy. The work of the Bureau of Child Hygiene was the most splendid work of preventive medicine in the city, and seeing this the city had taken a step further and sought to save the children under school age by lowering the infant mortality. The speaker described the work of Nathan Straus in establishing milk stations and how the city had become a partner in this work and had increased the number of milk stations until there were now fifty-five, and it was to be hoped they would soon have more. By locating milk stations in some districts and not in others and comparing the infant mortality in such districts, they had demonstrated without question the effectiveness of the stations in the reduction of infant mortality. He then spoke of the work in the care and prevention of tuberculosis and expressed the opinion that perhaps there had been too much expenditure in connection with the Seaview Hospital. While conditions on Blackwell's Island were not of the best this would soon be remedied. The campaign against tuberculosis had led to the distribution of knowledge in regard to better living conditions and to efforts to secure better tenement house laws and better working conditions in factories and shops. Though there might be much crudity in the work it should be remembered that to carry it to perfection required much money. Among other of the city activities that aided in securing better health and greater happiness to the people were the playgrounds, public baths, and public gymnasia which were gradually extending their scope and showed that the city was caring for the physical side of life more than hitherto. If the death rate that prevailed in 1880 had prevailed last year there would have been 7,100 more deaths than actually occurred and a much larger amount of illness. The Metropolitan Health Department was established in 1868 and in the decade from 1868 to 1877 there were 154 deaths per 1,000 cases of diphtheria; the following decade the rate was 130; with the introduction of antitoxin it had fallen each decade until from 1908 to 1912 it had reached 32 deaths per 1,000 cases. The deaths from malaria had fallen from 26 per year during the decade 1868 to 1877 to 0.7 during the past five years. The number of deaths from scarlet fever averaged 91 per annum during the first decade while they now numbered 18. The death rate from pulmonary tuberculosis had fallen 40 per cent. from that prevailing from 1887 to 1902. During the period from 1874 to 1883 there were 87 deaths from smallpox per 100,000 population annually; during the last year there was not one. Similar decreases were shown in the death rates from cholera, typhus, and typhoid fever. In 1868 the death rate of the city was 35 per 1,000 population; during 1898, the first year of the consolidated city, it was 20.32; in 1909 it was 16; in 1913, 13.7, and it was estimated that for 1914 it would be 13.5. The mortality rates had been thus reduced not only by the activities of the city through the Health Department but by the advances in medical science, by the better sanitary laws, and the better living conditions. In 1898 the infant mortality was 212 per 1,000 babies under one year of age; in 1904 it was 162; in 1909, 129; in 1913, 101, and it was estimated that for the present year it would be even less. The expenditure of the Health Department averaged 41 cents per person in the Greater City and still there were those who objected to this work as an unwarranted burden on the tax payer. Indeed a few had gone so far as to threaten to take the matter to court. He believed that economy in the salvage of lives and health of the common people added not only to their comfort and happiness but that in a broader sense they were healthier, purer, and cleaner not only physically, but otherwise. The speaker said there was one other point which he hesitated to discuss and that was the effect of preventive medicine on the private practice and income of the physician. It stood to reason that if there was less sickness there was less work for the individual practitioner, but it had been said that the new system of pensions in England had actually increased the average incomes of physicians and it was probable that the positions open to physicians in public health work, workingmen's compensation, etc., offset the loss in private practice. There was one other influence and that was that the output of physicians by the colleges was decreasing owing to the work of the American Medical Association in centralizing and raising the standards of medical colleges. In 1901 there was one physician to every 634 of the population while in 1914 there was but one physician to every 688. In the future the physician would be found more and more in preventive work, for undoubtedly the tendency was to socialize medicine. In looking over the work of the various forces working for the betterment of social and health conditions preparatory to reorganization of the city departments, they had found many faults resulting from a duplication of work, but these were faults due to lack of coordination rather than of efficiency. In this work they hoped that they would do nothing that was opposed to the judgment of the physicians and considered themselves as particularly fortunate in having in their health work such men as Dr. Goldwater and Dr. Haven Emerson. After referring to the work of Dr. Biggs in the State and of the campaign for educating the people in health matters, Mr. McAneny congratulated and thanked the doctors for what they had done for their city and said they held indeed an enviable place in being able to render such service and that in their plans for good city government he hoped that their partnership with the medical profession would not be dissolved.

THE PRACTITIONERS' SOCIETY OF NEW YORK.

Two Hundred and Sixty-Fifth Regular Meeting, Held Nov. 6, 1914.

The President, Dr. Walter B. James, in the Chair.

Removal of Cyst of Cerebello-Pontine Angle.—Drs. C. L. Dana and C. A. Elsberg presented this paper. (See page 1050.)

Dr. Peck asked if the removal of the bone was permanent; was there any attempt at replacement.

Dr. Abbe asked what incision of the dura was made, double or straight across.

Dr. Elsberg said that the bone was permanently removed and no attempt was made at replacement. The incision was straight across; the back of the skull was supported by the occipital muscles. The only symptom which persisted in the patient, and which might still persist, was his deafness. His gait was now normal and he was almost free from subjective symptoms. The swelling of the disks was gradually going down.

Dr. Abbe remarked that this was an admirable case. It showed that cases with the gravest symptoms might be operated upon with the hope of finding something so easily removed as this.

X-ray Findings after Perforating Gastric Ulcer.—Dr. C. L. Gibson presented these cases. He said that the *x*-ray picture of the first case was interesting; it showed a little distortion of the pylorus, but the duodenum was apparently allowing free passage of food. Still more interesting was the six-hour picture showing no trace of bismuth in the stomach. This patient had no gastric disturbance and felt perfectly well. The *x*-ray picture of the second case, six hours after the bismuth meal, showed that there was no retention in the stomach at all. Of the third case no *x*-ray had been taken. The patient was a man of forty-six with a history of lues and alcoholism; the man had made a good recovery after operation and had had no gastric disturbances and now was able to eat anything.

Dr. Meara, in speaking of this subject of perforation said that a patient had come to him with the usual long history of indigestion; there had been nothing in the examination excepting slight rigidity of the right rectus; the next day he had had a severe attack of pain and four days later, when Dr. Meara saw him again, there was a very marked rigidity over the right rectus and sensitiveness in the lumbar region; he had a cough and signs of air and fluid in his chest; there was amphoric breathing over the third space; the diagnosis seemed to be subphrenic abscess and pyopneumothorax from perforation of gastric or duodenal ulcer. Dr. Woolsey had opened a tremendous abscess below the liver and found a perforating ulcer; he had done a gastroenterostomy. Two days later Dr. Meara had taken 8 ounces of pus out of the chest. This was an interesting case of a subphrenic abscess occurring with pyopneumothorax, after perforation of a gastric ulcer.

Dr. Peck said that he agreed with Dr. Gibson's view; many cases healed and remained well when gastroenterostomy was not done; he had had about twenty such

cases himself; he had closed the perforation without gastroenterostomy in more than half of these cases and they remained well; when he did do gastroenterostomy he tried to be guided by the amount of stenosis at the pylorus, if the patient was in good condition; most of them bore gastroenterostomy well, but even without it, there was a good recovery in many cases.

Dr. ABBE asked if there was anything in this series that would support the fact of the constriction of the duodenum at the pylorus causing probable dilatation. He endorsed Dr. Gibson heartily; his experience was based on cases which had been followed for a long time, one patient for 14 years, so that the results were shown to be permanent; this latter case was one in which the man seemed perfectly well; he got out of a train, was taken with violent pain, and collapsed on the platform; he was taken home and given morphine; Dr. Abbe was called to see him twenty-four hours later and found him in a desperate state; at operation the abdomen was found full of fluid and gas was escaping from a perforating ulcer close to the pylorus; Dr. Abbe inverted the opening, as Dr. Gibson had just mentioned, by a purse-string suture that seemed to him at the time almost to jeopardize the diameter of the duodenum at the pylorus; he had then sutured the stomach on to the duodenum; the man made a perfect recovery and had never had stenosis, up to fourteen years; this, Dr. Abbe said, illustrated the permanence and usefulness of this procedure.

Intraspinous Use of Tetanus Antitoxin.—Dr. WILLIAM H. PARK called attention to the fact that the French were reporting good results from the intraspinous use of antitoxin in cases of tetanus. These reports agreed with results which Nicoll had obtained, the last nine cases treated having recovered. The procedure was not new, having been used for a time in Switzerland, about 15 years ago. Where so much antitoxin was required for prevention, as in the present European war, it was too valuable to be used in extra spinal treatment where the effect was practically nil. In reply to questions, Dr. Park said that, in his opinion, the nine cases referred to as having recovered would have died without intraspinal treatment. All were well developed cases with various periods of incubation, one of eighteen days. He had had very striking results with guinea pig inoculations, the animals treated with the intraspinous method, surviving, while those treated by the subcutaneous method invariably died. While it was the custom to give intraspinous and intravenous injections at the same time, he was not sure that the latter was always necessary as the antitoxin passed from the spinal canal into the general circulation very rapidly. He did not think that the results were due to any recent improvement in the potency of the antitoxin, but to its direct application. The essential feature was the intraspinous injection. Three to five thousand units should be injected intraspinously and ten thousand units intravenously. The intraspinous injection might be repeated after twenty-four hours if necessary. For immunization fifteen hundred to three thousand units were given subcutaneously. The immunity lasted from two to four weeks, depending on the rapidity with which the individual eliminated the foreign proteid.

Dr. GIBSON said that he had had two cases recently in which recovery followed the use of antitoxin intraspinally. He had had seven cases of tetanus altogether and the last four had recovered. In the first three cases they had used subcutaneous injections and one had in addition intraneural. Of the cases that died, two had subcutaneous injection and intraneural; intraspinous injection had not been in use at that time. The last two cases had been treated at the New York Hospital and they had recovered more promptly. He had been a little alarmed at first by the reaction, not only of temperature, but constitutional; it almost amounted to collapse; the fluid was found to be a little turbid, but that was often found to be simply a reaction to the irritation. He had been much impressed with the efficacy of the modern methods; his last patient, a boy, was well one week after the intraspinal injection had been given.

Dr. JAMES called attention to the fact that they were trying to give a dose to every wounded soldier.

Dr. ABBE said that this method of spinal injection of tetanus antitoxin had been first used at Roosevelt Hospital, fifteen years ago, by Dr. A. B. Johnson, of this city. Dr. Abbe had had nine cases in one month; in six of these cases the antitoxin was introduced into the ventricles.

PHILADELPHIA NEUROLOGICAL SOCIETY.

A STATED meeting was held on the evening of November 27, in celebration of the thirtieth anniversary of the foundation of the Society. Dr. CHARLES K. MILLS delivered the Presidential Address, which was entitled "Concerning Cerebral Morphology in its Relations to Cerebral Localization," and was illustrated by charts and specimens. He traced the development of knowledge along these lines and pointed out the part that had been played by members of the Society in this development.

Dr. FRANCIS X. DERCUM read a communication entitled "Nervous and Mental Diseases and the Newer Pathology." He pointed out the bearing that infections and intoxications, disorders of metabolism and derangements of the internal secretions of ductless glands had in the development of the phenomena of various affections of the mind and nervous system.

Dr. JAMES HENDRIE LLOYD presented a communication entitled "The Morphology and Functions of the Lenticular Nucleus." He discussed the question from the biologic and evolutional standpoints, and he expressed the conviction that the corpus striatum was a vestigial structure, having in man no important function. He decried the conception of a definite lenticular symptomatology.

Dr. CHARLES W. BURR read a paper entitled "The Psychology of Misers.' He recited the details of a number of historic examples of misers and showed that the peculiar type of individual evolved independently of his social state, his education and environmental influences, exhibiting an exaggerated desire to accumulate money and not for its usefulness or power, but for the sense of mere possession.

Dr. WILLIAM G. SPILLER presented a communication entitled "Remarks on the Central Representation of Sensation." He contended that the several forms of sensation pursued independent paths through the tracts in the spinal cord and accordingly had independent representation in the central nervous system. He presented a man with preservation of touch and temperature sense on the left side of the face, but with absence of pain sense, in conjunction with paralysis of the soft palate and of the vocal hand on the same side. There was a history of syphilis and a positive Wassermann reaction.

Dr. THEODORE H. WEISENBURG presented a communication entitled "The Founders and the Work of the Society." He pointed out the work that had been done in the fields of mental and nervous disease by various members of the Society and of the influence for good that had been diffused by the Society among the medical profession of the country and of the world.

Combined Syphilitic and Tuberculous Infiltration of the Larynx.—D. McKenzie reports the case of a woman, aged 48 years, who came under his care six years ago for tertiary ulceration of the nasal septum, with some redness and thickening of the vocal cords. This was cured by antiluetic remedies. In September, 1913, she returned with a general infiltration of the larynx without edema, ulceration or any other sign suggestive of tuberculosis; but as the patient complained of cough and expectoration the sputum was examined and tubercle bacilli were found. On October 19 an injection of neosalvarsan was made with immediate relief of the symptoms. The voice became clearer and the cough easier. An interesting reaction was observed in the larynx the day after the administration of the neosalvarsan, the mucous membrane assuming a livelier red and appearing to be moister and more succulent. This promise of benefit was not, however, realized. The infiltration increased, and as it was affecting the subglottic region and giving rise to serious dyspnea, the patient was again admitted to the hospital. On November 14 salvarsan was injected, and the same evening an urgent tracheotomy under local anesthesia had to be performed. There was no evidence that the laryngeal obstruction had been increased by the salvarsan. The patient experienced some difficulty with the metal tracheotomy tube, which proved irritating and productive of coughing, and a rubber tube was inserted with immediate relief. The coughing had, however, led to a widespread emphysema of the tissues of the neck and the thoracic walls. Since the tracheotomy the larynx has gradually come to assume the typical aspect of tuberculosis with edematous infiltration of the arytenoids. The galvanocautery puncture has been used once with some benefit.—*Proceedings of the Royal Society of Medicine.*

Books Received.

The MEDICAL RECORD *is pleased to receive all new publications which may be sent to it, and an acknowledgment will promptly be made of their receipt under this heading; but this is with the distinct understanding that it is under no obligation to notice or review any publication received by it which in the judgment of its editor will not be of interest to its readers.*

Therapeutic Hints.

Eczema in Infancy and Childhood.—R. G. Freeman finds that the causes of this condition are excessive food; a badly balanced ration; or irritating food such as eggs, oatmeal, stewed fruit, cake, candy, preserved fruit, or jam. The local treatment, as advised by C. W. Crary is as follows: For facial eczema a mask should be worn, while on the limbs the application should be covered by lint and bound in place. Lassar's paste, made from one part zinc oxide, one part starch, and two parts vaselin, is altogether the most useful application for the skin, especially of the face. It may be rendered somewhat antiseptic by the addition of 2 per cent. resorcin or eurosal. For the dry, chronic eczematous patches on the body or limbs of babies one part tar ointment to seven parts of Lassar's paste is most useful. For the scalp in some cases a diluted sulphur ointment has been found distinctly useful.—*Archives of Pediatrics.*

"Dont's" in the Treatment of Insomnia.—H. Crichton Miller emphasizes three points in the treatment of insomnia: (1) Never let the insomniac drug himself. (2) Never let him know what he is getting or how much. This is necessary, so that the physician or nurse can adjust the dose without the knowledge of the patient. (3) Never under any circumstances allow the patient to go to sleep with the hypnotic by his bedside, with the idea that he will not take it unless he needs to. It means that the patient's mind is started on a train of speculation as to whether he will or will not need the drug, even after the light is out and conditions are favorable for sleep. The patient will probably say: "I will not take it now; I will wait another half hour." The upshot of this is that the wretched patient gets five hours' sleep instead of eight, because during three hours the draught was in the bottle instead of in his stomach.—*Medical Press and Circular.*

Treatment of Recurrent Bronchitis in Children.—C. G. Kerley excludes sugar to a large extent from the diet particularly if the case promises to be difficult. Cow's milk is omitted entirely or skimmed milk is allowed if the case is obstinate. Children three to six years of age frequently gain from three to six pounds after one removes sugar from the diet and gives milk skimmed or none at all. The carbohydrates and fats in vegetables, cereals, and breadstuffs supply all the heat and energy required. Medium-weight underclothing or linen mesh should be used. The child is given a warm bath at bedtime, followed by a vigorous rubbing and sometimes by massage. Inasmuch as the so-called lithemic type is the individual most frequently affected. children of this type are given interval treatment with bicarbonate of sodium alone or with salicylate of sodium. If habitual constipation is present, a free daily evacuation of the bowels is insured by suitable dietetic and medicinal treatment.—*Archives of Pediatrics.*

Cyanide of Gold and Arsenic in the Treatment of Lupus.—Juan de Azúa reports good results following this method of treatment introduced by Bruck. The drug which should be kept in green bottles or ampoules, is used in a 1 per cent. solution. in distilled water and should be injected intravenously in doses of six centigrams. This method has also been employed in the treatment of syphilis, apparently with good results.—*Revista Clinica de Madrid.*

REFLEX DISTURBANCES DUE TO CHRONIC APPENDICITIS.*

BY CLARENCE A. McWILLIAMS, M.D.,

NEW YORK,

ASSOCIATE VISITING SURGEON TO THE PRESBYTERIAN HOSPITAL.

THE ordinary, every-day, chronic appendicitis makes itself evident by local pain with or without tenderness and muscular rigidity over the appendix. Such cases are easy of diagnosis and are rarely mistaken in these days. More puzzling are those patients with distant reflex disturbances, due to chronic appendicitis, where there are mild or no local signs to focus one's attention upon the appendix. There may be no local pain whatsoever nor any muscular rigidity, and with but slight, if any, local tenderness.

We may tabulate these reflexes as follows:

1. Pain type—colics in children, simulating gastric or duodenal ulcer; simulating gallstones.
2. Nausea type.
3. Vomiting type.
4. Gas type.
5. Intestinal type—toxemia producing anemia; chronic constipation; chronic diarrhea and colitis.
6. Bilious or toxic type—headaches.
7. Neurasthenic type.

1. *Pain Type.*—Grouped under the first, or pain type, are several classes. First are those patients, particularly children, who have recurring attacks of abdominal pain, colics, with or without vomiting, unaccompanied by fever, lasting but a few minutes or hours. The pain may be localized about the navel or radiate generally over the abdomen. In some of these patients the attack may finally culminate in an acute attack of appendicitis. Following the removal of the appendix nothing further is heard of the colics.

In other patients the symptoms resemble those produced by duodenal or gastric ulcer; that is, pain referred to the epigastrium, which is variously described as gnawing or gripping, coming at definite intervals, two or three hours after eating and occasionally relieved by vomiting. In some cases there is a history of gastric hemorrhage. The cause for such recurring distress is a reflex protective spasm of the pyloric sphincter, which is of itself sufficient cause for pain. This spasm is called forth by irritation from the chronically inflamed appendix. This, however, is made even worse by a chronic hypersecretion which almost regularly accompanies the pyloric spasm. Without local signs over the appendix, the exact diagnosis may not at once be accurately made. A process of exclusion will have to be gone through with, and it may take some little interval before a correct diagnosis is arrived at. Evidence is accumulating to show that the cause of gastric and duodenal ulcers may be the absorption of toxins or bacteria from the lower intestinal tract. This opinion seems strengthened by the frequent association of gastric and duodenal ulcers and chronic appendicitis. Mahnert found that in 64 per cent. of his gastric ulcer cases, there was an inflammatory process in the appendix. He regards the ulcers as due to an embolic process from the thrombotic veins of the omentum, the appendix, and its mesentery. Fenwick states that about 12 per cent. of all continuous fasting hypersecretions are due to chronic lesions of the appendix. Paterson calls attention to the frequency with which appendicitis coexists with duodenal ulcer. Obvious appendicular disease was present in 66 per cent. of cases in which at operation duodenal ulcer was found. In none of Patterson's cases was there any clinical reason to suppose the existence of disease of the appendix.

In case physical examination does not reveal any local tenderness in this pain type an absolute diagnosis may not be at once possible.

One of the most practical rules given by Lockwood in distinguishing between ulcer and appendicular gastralgia is afforded by the behavior of the patient with supposed ulcer during his ulcer cure. If after two weeks of treatment the original symptoms persist, even though they be in a less severe form, chronic appendicitis must be considered possible.

Hematemesis is frequent in appendicular gastralgia and may be alarming in amount. Its combination with epigastric pain may give the exact picture of gastric ulcer. Lockwood believes that many of the hemorrhages are due to traumatism of the pyloric mucous membrane caused by the spasm, which results in a lack of vitality of tissue and the production of minute, superficial erosions, due to self-digestion.

On account of the belief that duodenal or gastric ulcers as well as gall-bladder disease may arise from, or be associated with, chronic appendicitis, it would seem wisest to always remove the appendix whenever one is operating for any of these lesions.

In this pain type there is a class whose symptoms may be indistinguishable from those caused by gallstones. Such patients have more or less prolonged, dull, either mild or severe pain in the epigastric area, right hypochondrium or whole liver region. These patients pass through prolonged, steady attacks, while between times comparatively good health may be enjoyed. During the attack dyspeptic symptoms are prone to be present, such as upward pressure of gas and considerable distension, eased by belching and vomiting. If there are no local signs, such as tenderness, then one can scarcely make a positive diagnosis. After prolonged and unavailing medical treatment,

*Read before the Hospital Graduates Club, October 22, 1914.

an exploratory laparotomy may discover that the cause of the whole symptom complex was due to a chronically inflamed appendix.

2. *Nausea Type.*—The single symptom of appendicular disease may be an obstinate, nagging nausea of a low grade, constant intensity. It has no fixed time of occurrence, and is not made worse by eating. These patients are considered to be instances of nervous indigestion. Medical treatment is of little avail.

3. *Vomiting Type.*—In this type of chronic appendicitis there is vomiting, one or more times a day after eating, or without reference to meals. This is continued over long periods of time. The patients remain in good nutrition and appear healthy outwardly. The vomiting of blood has been mentioned already. Medical treatment for this vomiting type is of little benefit.

4. *Gas Type.*—This is an important class of cases. The sole complaint is gas in the stomach, two or three hours after eating, giving rise to discomfort and even pain, until relieved by free eructations. Medical treatment is of little avail.

These are the distinctive dyspeptic classes of patients, with a very brief, merely suggestive mention of their symptoms. All possible combinations of these various types may be present. It is unfortunate that in the majority of instances the examination of the fasting stomach and of the test breakfast in chronic appendicitis may show no abnormalities whatever. The number of patients with hyperchlorhydria, anacidity, or achylia is about in the same proportion as the average run of patients with indigestion (Lockwood). It must be remembered that a functional hyperacidity is not accompanied by either heartburn or pain, and the occurrence of either of these symptoms should suggest an organic origin. More important is the examination of the fasting stomach for the detection of a chronic hypersecretion. Lockwood says that mild hypersecretion is three times more frequent with chronic appendicitis than in the general run of dyspeptic patients.

5. *Intestinal Type.*—Appendicular toxemia producing a mild, secondary anemia. This type was brought to my attention by Dr. Harold Barclay. The principal symptoms are fatigue, mild digestive disturbances, mostly characterized by gas, which is independent of food. Bowels may be apparently normal but after a cathartic there is material found in the rectum, indicating mild constipation. The fatigue increases so that ordinary exertion is very wearisome. The hemoglobin may be found down to 60 per cent. and the red cells as low as 3,500,000. The ordinary treatment of a patient with such symptoms is usually iron. This is quite wrong as it increases the constipation and consequently intensifies all the symptoms, which are those of intestinal toxemia. The patient should be put upon daily colon irrigations and given a purin-free diet, and injections of arsenic. A teaspoonful of a mixture containing salicylate of soda ʒii, phosphate of soda ʒss, sulphate of soda ʒx, should be given before breakfast, dissolved first in hot water. If there be no local symptoms such as appendicular tenderness, the diagnosis can be arrived at only by attempting the above treatment and watching the results. If the toxemia be due to a diseased appendix, then there will be but slight response to the above medical means, or an advance will not be held for long and there is a prompt relapse into the former condition. On the removal of the appendix the blood promptly returns to the normal and the fatigue disappears, as well as the remaining toxemic symptoms.

In this intestinal type must be mentioned those patients whose sole symptom is either constipation alone or this is accompanied by more or less vague gastric symptoms, such as are generally described as discomfort, or a sense of fulness in the epigastrium, usually coming after meals. They complain of the symptoms of gastric atony. There is no actual pain. An instance of this type is the following patient:

G. R., male, 26 years of age; total abstainer from alcohol, and uses tobacco moderately. His present condition dates back some six years, when he was a senior at college. At that time his bowels gradually began to be constipated. He became unable to sleep, lost appetite and weight. He had consulted several physicians, who regarded his condition as due to neurasthenia. He was under the care for four years of Dr. Harold Barclay, who sent him to me. His complaint was of discomfort in the epigastrium occurring within 15 or 30 minutes after ingestion of food, and of constipation. Repeated physical examinations always proved negative. In December, 1911, I performed exploratory laparotomy. The large intestine was normal. No Lane's kink of the small intestine and no Jackson's membrane were found. The appendix was long and much thickened and contained one-half dram of mucopus. It is now almost three years since the operation, and the patient writes that his bowels are moving normally daily, that he has gained 15 pounds in weight, and that he suffers from no indigestion at any time. There had never been any local focal symptoms.

In this instance the intestinal motility was depressed by reflex irritation arising from the appendix. In other instances there is increased peristalsis originating in the same cause, producing diarrhea. This may not be accompanied by any other gastrointestinal symptoms. In some cases the movements contain varying degrees of glairy mucus, mixed with the stools. At times this mucus is in shreds, having the appearance of small particles of moist tissue paper. These diarrheal attacks alternate with periods of normal movements or constipation. The stools are often preceded by some cramping pains over the lower half of the abdomen. An instructive instance of this diarrheal type is the following:

A barber of 30 years of age had had for four years sudden attacks of diarrhea when he stood up by his chair. Never had had any pain nor obstructive symptoms, nor had he ever passed any blood, but occasionally a little mucus. Never had had any diarrhea at night. He could abort an attack by lying down. No tenderness over the appendix. By exclusion it was considered probable that the appendix was at fault, so in November, 1913, I removed that organ. It showed chronic changes in its walls and contained four concretions. There was also found a distinct Lane's kink in the ileum, three inches from the iliocecal valve. This was straightened out. News from this patient, eleven months after the operation, shows that he was cured by the appendectomy. He has had no diarrhea since, and follows his occupation, which requires standing all day, without discomfort.

There has been much discussion as to the relationship between chronic appendicitis and chronic colitis. There is positive evidence that chronic appendicitis may cause colitis. Mr. Lockwood of England has recently recorded three cases of colitis in which the removal of a chronically inflamed appendix resulted at once in the disappearance of all the colitis symptoms; in each of the cases the appendix contained septic material which periodically escaped into the cecum. Chronic appendicitis can apparently give rise to colitis in three ways: (1) By the inflammation spreading from the appendix

directly to the cecum, ascending colon, and transverse colon; we have evidence of this in many cases of chronic appendicitis. (2) As a result of appendicitis, adhesions may form between the appendix or cecum and other parts of the colon, usually the sigmoid, producing kinks and angles, which result in a local inflammation of the mucosa, which spreads to other portions of the colon. (3) The inflamed appendix acts as a septic focus which is constantly discharging septic material into the colon. It would seem as reasonable to consider this sepsis a cause of colitis as to regard gastric ulcer and gastritis as a result of septic conditions of the mouth and teeth. In the beginning of an attack of colitis there is usually tenderness over the whole course of the colon. Very frequently all the tenderness will disappear except that over the appendix, where it persists. This is an indication that the appendix is involved. The quickest way in such a case to cure the symptoms is to remove the appendix. Recurring attacks of colitis are frequently due to chronic appendicitis, and such attacks may only be permanently cured by removing the appendix.

6. *Bilious or Toxic Type.*—This type is characterized by severe periodic headaches, with occasional attacks of nausea and vomiting. There may be no so-called digestive symptoms other than nausea and vomiting. Between the times of headache such patients are well, save for more or less persistent constipation. An instance of this type is the following:

H. S., female, of 21 years of age. Began to have headaches at 14. She wakes up with intense pain over right eye. There is nausea and she vomits food eaten the previous night. She feels prostrated for the remainder of the day. Three years ago she was put upon a milk diet and was free from headaches for three months, until she returned to solids. Bowels very constipated. For past two weeks she has been in bed and on a milk diet with colonic irrigations. Examination of test breakfast shows nothing abnormal. Examination of a stool shows much free starch and large amounts of mucus. There was persistent tenderness over the appendix and ascending colon. Dr. Harold Barclay transferred the patient to me for removal of the appendix, which was performed in April, 1912. The appendix was chronically inflamed, irregularly thick and its mucous membrane resembled granulation tissue, extending along the side of the appendix and cecum was a definite Jackson's membrane, which was divided. Two and a half years after the operation, the patient considers herself well. She has an occasional mild headache on getting tired. Her bowels are acting normally. Examination of the feces shows them now to be perfectly digested.

7. *Neurasthenic Type.*—An instance of this is the following:

A woman of 38, with a nervous temperament, was seen November 30, 1913. For 13 years had had attacks of abdominal distension in the early morning, which came on without reference to food. By belching she would try to bring up gas, which attempts would make her so nervous that she would then become nauseated and would vomit. There was no pain other than the discomfort caused by the distension. The patient gradually became more nervous and more irritable. She dreaded seeing people so much that she did not go out alone, and her fear was so great that she would not board a train or auto or street car. She was melancholy and depressed. Bowels were very constipated. The toxemia was treated medically and under this treatment the bowels became regular but the gaseous distension still kept up. An *x*-ray picture showed nothing but a retaining of the bismuth in the cecum, ascending and transverse colon for 72 hours. The stomach emptied itself normally. There was considerable intermittent tenderness over the appendix. This organ was finally removed. Its tip was adherent in its distal half and it was obliterated. There was a small ulcer in its base and it contained several fecaliths. After four months the bowels are now acting normally, the nervousness has practically ceased and the gas is improving rapidly.

In the October, 1914, issue of the *Amer. Jour. of the Med. Sciences*, there is an article by Friedman in which he attempts to differentiate by means of examinations of the blood between gastric ulcer, duodenal ulcer, and chronic appendicitis. The results are based on fifty operatively demonstrated cases. The conclusions in the main are as follows:

Gastric ulcer		Duodenal ulcer	Appendicitis
Pyloric group	Nonpyloric		Large mononuclears
Anaemia	Polyglobulia		
Absence of leucocytosis	Leucocytosis	Polycythemia	Transitionals Leucocytosis
Relative eosinophilia	Absence of eosinophilia		

If Friedman's conclusions are sustained, then we may find help in examining the blood so far as making a differential diagnosis is concerned. As for my own conclusions concerning results obtained from the blood examinations, I may say that such examinations have, as a rule, yielded very little positive help in making a diagnosis in chronic appendicitis or gastric ulcer.

The above are the types of reflex disturbances, as I have seen them, which are caused by chronic appendicitis. I do not maintain that it is a complete list whatsoever. It will serve, however, as a warning to our medical brethren not to use the words nervous indigestion, neurasthenia, gastralgia, intestinal toxemia, bilious headaches, and similar terms as indicating a functional disturbance only unless an organic basis has been ruled out absolutely.

In appendicular gastralgia most cases are cured by the removal of the appendix. Paterson makes the assertion that in from 10 to 12 per cent. of appendectomies for chronic, reflex disturbances, this operation is not followed by relief. He explains this by the fact that a gastric ulcer (superficial) may have been present which, at the time of the exploration, was not discoverable on external examination. The sequence of events in such cases is this: 1, appendicular disease; 2, erosion of gastric mucosa; 3, then superficial gastric ulceration (so-called medical ulcer); 4, and later a recognizable, indurated ulcer. In such cases a second exploration might be justifiable. If there are external evidences of a gastric ulcer being present, then a gastroenterostomy would be in order. If no such evidence is discoverable, then it would be proper to open the stomach wall itself so as to positively ascertain whether a superficial erosion or ulceration were present or not. No gastroenterostomy should be performed in the absence of a demonstrable lesion. Perhaps the majority of conservative surgeons would hesitate about performing this second exploration but it is conceivable that the symptoms might become so severe as to require its being performed.

32 East Fifty-third Street.

THERAPY OF FEVER IN PULMONARY TUBERCULOSIS.

By EDWARD N. PACKARD, JR., M.D.,

SARANAC LAKE, NEW YORK.

On theoretical grounds the artificial reduction of fever would seem to be contraindicated. Vaughan[1] believes that practically all fevers are "protein fevers," *i.e.* the infecting organism constitutes a foreign protein which is split up into its finer parts

by either general or specific enzymes formed by cells outside the digestive tract. The non-specific proteolytic enzymes are normally present in the body and constitute the most important factor in racial and individual immunity. Those protein molecules which escape the action of the general enzymes stimulate certain parenteral cells to produce a proteolytic enzyme which is specific for that particular foreign protein. Fever itself is produced by (1) the activity of the cells to produce this enzyme, (2) the cleavage of the foreign protein, and (3) the reaction between the products of this digestion and the tissues, especially when an active and virulent poison is liberated.

Fever must be regarded as a conservative process. Its purpose is the disposal of foreign and dangerous material.

Although fever may be a "beneficial reaction," yet we are justified in doing all that is within our power to limit or control the introduction of the injurious substances causing this reaction, and to conserve and aid the body to overcome the poisons stimulating the tissue cells.

In general, the therapy of any fever consists in removing, or limiting, the cause of the fever; or reducing the fever itself by drugs, hydrotherapy, and other measures.

Unfortunately it is impracticable, and often impossible, to remove the foci of disease in a tuberculous lung on account of surgical and anatomical difficulties; but we can limit the absorption of tuberculoprotein from these areas by at least two methods. The first is functional rest of the lungs by means of rest in bed; the second is mechanical rest of the lungs by means of artificial peumothorax, or the more severe operation of thoracoplasty and pneumolysis. Other means for attacking fever are the dietetic and hydrotherapeutic measures, and, more indirectly, vaccines, tuberculins, and drugs.

Rest.—The value of rest in pulmonary tuberculosis has not been generally appreciated. The surgeon has long made use of this principle in the treatment of tuberculous joints. He finds that his success depends upon his ability to immobilize the affected parts. Why this treatment has not been applied more vigorously in the past to pulmonary cases is probably because the outward signs and symptoms of the consumptive have overshadowed and masked the underlying cause. Both physician and patient have noted the pallor, the loss of weight, and the loss of strength. The advice has been to get out into the country, to breathe deeply, and to take long walks in order to build up. Had the patient a turberculous knee he would not have received such advice. The leg would have been put in a cast for months. If active infiltration of an apex, or an ulcerated area caused pain with every movement of the lung, patients, no matter how strong or robust, would remain exceedingly quiet.

In any tuberculous condition rest of the affected part is the indication. Under certain conditions absolute rest of the lung can be obtained by artificial pneumothorax. But this form of treatment is applicable to a comparative few, while for the vast majority of febrile tuberculous patients rest in bed is the great antipyretic. The respirations are diminished in number, the heart is slowed, and the lung is given functional rest. Thus the absorption of tuberculoprotein is limited, and the "fever reaction" is directly affected.

It has been estimated that the normal man at labor produces several hundred per cent. more heat than when he is at rest.[2] It is especially important then that the muscular exertion of febrile patients be limited to the minimum.

Whatever the degree of fever rest in bed is indicated. Paterson[3] believes in the complete immobilization of the patient. That is, the patient is not allowed to leave the bed but must use the urinal and bed-pan; he is fed; he must not raise his arms but must keep them at his sides; he is denied visitors and reading matter. In other words, "he lies like a log." This treatment is applied to those patients previously afebrile who suddenly have a fever of supposedly tuberculous origin. Of course in the chronic type of fever this measure could not be so completely carried out, although Paterson enforces the strictest rules for a time. With low-grade fevers certain indulgences may be allowed, such as the use of the toilet, washing or shaving oneself. Perhaps when the fever does not rise above 99.5° the patient may sit in a reclining chair for a good share of the day. With fever above 100° the bed should be used and muscular movements limited. With high fevers the patient should be waited on for everything.

Moreover, rest in the open air has its great advantages. Cold air acts as an antipyretic and has a markedly soothing effect upon the cough. Coughing is vigorous exercise and produces upon the lung an effect directly opposite to that which we wish to attain. Therefore, cough sedatives should not be withheld.

As to the value of rest in fever the figures of Burton Fanning[4] are interesting. He found that of 716 sanatorium patients at rest 50 per cent. lost their fever within a period of one month.

Artificial Pneumothorax.—One of the great advantages of this form of treatment is the relief which it affords from such distressing symptoms as fever and cough. Unfortunately the benefits to be derived by its use can be applied to but a limited number of the tuberculous. At present its usefulness is confined to rapidly advancing unilateral cases, or far advanced cases with limited disease on the "good" side, and for uncontrolled hemorrhage. Fever *per se* is not an indication for collapse therapy, but chronic fever associated with other signs and symptoms favorable for pneumothorax treatment is a strong argument for its use.

The reduction of temperature following the injection of gas depends more or less upon the extent of the collapse established. Complete collapse with no active disease on the other side, and no complications, reduces the temperature to normal. Even with a partial collapse fever and cough are often markedly reduced.

From personal observation of twenty-three cases running fever before the beginning of the treatment, eighteen, or 78.2 per cent., showed a reduction of fever following the establishment of the collapse.

Dunham and Rockhill[5] report a reduction of fever in ten out of fourteen of their cases, or 71.5 per cent.

Samson's[6] report is still higher, showing a reduction of fever of varying degrees in fourteen out of sixteen cases, or 87 per cent. These cases were complicated by nephritis, exudates, etc.

The literature upon artificial pneumathorax is very extensive. Reports from all sources agree as to the power of collapse therapy to alleviate symptoms. In general, it may be said that the treat-

ment will cause a temporary or permanent reduction of fever in at least 75 per cent. of all cases favorable for the injection of gas.

If fever is a sign of active disease, these figures are very significant.

Thoracoplasty.—In connection with mechanical rest of the lungs mention should be made of the more radical operation of thoracoplasty. Sauerbruch, L. Spengler, L. Brauer, and Tuffier are the chief exponents of this treatment. It is the extrapleural method of collapsing the lung by a resection of ribs on the affected side, causing that side to fall in, and so restrict lung movements. Baer[7] of Davos has devised a scheme of resecting a rib over a cavity, then by pushing in the parietal pleuræ he forces the walls of the cavity together. The hollow created between the pleuræ and the ribs he fills up with paraffin or fatty tissue.

Sauerbruch[8] reports a favorable effect upon the fever after thoracoplasty. The temperature is raised immediately following the operation, but later it gradually and steadily falls. His statistics are interesting, especially when we bear in mind the fact that the majority of his cases were far advanced. Of a total of seventy-five cases, two died at operation, eleven died at varying intervals later, seventeen were healed, nineteen greatly improved (of these six to eight were practically cured), nineteen were improved; four remained unchanged, and three were made worse.

Surgery of the lung is at the beginning of its development, and no doubt in the future it will be of great benefit to many.

Vaccines.—The great excursions of temperature seen in the advanced stages of tuberculosis, coupled with the fact that in the sputum of such cases there are often found large numbers of organisms besides the tubercle bacillus, led Koch and his school to interpret this condition as septic in nature, and due to a mixed infection in the lung. Pettit,[9] and Brown and Petroff[10] have reported positive blood findings in many tuberculous cases.

On the other hand, Radcliff's[11] detailed investigations tend to minimize the occurrence of mixed infection. From a number of conclusions which he makes I take the following: (1) In the majority of cases of advanced tuberculosis of the lung the tubercle bacillus is the sole infecting agent. (2) Secondary infections do play a part in pulmonary tuberculosis in a small percentage of cases. (3) The temperature curve is useless in determining the presence or absence of a secondary infection. (4) In all cases (except one) no effect was produced on the clinical picture, or on the course of the disease by autogenous vaccine treatment, in spite of the fact that the opsonic curve showed an immunizing response to the inoculation of a mixed vaccine.

Radcliff thinks that some good can be accomplished by vaccine treatment against secondary infections, but that the temperature and general condition of the patient is due to the rapidly advancing tuberculosis, which is the important factor in these cases.

Do vaccines made from the predominating organism or organisms in the sputum have any effect upon the temperature?

Hudson[12] reports upon four hundred cases of pulmonary tuberculosis treated with vaccines. In 70 to 80 per cent. no result was produced, either good or bad. A few among the remaining were markedly benefitted, the rest seemed to show more or less general improvement with the fever "abating a degree or two." It is difficult to interpret from these results the value of the vaccines, for all the patients were following at the same time the routine measures of treatment.

Riviere and Morland[13] have employed vaccines as a routine procedure and have seen benefit from their use.

The time and trouble required to make a vaccine, the uncertainty as to the exact organism supposed to be causing the symptoms, and the lack of abundant positive results following its use, have kept the majority of clinicians from using autogenous vaccines more generally. But it is a method of treatment worthy of trial in stubborn cases.

Tuberculin.—By some authorities tuberculin is considered an antipyretic. It should, however, never be used until less drastic measures for reducing fever have been tried. At least three to four months' rest in bed should be required before tuberculin is injected for its antipyretic effect.

Not every type of fever should receive tuberculin. Early cases with low-grade fever should be kept quiet, depending on rest to reduce the temperature. Higher grades of fever do not do well under tuberculin treatment, whether this fever is considered due to "mixed infection" or not. Far advanced cases with fever are too saturated with their own tuberculin to respond to the outside stimulus. The fever which responds most readily to tuberculin is the low-grade, chronic type found in well-nourished individuals, or those cases who have no fever when at rest, but have a rise in temperature on slight exertion. But even among these types only an occasional case will be found in whom tuberculin can be credited with lowering of fever.

If fever is considered a spontaneous tuberculin reaction the injection of more tuberculin would seem to be contraindicated. The favorable results seen in some febrile patients taking tuberculin is explained by Shali[14] to be due to the sudden variation in the concentration of the poison in the organism. The injection causes a favorable anti-action, an anti-action which does not result from the more uniform absorption in the natural course of the disease.

Whatever the theoretical grounds for and against its use in febrile cases, tuberculin doubtless has an antipyretic effect in some patients. Phillippi[15] reports that in ninety cases of all stages who had had fever for an average period of five and one-half months before the commencement of specific treatment sixty-five became afebrile with tuberculin. The average time required was from twenty-four to fifty-six days, depending upon the stage of the disease.

On the other hand, Bardswell[16] in his recent report says that he has failed to obtain any conclusive evidence of the antipyretic value of tuberculin. He adds that "tuberculin can often be given to febrile cases without the production of reactions, but even if such disturbances are avoided, no beneficial effects have so far been noticed."

Thus one is forced to the conclusion that tuberculin given to febrile cases in extremely small doses (.0000001 gm. to .00000000001 gm.) may do no harm and may possibly work the desired effect. Such treatment, however, is fraught with danger.

Hydrotherapy is one of the oldest remedies for allaying fever. Its usefulness is so well known that no extended comment is needed here. Often a little alcohol, or vinegar, added to the water in the proportion of one to four and used as a sponge bath

will be found useful. An alcohol rub is of great service, as the rapid evaporation cools the skin. A cold-water coil, or an ice bag over the heart is soothing to many patients.

Ice rubs, cold packs, or cold spinal douches, are vigorous measures and should be used with caution in the tuberculous. Any hydrotherapeutic measure that excites or fatigues the patient may prove more harmful than helpful.

Dietetic.—Sahli[4] recommends a short "fasting cure" when patients are running a high fever. He believes that fever more often subsides with a scanty diet than with a free one; that in fever there is incomplete digestion, and that a rich supply of food adds new toxic factors to the question, and perhaps promotes the direct absorption of foreign protein and bacteria from the intestines. On the other hand, a diminished food supply acts as an antipyretic in decreasing the production of heat.

In acute febrile attacks a limited diet, such as milk and the whites of eggs, is given, and with the lowering of temperature a gradual return to solid food. A slight temporary loss in weight during such an attack is of less moment than the digestive disturbances caused by forced feeding.

With the chronic type of fever as much solid food should be given as is compatible with the digestive powers of the patient. Fever rarely abates in a patient losing weight.

Medicinal.—The artificial reduction of fever by drugs is a questionable procedure. If fever is a part of the defensive mechanism of the body, on theoretical grounds, the use of drugs as antipyretics would be contraindicated. However, with uncontrolled high fever sapping the strength of the patient, and producing distressing effects upon mind and body, we are justified in making a trial with them.

Unfortunately, results are not uniform. If an antipyretic effect is obtained this is usually lost immediately on stopping the drug. Very frequently the unpleasant after effects of the antipyretic are of more discomfort than the fever itself. Very rarely is a permanent lowering of the temperature seen after the administration of a drug.

Drugs which have a direct effect upon fever are the coal-tar and wood-tar derivatives. Their exact action upon the heat-regulating mechanism is not known, but following their ingestion decomposition products are formed in the tissues, and at the same time fever falls.[17]

The various members of this group differ chiefly from each other in the rapidity with which these products are formed. A rapid formation leads to blood changes and collapse, while the antipyretic effect passes off quickly. Those drugs are found the most satisfactory in which this decomposition proceeds gradually, so that the temperature falls slowly and remains low for a longer time. A partial list of these drugs or their derivatives includes antipyrine, antifebrine or acetanilide, phenacetine, analgine, thalline, salophen, salicylic acid, salicin, salol, aspirin, and pyramidon.

Probably the drugs used most frequently to-day for the reducton of fever in phthisis are pyramidon and aspirin. Both these preparations have held their own against all the other drugs which have flooded the market. Pyramidon is best given in small doses (2 to 5 grains) in a glass of water to be sipped over a period of three or four hours before the usual rise of temperature. The dose may be repeated in an hour. Aspirin is usually given in 5-grain doses, but frequently 2 to 3 grains will be enough to cause profuse sweating.

There are two points to be remembered in the administration of antipyretics. First, individuals vary in their susceptibility toward them, and second, patients using these drugs for any length of time often acquire a tolerance toward them.

The disagreeable results attendant upon the use of antipyretics are sweating, chills, and depression. When the fall of temperature is rapid, sweating is very likely to occur, and the following rise of fever causes chills or chilliness. During the day after the use of these drugs there is often a marked mental and bodily depression.

New preparations aimed to produce antipyretic effects without the attending disagreeable symptoms are being added to the list year by year. A few of these newer drugs are: Melubrin, a substitute for aspirin, said to have a longer antipyretic effect; aspirin-calcium, which contains 10 per cent. of calcium, and is said to be better borne than aspirin; hydropyrin grifa, a watery solution of the lithium salt of acetyl-salicylic acid (aspirin)—Neivling[5] recommends it combined with arsenious acid in the chronic fevers of phthisis; tropfenform, a preparation from ichthyol; and iodglidine, derived from iodine.

Good results are said to follow the injection (either intramuscular or intravenous) of colloidal copper (electrocuprol). Thirty-eight cases reported by Damask[19] became permanently afebrile after three to twelve injections. Subcutaneous injections of 20 per cent. camphor oil twice a day have been recommended by Weihrauch,[20] 20 per cent. of his two hundred and forty-six cases so treated showed complete or partial reduction of fever after ten to forty injections. G. Schroeder[21] was unable to convince himself of the usefulness of this remedy for fever.

Hartley[22] has had success in treating febrile tuberculous cases without a luetic history with neosalvarsan. His sixteen cases all showed a defervescence after from one to three injections. No severe reactions occurred, although some patients were in a far advanced stage. He recommends that this form of treatment be given a more extended trial among the febrile tuberculous.

Summary.—The points to be emphasized in the therapy of fever in tuberculosis are briefly these: First and foremost, absolute rest in bed, preferably out of doors; artificial pneumothorax in selected cases; a trial with autogenous vaccines, especially when there is copious purulent expectoration; the cautious use, if at all, of tuberculin, and then only after other measures have failed; hydrotherapeutic measures suited to the condition and comfort of the patient; an ample diet, but not necessarily "forced feeding"; and the judicious use of medicinal antipyretics.

GANGRENE WITHOUT ORGANIC VASCULAR DISEASE.

By LEO BUERGER, M.D.

NEW YORK.

ASSOCIATE ATTENDING SURGEON AND ASSOCIATE IN SURGICAL PATHOLOGY, MOUNT SINAI HOSPITAL; ATTENDING SURGEON, HAR MORIAH HOSPITAL; INSTRUCTOR IN CLINICAL SURGERY, COLUMBIA UNIVERSITY.

AND

ADELE OPPENHEIMER, M.A.,

NEW YORK.

FORMERLY VOLUNTEER ASSISTANT, PATHOLOGICAL DEPARTMENT, MOUNT SINAI HOSPITAL.

THERE are still many clinicians who are of the opinion that gangrene of the extremities must depend upon some organic derangement of the patency of the arteries or veins, regarding those scant reports of Raynaud's disease, in which changes in the vessels have been found, as being irrefutable testimony in favor of their own view. An analysis of such references in the literature has convinced us that no distinct causal relationship between the vascular lesions and the symptoms has been definitely established in any of the reported cases. Furthermore, when in the course of our studies on arterial disease we had the good fortune to obtain amputated material from two cases of gangrene *in which all the vessels were pulsating*, an opportunity was afforded us to prove conclusively that *even extensive, spontaneous gangrene can occur without organic vascular disease.*

In previous publications* it was held by one of us that it is possible by clinical and pathological attributes to separate two great classes of cases in which vasomotor and trophic disturbances of the extremities dominate the clinical picture, those dependent on and those independent of vascular disease.

In order that all doubt may be dispelled as to the possibility of the occurrence of gangrene in the absence of vascular disease, it may be of some value to report briefly the histories of our two cases and also to give a resumé of the results of our pathological studies.

CASE I.—*Sensory and vasomotor phenomena of both lower extremities, gangrene of small extent with pulsating and normal vessels.* M. R., male, Russian Hebrew, 40 years of age, was first examined by us on November 24th, 1908, at the Mount Sinai Hospital. As far as can be elicited, there are no nervous stigmata; habits good, very little alcohol, smoking moderate. Some 6 years ago he remembers having had some "trouble" with both feet. There were periods of weeks and months during which the toes of both feet became exceedingly painful, the big toes being first affected, followed by successive involvement of each and every toe of both feet. He is not certain that the toes were discolored, but believes that they had a tendency to become blue. There was no pain in the leg and foot on walking. These symptoms would pass off after 2 or 3 months, and did not reappear for almost 9 months. He distinctly remembers a severe recurrence after this interval, but the relapse was not of as long duration as the initial attack. He has been free from all symptoms for almost 4 years.

In August 1906, he was first attacked with severe pain in the middle toe of the left foot. The toe became discolored, intensely blue and slightly swollen. Gangrene set in within 3 weeks and in September the toe required amputation. There had been no trouble in walking or any ache whatsoever, nor can the patient think of any cause for the affection, such as injury, exposure, etc.

In June, 1907, there was pain in the toes of the right foot, the fourth toe soon becoming blackish, and ulcer resulting after the separation of some mortified skin.

In September 1908, the middle toe of the right foot and the little toe of the left foot developed similar manifestations with small areas of gangrene.

Examination, November 24th, 1908.—Left leg: The third toe has been amputated at the first interphalangeal joint. The fifth toe is cyanotic over its distal half. Otherwise the color of the foot is normal. *All the palpable vessels of the foot and leg, the dorsalis pedis, posterior tibial, the femoral and the popliteal pulsate strongly.* Right leg: There is marked cyanosis of all the toes, particularly of the third toe even in the horizontal position. In the pendent position, the cyanosis gradually deepens, but absolutely no evidence of rubor or erythromelia can be elicited. In the horizontal position, the tips of the third, fourth and fifth toes are purple, but apparently less so than when examined some two weeks ago. There is a superficial patch of gangrene over the third toe, and the fifth toe shows the deepest blue discoloration. *All the vessels pulsate, the dorsalis pedis, posterior tibial, popliteal and femoral.* In the elevated position, it is difficult to determine whether ischemia is present or not. At any rate, it is not sufficiently marked to be diagnostic. In the pendent position, the right leg becomes more blue, the veins stand out very prominently and, at times, one can see a certain amount of rubor which is not typical of thrombo-angiitis obliterans. The same phenomena are present when the left leg is examined in this position; the pain becomes more marked, to such an extent that the patient cries for relief wishing to bring the foot back to the horizontal position. Sensation is practically normal over both feet and even the gangrenous toe has sensation, except over the mortified area. Nerve status, negative (no evidence of syringomyelia). Thus the symptom-complex is mainly characterized by *cyanosis* of the toes and foot, *gangrene* of slight extent with *pulsation of all the palpable vessels.*

On December 29th, 1908, the patient was again admitted to the Mount Sinai Hospital. He says that for more than a month the little toe of the left foot has troubled him, the bluish color persisting, till gangrene finally set in.

Physical examination shows dry gangrene of the distal half of the little toe of the left foot. Now, too, the striking signs are the pulsation of the vessels, cyanosis and gangrene.

January 4th, the little toe was disarticulated and within a month the wound was healed.

In brief, we are dealing here with a case in which, after a prodromal period of attacks of sensory disturbances in the lower extremities, there supervened paroxysms in which sensory and vasomotor disturbances made their appearance. These in their turn gave way to dry gangrene, the toes of both feet being affected almost symmetrically. The absence of the typical ischemia, of erythromelia and of any evidence of obliteration of the vessels, excludes the diagnosis of thrombo-angiitis obliterans; we may, therefore, assume that we have here, either a case of atypical Raynaud's disease or of so-called "acro-asphyxia."

CASE II.—*Paresthesiæ, chronic cyanosis, and pain terminating in gangrene; all palpable vessels pulsating.*—M. S., 50 years of age, male, Russian Hebrew, admitted to the Mount Sinai Hospital, February 13th, 1909, traveling salesman; in this country four years. Habits good, smokes ten cigarettes daily, married, four children, denies lues. He thinks that about 13 years ago, he had symptoms in the right hand similar to those that now affect his left leg. The finger tips

*Buerger: *Am. Jour. Med. Sc.*, Oct., 1908, and Jan., 1910.

were blue and cold, and there was a feeling of "pins and needles," with occasional pain, lasting for almost two months.

About 6 months ago his right leg began to trouble him, and the second toe became very blue, but the symptoms all disappeared upon internal medication. Three months ago he began to experience peculiar sensations in the toes of the left foot, and the third and fourth toes became very blue. In addition to the pain and cyanosis, there were peculiar sensations in the toes and in the ball of the foot, as if they were pricked by needles. As time went on, these pains increased so that they finally became almost unbearable in the pendent position of the leg. As for the general symptoms, he complains of frequent dizziness, and attacks in which spots appear before the eyes.

Physical examination: The patient is a well nourished male; heart negative; radial pulse somewhat thickened. Left leg: The third and the fourth toes are distinctly bluish, the foot is cold; *all the palpable vessels are found to pulsate distinctly.* Right leg: There is slight cyanosis in the pendent position. Wassermann reaction negative; blood varying between 150 and 175 mm. Nerve status; no evidence of any organic nerve lesion can be detected on complete examination of nerve status (D. I. Strauss).

Examination, February 24: Left foot: Cyanosis of the left foot has considerably deepened in the horizontal position; the third, fourth and fifth toes are very blue, and on the plantar aspect suggest that these are the seat of the impending gangrene. *The dorsalis pedis, posterior tibial, popliteal and femoral arteries pulsate strongly.* There is slight edema of the forepart of the foot.

March 4, 1909: Now the third toe of the left foot over its distal phalanx is distinctly gangrenous, the foot and ankle are very edematous, although all the vessels can be felt pulsating. There is no marked erythromyelia, no marked ischemia in the elevated position.

March 7: The second and third toes of the left foot are now completely gangrenous; the fourth toe shows a patch of superficial gangrene over its plantar aspect; the big toe is slightly cyanotic, but shows no evidence of gangrene. The edema of the foot is increasing considerably.

In short, within a period of four months, the symptoms being cyanosis and pain in the left foot, there finally developed gangrene of three toes. Because edema was rapidly increasing over the foot and leg, and the gangrene bid fair to extend rapidly, and because of the intense, almost unbearable pain, it was decided to amputate, so that on March 11 the leg was ablated through the upper fourth by Dr. F. Oppenheimer. *The larger vessels were found patent* and required ligation. None of the usual appearances so characteristic of the vessels in thrombo-angiitis obliterans were found, and no evidences of thrombosis discovered at the point of section.

On the following day, secondary hemorrhage occurred. The patient was taken to the operating room and the vessels caught and tied.

On March 24, 1909, because of sloughing of the skin and absence of any tendency to heal, reamputation was done, after which the wound healed slowly, the patient being discharged on May 18, 1909.

Summarizing the important features of this interesting case, we may say that in a patient in whom some thirteen years previously there had been a distinct history of vasomotor phenomena in the upper extremities, and in whom, some six months ago, the right lower extremity also seemed to have been involved in a similar way, there finally developed the following symptom-complex in the left leg: paresthesiæ, pain and asphyxia or cyanosis of the left foot. After a period of four months, in which the pain became more and more severe, the cyanosis involving three of the toes deepened, finally terminating in gangrene. All of the vessels that can ordinarily be palpated were found distinctly pulsating and at operation proved to be patent at the point of ablation.

Pathological Examination.—It was the material from the second case which was particularly valuable for our pathological studies. In Case 1, we were only able to obtain the little toe for examination; in Case 2, however, the foot and lower two-thirds of the leg were carefully dissected and practically all of the larger arteries, veins and nerves preserved for microscopic examination, as well as the tissue of four of the toes. A thorough study of the larger nerves in Case 2, with the usual histological methods, was included in the investigation. For our purposes here it will suffice to record simply a brief summary of the pathological findings, reserving a detailed account for a future publication on the subject of gangrene.

In addition to the vessels of the toe in Case 1, the following arteries and their accompanying veins were completely dissected out in continuity in Case II, and a larger series of microscopic sections made: the posterior tibial, anterior tibial, the plantar arteries, dorsalis pedis, their venæ comites, and the internal saphenous vein through their course, and all of the tissue save the bone of the second, third, fourth, and fifth toes.

Except for slight thickening of the walls of the veins and arteries in a few places, and an occasional sign of the earliest atherosclerotic changes, the vessels were practically negative throughout; nowhere were they occluded.*

As for the nerves, the following were examined: the internal and external plantar, the anterior tibial, the posterior tibial, and branches of the peroneal nerve. In none of these could degeneration be detected. The Marchi and Bielschowsky were the methods employed in searching for degeneration.

In short, there were neither lesions in the nerves nor in the arteries and veins that were in any way related, or could be held responsible for the gangrenous process in either the first or second case.

If we call to mind the various affections of the extremities in which sensory, vasomotor, and trophic disturbances co-exist in varying syndromes, we have, on the one hand, those in which the clinical manifestations depend on occluded arteries, on arteries and veins, and on the other hand, those in which neither organic vascular disease nor organic nerve lesion can satisfactorily explain the phenomena. In the former group we include the disease "thrombo-angiitis obliterans" and the atherosclerotic and endarteritic affections of the vessels of the extremities. To the latter group belong erythromelalgia, Raynaud's disease, gangrene, chronic acroasphyxia, scleroderma, sclerodactyly, and multiple neurotic gangrene, etc. All of these may terminate in a gangrenous process that arises spontaneously, without the aid of external physical agents, such as trauma, or of chemical influences.

If we analyze the histories of our two cases we at once realize that it is to the second group that our patients belong, the differential diagnosis in both resting between Raynaud's disease and chronic acroasphyxia. Whereas the first case seems more closely related to the Raynaud affection, the more progressive and continuous nature of the cyanosis and the absence of paroxysms would tend to characterize the second case as one of the group "acroasphyxia chronica."

Conclusion—It has, therefore, been definitely shown by our pathological investigations of the vessels and nerves in one case of gangrene of the lower

*Only few arteries leading into some of the gangrenous areas showed recent thrombosis, doubtless as a sequence of the mortifying process. Some interesting observations were made on the minute vessels in the subcutaneous tissues. Marked proliferation of capilaries was noted in places. These, however, did not seem to be of significance and we, therefore, reserve a discussion of the finer histological points for future publications.

extremity, and by clinical observations of two cases, that spontaneous gangrene can occur in the presence of patent vessels and of peripheral nerves in which no significant pathological alterations can be detected.

INTESTINAL TOXEMIA AND DIABETES.

By ALFRED C. CROFTAN, M.D.,

CHICAGO, ILL.

REDUCED carbohydrate tolerance (*i.e.* glycosuria following the administration of 100 to 150 grams of dextrose when the stomach is empty) will often be found in patients presenting the manifold clinical picture to be presently described; this is associated with the excretion of abnormally large amounts of aromatic bodies in the urine, viz., chiefly aromatic sulphates, with indican, in quantities over 20 mg. per diem, as their main representative, and aromatic (conjugate) glycuronates. The latter reduce Fehling's solution and may lead to confusion with true glycosuria.*

As a rule all these bodies indicate excessive intestinal putrefaction with absorption of abnormal aromatic cleavage products of albumin; the latter being produced in such excess that after saturation of the available sulphuric acid to form aromatic sulphates (indican, etc.) a surplus calls for saturation with glycuronic acid, causing the elimination in the urine of aromatic glycuronates. This in itself constitutes a mild interference with the normal carbohydrate metabolism, for glycuronic acid is a product of the incomplete oxidation of dextrose. Hence, even in the absence of dextrose from the urine, the excretion of glycuronates may constitute a diabetic, or "pre-diabetic," phenomenon. Combined with dextrose glycuronates are often found in the urine in fully developed diabetes.

The subjective complaints of the patients are essentially dyspeptic (dystryptic); these are symptoms in the region of the upper abdomen without, as a rule, determinable evidence of organic lesions about the stomach, bowel, liver, or pancreas, even when the abdomen is opened, as is so frequently done on suspicion. The difficulties in the beginning, at least, are purely functional in character. Constipation is the rule, now and then alternating with diarrhea, the latter the result of chemical and mechanical irritation of the sigmoid and rectum, as manifested by the appearance of mucus, occasionally a little blood in, or rather on, the stools. Vague aches and pains all over the body (possibly a mild toxic polyneuritis) are very common. Practically all of these patients are depressed and chronically fatigued. Hence they are frequently classified as neurasthenics or, on account of the fleeting pains in muscles and joints, as rheumatics, or, on account of the scanty, concentrated urine, with resulting abundant sediment, as uric acid cases.

Very characteristic are disturbances involving the sympathetic system with vasomotor instability manifesting itself chiefly in poor capillary circulation, hyperhidrosis with cold extremities, occasionally dermography and hives. Vagus irritation becomes manifest in arrhythmia, fluttering of the heart, palpitation, all very disagreeable to the patient, but not interfering with active exercise; in fact, usually disappearing upon physical exertion. Now and then one encounters very troublesome visual disturbances that are characterized by their unstable character, so that attempts at refractive correction remain quite unsatisfactory. Often the pupils are dilated and respond only sluggishly to light. Roaring in the ears is a common symptom without discoverable local causes. Headache, especially of the migrainous type, is occasionally observed.

In all cases presenting the above syndrome together with the urinary findings described, I have made it a rule to make tolerance tests for dextrose and I find marked degrees of tolerance reduction in a large proportion of these patients. A normal subject should excrete no dextrose in the urine, after the ingestion of from 100 to 150 grams of dextrose when the stomach is empty. Nearly all of these patients do. In some of them even intolerance to other carbohydrate foods can be discovered.

The trouble no doubt lies primarily in the upper intestine, for the most important early steps in the carbohydrate metabolism are carried out in this region and in the large digestive glands tributary thereto. Broadly speaking the picture is that of a chronic intoxication, presumably the result of incorrect, disturbed degradation, especially of the food albumins, aided by the decomposing action of putrefactive bacteria upon abnormal albumin fragments.

The exact nature of the poisons generated in this way remains quite uncertain, although naturally nearly every cleavage product found in the intestine has been incriminated; nor has it even in fact been demonstrated with accuracy that poisons circulate at all. In view of the fact, however, that the symptoms produced in these cases markedly resemble the manifestations of certain alkaloids that are intensely toxic, so that they can produce very harmful effects in almost incredibly small doses that assuredly would evade detection by chemical means; in view of the fact that biologic means of detection are as yet inadequate, particularly as we are in all probability dealing with putrefactive products of albuminous molecules that differ only slightly from the normal fragments (it should be remembered that the nearer cleavage products remain in their composition to the original molecule, the more toxic they appear to be) it need not surprise us that we cannot specify certain definite chemical individuals as the offending malefactors. We are quite justified, however, in postulating their existence from their manifestations.

The development of alimentary glycosuria (reduced tolerance) and later diabetes in these cases is presumably the result of prolonged injury by these poisons to the liver and to the pancreas, the liver being continuously flooded with the toxins as they pour into the portal system, the pancreas being in-

*These glycuronic acid compounds often produce in the absence of urinary dextrose simply a browning of Fehling's solution, a "delayed Fehling reaction." The differentiation between glycuronic compounds and dextrose is not always easy. Whereas the free acid is dextrorotary, its aromatic compounds turn the plane of polarized light to the left. Hence urines containing no dextrose but slightly reducing Fehling's solution should, if they contain aromatic glycuronates be levorotary. In order to demonstrate positively the presence of glycuronic acid, the latter must be liberated from its compounds by boiling with dilute sulphuric acid. The orcin test is then made. If it is positive, corroborative evidence can be secured spectroscopically. If urine containing dextrose remains levorotary after removal of the dextrose by fermentation, beta oxybutyric acid, or aromatic glycuronates may cause this levorotation. If, however, the urine after fermentation still reduces Fehling's or Nylander's solution and gives a positive orcin reaction, then the presence of glycuronic acid compounds is demonstrated.

volved either directly by ascending infection through its ducts or indirectly via the liver; the sequence cholangitis, cholelithiasis, chronic pancreatitis being notoriously common. Injury either to the parenchyma of the liver, to the duodenal wall, or the pancreas can produce diabetes.

The treatment of these conditions can be discussed under three heads, dietetic, medicinal, surgical.

To place these patients at once upon the discovery of a reducing urine on an "antidiabetic" diet is, of course, bad practice. If the reducing body is glycuronic acid then such a meat-fat diet is actually harmful and an increase of the glycuronates and of the other aromatic bodies will be promptly noticed, together with an aggravation of the symptoms. For the main exogenic sources of these aromatic radicles are the food albumins; to increase the latter far above normal rations, therefore, of necessity increases the source of poison.

If the urine contains no dextrose or small quantities of dextrose, associated with large quantities of aromatic bodies (viz., indican in quantities of 30 to 100 mg. a day and glycuronates, *vide supra*) then the diet should primarily be arranged in such a way that the aromatic bodies become reduced. even though dextrose excretion in the beginning supervenes or, if it is already present, remains at the same level or even slightly increases. To accomplish this the diet for a period of days should consist of vegetables, fruits, coarse cereals, bran breads, nuts, milk diluted with lime-water, buttermilk similarly diluted, an abundance of fat in the form of cream, butter, olive oil on salad dressings, and a little bacon, with the minimum of meat, fish, poultry, eggs, and all preparations made from them. All alcoholic beverages and malted liquors and all spices and condiments are forbidden. As a rule all actual sweets are forbidden at first; in some cases it is permissible, heterodox as this may seem, to feed these patients for 24 or 48 hours on a sugar solution exclusively, preceded by a thorough purgation; this reduces the toxemia more rapidly than any other measure, short of actual starvation, and gives the upper bowel region a "digestive rest" that is often beneficial, and in favorable cases accelerates the restoration of normal function.

Such a diet produces a bulky stool, the abundant cellulose undergoing slow gaseous fermentation and rendering the stools fluffy, the fat producing a soapy soft stool that is readily evacuated. It will often be found that on such a diet, even though it incorporates abundant carbohydrate, the sugar excretion will generally remain stationary, occasionally decrease and often disappear, whereas glycosuria promptly recurs as soon as animal proteins are added to the diet. Patients can, of course, maintain their nutrition for an indefinite period on a vegetarian-farinaceus-fat-milk regime of this kind; it is usually unnecessary, however, to maintain this schedule indefinitely, so that after a few weeks meat, fish, poultry, eggs can be gradually added. If they are well tolerated (using the excretion of aromatic sulphates, etc., as an index) while the dextrosuria still persists, then the amount of carbohydrate ration should be gradually reduced, occasional tolerance tests made for control, and in this way the tolerance raised as in any other case of mild diabetes and according to all the well known rules relating to the maintenance of the general nutrition of this class of patients. A one-sided diet is by all means to be decried as well as any routine form of treatment. Individualization is necessary.

Medicinally something can be accomplished in several directions; either, first, by way of a substitution therapy, normal digestive ingredients of the intestine may be supplied, or the secretion of the digestive glands may be artificially stimulated, or, second, certain drugs may be administered that can hold the activity of putrefactive bacteria in check, so-called intestinal antiseptics.

To the first group of remedies belong pancreas and bile preparations. Dried pancreas preparations usually contain an indefinite quantity of inactive material so that it becomes very difficult to standardize their amylolytic or tryptic powers. Moreover, toxic albuminoids are frequently present, the result either of proteolysis occurring during the process of preparation, or of bacterial contamination. Much to be preferred are glycerin extracts of pancreas prepared aseptically.

Of bile preparations the bile-acid salts are in all probability the only bile ingredients that become operative in the upper intestine; as it is possible to isolate them without difficulty from bile, these bile-acid salts, chief among them sodium glycocholate, should by all means be employed in place of the preparations of whole bile. The mode of action of the bile acids is manifold, and has been fully described elsewhere.* Not only do they furnish an ingredient necessary for the proper conduct of digestion in the upper intestinal tract, but they also constitute one of the few real cholagogues we possess and incidentally, both directly and indirectly, operate to reduce bacterial activity; hence they can also be included in the group of intestinal antiseptics.

Sapo medicatus is another valuable cholagogue and is claimed to stimulate the secretion of the pancreas (Felig). The sodium salt of oleic and margarinic acid being normal to the upper intestine renders the remedy essentially a physiological stimulant to hepatic and pancreatic activity.

These remedies should be administered in combination with an alkali, preferably sodium bicarbonate, to be effective. Chologestin may be used in mildly glycosuric cases; it is sugar free and contains sodium glycocholate, a glycerole of pancreas, and sodium bicarbonate in a palatable vehicle.

Salicylic acid and its salts are generally included among the intestinal antiseptics, so called, but I have not found it particularly effective in reducing the urinary excretion of aromatic substances. Hexamethylenamine occasionally produces a good result. The metallic antiseptics are dangerous; organic peroxides, lactic acid bacilli, I have never been able to form a real opinion about.

While the difficulty in these cases lies in the upper intestinal tract, still it is useful to promote thorough cleansing of the large intestine frequently by enemata and by the use of saline laxatives. This should be done systematically. Violent purgatives or carthartics and calomel should not, however, be administered to these cases. Gastric lavage, provided there is stagnation of stomach contents, as the result of mechanical obstruction or of motor insufficiency, may, of course, aid in reducing the toxemia; when gastric motility is normal this measure is, at least, superfluous.

*Croftan: "Some Experiments on the Intermediary Circulation of the Bile Acids," *Am. Journ. Med. Sciences*, January, 1902; "The Bile Acids as a Remedy," New York *Medical Journ.*, April 21, 1906.

In cases presenting evidence of gallstone disease, associated with glycosuria and profuse urinary excretion of aromatic bodies, the diagnosis of chronic pancreatitis must be considered. Cholelithiasis and pancreatitis are not infrequently associated and removal of the gallstones or relief of the cholangitis occasionally cure the pancreatitis; in more advanced cases incision of the pancreas is indicated and is occasionally effective. Special functional tests for pancreatitis should precede such an inroad.* And it should be remembered that the presence of sugar in the urine in these cases must in no way be considered a counter-indication to surgery. Provided the diagnosis is correct, these glycosurias disappear. Chloroform should never be used as an anesthetic in this type of patients; for alarming degrees of acidosis with serious damage to the liver parenchyma have been known to result from its use.

25 East Washington Street.

EHRLICH'S ALDEHYDE REACTION FOR UROBILIN.†

By SAMUEL BERKOWITZ, M.D.,

NEW YORK.

Urobilin, first described in the urine by Jaffé,[1] has been the source of extensive discussion among clinicians and laboratory workers. Reports on the biological and chemical origin, methods of recognition and clinical significance vary with the clinics and laboratories from which they appear. Some laud its value, other condemn it—the enthusiasts are, however, in the majority.

That urobilin is derived from hemoglobin is beyond reasonable doubt, but it is believed by some that the bile pigments represent intermediate changes in this transition. Hoppe-Seyler[2] was able to prove conclusively that hemoglobin with the aid of strong reducing agents could be changed to urobilinogen and the latter to urobilin by exposure to daylight. This Disqué[3] proved was due to oxidation. Moreover, Nencki and Zaleski[4] showed that hematin was also an intermediary stage in this process.

Numerous theories, many supported by experimental data, and a few which do not stand such close scrutiny, are offered for the biological explanation of the appearance of this substance in the urine. Those worthy of discussion may be thus grouped (1) Hepatogenous, (2) Enterogenous, (3) Renal, (4) Hematogenous, (5) Histogenous, and (6) Hepatoenterogenous.

Hepatogenous Theory.—Fishler,[5] in support of the hepatogenous theory, produced biliary fistulæ in dogs and drained the bile externally. He injected amyl alcohol and phosphorus into the gall bladder. The liver showed marked pathological changes and urobilin appeared in the urine. Berghausen[6] demonstrated that in order to induce urobilinuria in these cases it was necessary that the poisons act slowly. Under circumstances in which the poisons act rapidly death ensues before the changes take place; and the urine in the bladder is, therefore, negative. Hayem[7] classifies the hepatogenous type of urobilinuria into absolute and relative—the former, if the pathological changes occur in the liver, and the latter when extraordinary quantities of blood pigment are brought to the liver as occurs in the blood dyscrasias associated with the destruction of the red cells, thus exaggerating the normal functions.

Enterogenous Theory.—According to Hildebrandt[8] urobilinogen and urobilin originate from bilirubin by bacterial decomposition which occurs only in the intestines. In order to show the importance of the intestines in the mechanism of the formation of urobilin, Moller[9] mentions a case of marked jaundice due to complete obstruction of the common duct by a malignant growth at the ampulla of Vater with metastases in the liver and a negative urobilinuria. He maintains that the absence of bile in the gut signifies an absence of urobilinogen and urobilin in the urine. Eustice[11] also mentions an absence of the reaction with icterus due to complete obstruction of the common duct and notes that on the return of the bile flow to the intestinal tract the reaction is again positive. Müller,[12] the earliest observer on the absence of urobilin in the urine when the common duct is closed, gave such a patient bile by the stomach tube and immediately the urobilin reaction was positive. Since in the early life of the newborn the intestinal bacteria are few in number urobilinuria rarely occurs during this period. Kimuria[10] cites a series of cases of marked diarrhea in which the fecal contents passed through the intestines so quickly that the bacteria were not given ample time to exert their deoxidizing influences. The urines gave negative tests. In connection with this discussion may be mentioned sixteen cases of urobilinuria which were thought to be due to a patent ductus venosus, *i. e.* the blood of the intestines went directly into the general circulation without entering the liver. This series occurred in the same family.[13] An attempt[6] made to prove Neubauer's contention that ligation of the common duct gave negative reactions was successful on two rabbits.

Renal Theory.—Gilbert and Herscher[14] argue that the bile pigments circulating in the blood reach the kidneys and are there transformed into urobilin. Jaksch[15] upholds the above contention and considers all cases of urobilinuria as having been preceded by a urobilinemia. To disprove this theory Fishler[5] perfused the kidney with urobilin, but failed to get a positive urobilinuria.

Hematogenous Theory.[16]—Marked urobilinuria is associated with severe malaria, paroxysmal hemoglobinuria, scurvy, lead poisoning, and pernicious anemia, but the underlying pathological basis for the findings is open for further observation. Still the intimate relation between hematin and urobilin was made clear by Nencki and Zaleski.[4]

Histogenous Theory.[16]—In jaundice large amounts of bilirubin are deposited in the tissues and are subjected to local changes which lead to the formation of urobilin and its excretion in the urine.

Hepatoenterogenous Theory of Friedrich von Müller.—In the production of urobilinogenuria and urobilinuria pathological changes are necessary in the liver while the intestines must be functionating normally. The bacteria will thus deoxidize the bile pigments and allow their absorption into the portal circulation so that if the liver is overwhelmed with work the urobilinogen and the urobilin will pass into the general circulation unchanged.

As previously noted, Moller states that unless bile passes into the intestines, bilirubin cannot be changed into urobilinogen and urobilin. On re-

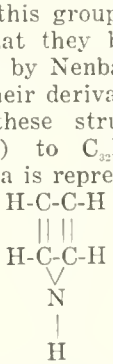
*Croftan: "Pancreatic Diabetes and Its Relation to Gallstones," *Surgery, Gynecology, and Obstetrics*, December, 1908.

†From the Chemical Laboratory, Beth Israel Hospital, New York.

turning to the liver *via* the portal circulation the latter are again transformed into bilirubin if the liver functionates normally. In cases of inefficiency of the liver they pass into the general circulation and are later recognized in the urine. The interrelation between urobilinogen and urobilin is so intimate that the term urobilin will be used to indicate both.

In alcoholic cirrhosis Fishler[17] holds that it is absolutely necessary to have a positive urobilin reaction in the urine, otherwise the clinical diagnosis is incorrect.

The chemistry of this group of substances leads to the conclusion that they belong to the pyrrol derivatives as shown by Nenbauer,[18] who disproved Nencki's theory of their derivation from indol. He also showed that these structures range from $C_4H_{11}N$ (hemopyrrol) to $C_{32}H_{40}N_4O_7$ (urobilin). Their general formula is represented by



The five methods of examination for the presence of urobilin in the urine are:[19]

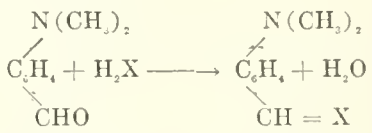
1. *Salting Out with Ammonium Sulphate.*—This method is advocated by such authorities as Hoppe-Seyler,[20] Viglezio,[21] Ladage,[22] and Charnas.[23]

2. *The Spectroscopic Method.*—The spectroscopic method is recommended by Gerhart,[24] Beck,[25] Saillet,[26] Conner and Roper,[16] Auché,[27] Simpson,[21] Hayem,[7] Deniqué,[28] Hildebrant,[29] Zoja,[30] and Charnas.[23] This method depends upon a characteristic spectroscopic band between b and F produced by the filtrate after adding an equal amount of a 10 per cent. alcoholic solution of zinc acetate.

3. *The Fluorescence Method.*—The filtrate in the preceding method shows a typical fluorescence.

4. *The Colorimetric Method with Copper Sulphate.*—This test is made by adding copper sulphate to urobilin solutions. A violet color denotes a positive reaction.

5. *The Colorimetric Method with Ehrlich's Aldehyde Solution.*—This color reaction depends upon the appearance of a pink to a red color on adding an acid solution of para-dimethylaminobenzaldehyde* to urobilin urines. The clinical significance of the presence or absence of the urobilin group and if present the relation of small and large amounts by this method arouses our attention. Extensive investigations have been recorded since the discovery of this substance in the blood, urine, and bile. Of the newer methods the Ehrlich aldehyde reaction is the most recent. About a decade ago Ehrlich accidentally discovered that a hydrochloric acid solution of this drug gave a pink color on addition to some urines and not to others. This was later determined to be due to pyrrol derivatives.[18] That the above reaction occurs according to the following formula in which the aldehyde combines with a methylene or amido group of a still unknown constituent has also been considered. "X" represents the unknown quantity.



The urine analyses with the aldehyde reaction have thus far been limited to a few classes of cases and with a view of examining a large number of normal and abnormal urines of every description was the present problem undertaken. Many of the findings coincide with those of previous observers, many other, however, show surprising results.

The technique of the reaction is as follows: A few drops to one c.c. of a 2 per cent. solution of para-dimethylaminobenzaldehyde are added to five c.c. of urine. A positive reaction consists of a pink or reddish color imparted to the solution which intensifies on standing. Dark amber discolorations appear slightly reddish on looking through the column of the fluid and become more marked on heating in a flame for a few seconds. In some instances shaking the mixture with chloroform produces a pink color in the chloroform which is also considered a positive test. A light green color after adding the reagent is always negative.

Normal Cases.—The urines of twelve men were used for this series of tests and three to four specimens in each instance, making a total of about forty analyses. In each urine a deep red color appeared as soon as the reagent was added showing what would be considered a heavy urobilin reaction. A number of careful observers were only able to find traces and others no urobilin in normal urines. However, all did not use the aldehyde test. That the above urines were otherwise normal is indisputable; they were recently examined. Braun[32] considers urobilinuria only pathological when in large amounts. Conner and Roper[16] hold that no urobilin occurs in freshly voided urine. Their researches do not lay particular stress on the above test since they were more interested in other methods especially in their relation to blood serum examina-

−Negative reaction.

tions. Wilbur and Addis[19] state that normal urine gives a positive reaction for only a very small quantity. Baar[33] made the same observation using freshly passed urine. In summarizing his findings Simon[31] mentions that the presence of urobilin in the urine is not normal and thinks it necessary to have the urines within twelve hours after voiding.

In view of the last statement a series of freshly passed urines were collected and exposed to direct daylight and to the air in long narrow test tubes and the reactions observes daily for a week. Half of the series remained positive for the aldehyde reaction for the whole week. Of those that remained positive three were acid in reaction and two were alkaline. The accompanying table is self explanatory.

a group of twenty-five patients whose urines were examined seventy-five times and only forty-eight reactions were positive. These patients represent medical, surgical, and gynecological ailments. In a majority of the cases the other chemical and the microscopical analyses were negative. In many instances there were no diseases which could be explained by any of the above theories as the etiological factor for the urobilinuria.

In the next series of cases it is instructive to observe that two or more patients suffering with the same ailments as those in Table II, with a few exceptions, gave negative tests.

Of the patients not occurring in Table III. are the following: one case each of splenic anemia, pyopneumothorax, lung abscess, tabes dorsalis, and

*Examined at Willard Parker Hospital, Department of Health, N. Y. City, through the courtesy of Dr. Wilson and Dr. Hertzfeld.
†Seven cases of scarlet fever were complicated by chickenpox.

It is evident from the foregoing that the reaction may be positive independent of the acidity or alkalinity of the urine, in a few instances, even for a week.

Pathological Cases.—In a series of 500 urine analyses of 214 patients with the aldehyde reagent performed independently of the clinical, operative, or post-mortem diagnoses, the following table shows

atrophic cirrhosis which gave positive reactions and because of the infrequency of these types of cases in the hospital I was unable to examine more than those noted, in order to compare any coincidence.

Kamsarakan[34] examined 155 cases of scarlet fever and obtained 100 per cent. positive reactions. Out of 214 analyses of 147 patients' urines only 106 or 47.6 per cent. gave a positive result. He also ex-

amined 84 diphtheria urines and noted 54 positive or 64 per cent. in comparison to 67 analyses on 47 patients with 54 positive or 80.6 per cent. Among his other findings which do not coincide with the above results, it may be mentioned that he obtained negative results in the initial stage of pneumonia, in chicken pox, in typhoid fever, measles, and mumps. Rach and Reuss[35] tested 51 measles urines and observed 47 or 92 per cent. to be positive in contrast to the Kamsarakan's[34] negative findings and 36 per cent. positive cases in my results. They contend that the reaction continued positive for a few days and was always mild. In their series direct complications did not affect the urobilinuria. They also hold that is was never observed till the end of the eruptive stage. Schelenz[36] noted positive reactions in his scarlet fever urines almost constantly and concluded that hexamethylamine interfered with the test which I was not able to confirm. Umber[37] depended on this reagent to differentiate the anaphylactic red rash of diphtheria antitoxin from true scarlet. The basis for this observation depended upon finding 93 out of 96 true scarlet urines positive. In 60 serum rash urines, 59 were negative. Simon[31] mentioned that his results were negative in measles, scarlet, and diphtheria. The summary of his findings is as follows: Not all cases of typhoid, pneumonia, appendicitis, icterus, and tuberculosis showed positive urines. In many instances a positive diazo reaction was also obtained. He considered rapid wasting an important etiological factor of its appearance in the urine and cited a case in which recovery after such an illness coincided with the disappearance of a positive urobiliniuria, but he failed to explain the corresponding pathological changes associated with this manifestation. Similar findings were recorded by Clemens;[38] 6 out of 9 cases of appendicitis gave positive results; 3 cases of carcinoma of the stomach showed one positive test; one case of chronic constipation was positive; one empyema urine was negative; 9 out of 26 cases of pulmonary tuberculosis were positive; negative reactions were noted in a case of acute endo- and pericarditis; a case of nephritis and one of cystitis; a case of pseudodiphtheria was also negative; 3 out of 6 cases of facial erysipelas were positive; 2 out of 3 typhoids were positive. Cases of articular rheumatism were also positive. Out of 6 cases of measles 2 were positive; diabetic urines were negative.

Koziczkowsky[39] examined the urines of five fatal cases of pulmonary tuberculosis and obtained positive results in all, but temporarily positive urines were obtained in five other cases of tuberculosis. The negative results occurred coincident with improvement. He also made a comparison between the incidence of the indican and the aldehyde reactions, but he was unable to deduce any relationship. These findings were corroborated by me in normal and pathological urines at the Beth Israel Hospital. We (Hertzfeld and Berkowitz) also confirmed these findings in measles, scarlet and diphtheria in Willard Parker Hospital. We also attempted to make a study of the relation of the indican, aldehyde, and Russo reactions with practically a negative outcome.

The findings in erysipelas also vary from negative tests in two cases[6] to 100 per cent. in 183 cases.[26] The former observer also obtained negative results in scarlet fever and in typhoid fever.

Do extraneous substances interfere with the aldehyde reaction? Schelenz[36] infers that the administration of hexamethylamin (urotropin) influences positive results and makes them negative. This drug is excreted in the urine as formalin and unchanged urotropin. Both of these chemicals were added to six positive urines and observed daily for a period of three days. The urines were examined daily, but gave positive results with a diminution of the intensity. Controls were also observed for comparison.

Attempts were made to study the effect of urinary preservatives upon the reaction. These tests were made as follows: To three sets of test tubes containing 20 c.c. of positively reacting urine five drops of chloroform, 5 per cent. solution of formalin, toluol, and a saturated watery solution of thymol were added and allowed to stand for seventy-two hours. They were examined from day to day and compared with controls. In each urine containing the formalin the intensity of the reaction was somewhat diminished, but the test remained positive.

TABLE V.

THE ALDEHYDE REACTION AFTER ADDITION OF EXTRANEOUS SUBSTANCES—URINARY PRESERVATIVES.

	Time	Control	Formalin, 5 per Cent	Thymol	Chloroform	Toluol
W.	Fresh	++	++	++	++	++
	24 hours	++ (H)	+ (H)	++ (H)	++ (H)	++ (H)
	48 hours	+ (H)	+ (H)	++ (H)	+ (H)	+ (H)
	72 hours	+ (H)	+ (H)	+ (H)	+ (H)	+ (H)
G.	Fresh	++	++	++	++	++
	24 hours	+	+ (H)	+	+	+
	48 hours	+	+ (H)	+	+	+
	72 hours	+	+ (H)	+	+	+
B.	Fresh	++	++	++	++	++
	24 hours	+	+ (H)	+	+	+
	48 hours	+	+ (H)	+ (H)	+	+
	72 hours	+	+ (H)	+ (H)	+	+

The other extraneous substances observed may be classed in the following groups: of amines and amides, urotropin and chinosal; of aldehydes, formalin, lactose, and chloral; of glucosids, amygdalin; of ring compounds, mandelic and salicylous acids. All substances were used in watery solutions except salicylous acid which was dissolved in 95 per cent. alcohol and 5 drops added to 5 c.c. of positive urine followed by a few drops to one c.c. of the reagent and allowed to stand for a few minutes before the readings were made. Also 5 c.c. of urine to which only the reagent was added in the usual manner was kept for control. To rule out any error that might arise from the extraneous substance, it was also tested but with negative results. That these extraneous substances have no effect on positive urines, within twelve hours after voiding, was successfully proven on a series of six individuals' specimens.

Conclusions.—The confusion that occurs in trying to arrive at any logical conclusions in the above report surely limits the value of Ehrlich's aldehyde reaction for the appearance of urobilin in the urine.

I take this opportunity to thank Dr. Max Kahn, director of the chemical laboratory of the Beth Israel Hospital, for suggesting this problem, and for permission to use the material required for carrying out this work.

A NEW VESICAL CALCULUS EVACUATOR.*

By MARTIN W. WARE, M.D.,

NEW YORK.

Whereas the acme of perfection has been attained in the construction of lithothrites, a defect always rested with the evacuators used to remove the debris.

The earliest type of this instrument—the Bigelow—in a modified form survives to this day. At its best it is a complicated and costly apparatus. It is to the great credit of the late Dr. Chismore, to have devised the very simple all-rubber bulb evacuator, with the glass reservoir. Those familiar with its use are unsparing in their praise in pronouncing it as the "last word" in the construction of evacuators.

An extended experience with the Chismore apparatus, however, has led me to detect some defects inherent in it, because of the large amount of rubber that enters into its construction, for the manufacture of a perfect Chismore bulb even in expert hands is a matter of considerable difficulty. Many have to be discarded since the outlets for catheter and reservoir contain air holes, arising in the molding and vulcanizing of the rubber. This it is which materially adds to the cost of the bulbs. Then, either from disuse or oft-repeated sterilization, the rubber deteriorates and it is no longer possible to

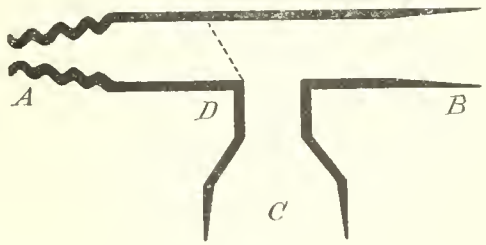

Fig. 1.

obtain a watertight coupling with the glass reservoir or the evacuating catheter. Hence the necessity arises of always having a new reserve bulb of recent manufacture to guard against breakdown.

To overcome these defects, my endeavor was to reproduce an instrument of the Chismore type with the minimum of rubber. I believe that I have accomplished this in the instrument herein depicted. It may best be described as a T tube (Fig. 1) with three outlets modified: The one at "*A*" corrugated and tapering to accommodate the coupling of variably sized rubber bulbs with varying outlets; the

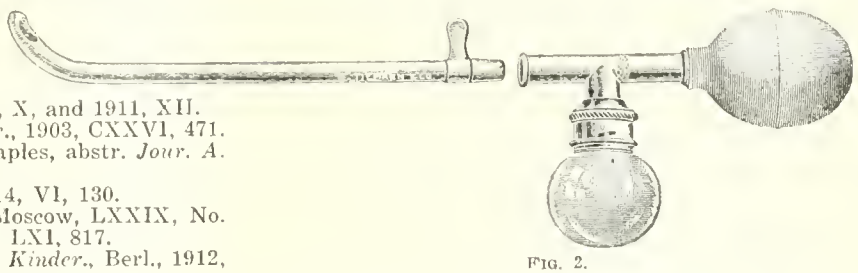

Fig. 2.

outlet at "*B*" is ground so as to effect an absolute occlusion with the corresponding cone-shaped end of the evacuating catheter; the vertical end of the T, "*C*" expands into a hood the orifice of which is also ground to insure an accurate coupling with the cone-shaped metal investment of the neck of the glass reservoir. Escape of the bottle by pressure of water is guarded against by bayonette catches. In the interior of the T tube at the angle (D) a sieve is placed at an incline, which prevents fragments of the stone being drawn into the bulb, at the same time directing them into the bottle. The advantages claimed for this evacuator are its construction in greater part of metal and glass, with an irreducible minimum of rubber, which insures its durability, reliability, and permanence of action.

It can be readily sterilized with other instruments in the sterilizer. A longer life for the rubber bulb is possible if it be sterilized after preliminary cleansing in the autoclave, as we are wont to treat rubber gloves. The bulb provided with this outfit has a capacity of two ounces. The tapering corrugated end of the aforesaid tube permits of the use of any rubber bulb or improvised rubber ball, in an emergency.

A material advantage is the low cost of the instrument and the economic feature is that only the rubber bulb of inconsequential cost calls for renewal. Repeated trials have convinced me of the perfect action of this instrument (Fig. 2), manufactured by Tiemann & Co.

27 East Eighty-first Street.

LITHIASIS IN THE BRANCHES OF THE HEPATIC DUCT.

AFTER operations for the removal of bilary calculi it occasionally happens that there is a cessation of all obstructive symptoms for some weeks or months, only to be followed by a recurrence of symptoms pointing to the retention and impaction of calculi in the gall-ducts. When this complication occurs it is usually thought that a small removable calculus was overlooked at the first operation and the surgeon is often condemned for careless work. While this judgment may be just in some instances, it is by no means so in all cases. It has long been known that calculi may occasionally be found not only in the main hepatic duct, but also in its branches, right and left, and even in their further intrahepatic subdivisions, as pointed out by Cruveilhier, Courvoisier, and others. In these cases it may be impossible for the surgeon to appreciate by palpatation or other diagnostic means at the time of operation that small concretions still remain in the upper bile passages.

Quénu and Mathieu have shown why, even with the most painstaking care, some calculi may occasionally be left, especially when they are fixed in the branches of division of the hepatic duct. These calculi may or may not be accompanied by stones in the common duct or intrahepatic bile passages, and appear to be especially characterized by their fixity, their firm adherence to the walls of the canal in which they are enclosed. There is sometimes such an accumulation of calculi that all the biliary passages—gall-bladder, common duct, hepatic duct and all its branches are stuffed with calculi piled one upon the other, for which condition Quénu suggests the term *total* lithiasis. The identity of form, consistence, and structure of these calculi suggest a common origin, namely, the gall-bladder, the usual place for the formation of calculi. In cases of total lithiasis, the considerable number of calculi and, above all, their extremely small size, explain perfectly why some of them can escape the most careful exploration. In spite of all difficulties, operation in these cases is generally followed by a good result. When the case is one of intrahepatic lithiasis, intervention is only exceptionally practicable. It is very important to bear in mind the possible occurrence of these intrahepatic calculi, for they probably explain the origin of certain stones found later in the extrahepatic passages, and their existence considerably clouds the prognosis. Calculi localized in the branches of the hepatic duct usually do not attain the considerable volume of calculi in the common duct, as they seldom exceed the dimensions of a small hazelnut, or even of a pea. They may be elongated and of an irregularly cylindrical form. The very small concretions are the most frequent but one may encounter all the intermediary sizes. The stones may be facetted, but ordinarily the surface is rough and the color a blackish brown. Their consistence is soft and friable, though certain portions of them may be quite hard. One fact important to note is the frequent adherence of the calculus to the wall of the hepatic ducts. There is sometimes a regular incrustation of this wall, prolonged to a greater or lesser extent even into the intrahepatic ramifications. There do not appear to be any clearcut special signs or symptoms characterizing calculi in the branches of the hepatic duct, though Quénu and Mathieu have found in such cases a lithiasis of the principal duct with well accentuated symptoms, but with an unusual evolution. Ordinarily there is a history of long-standing lithiasis, the patient having suffered for many years and having had repeated painful crises, more or less exactly referred to their true cause, then icterus appears, to disappear or persist in varying degree. Elevations of temperature occur, and the clinical picture is, on the whole, sufficiently sharp so that one ought always to regard the diagnosis of lithiasis of the principal duct as probable, but it is almost impossible to foretell the exact situation of the calculi. The pains seem particularly acute.

The necessity for operation is unquestionable when one suspects lithiasis of the hepatic duct. The accentuated symptoms of biliary retention that the patients present do not permit hesitation, and besides this we know the gravity of the prognosis in such cases. The common duct is first explored. If it is dilated and a calculus is perceptible at this level, incision of the common duct precedes all exploration of the passages above. That is a fixed rule; but a negative exploration of the lower parts of the biliary tree shall not lead one to neglect exploration of the hilum. This exploration, if the choledochus is incised, is done by catheterism and palpation at the same time. When the principal duct is incised the absence of flow of bile points to obstruction above; but even if the bile flows the catheterization will still be necessary, although it is not always satisfactory as the bougie may pass calculi without revealing their presence. Exploration with the finger introduced into the duct toward the liver is better, but none of these procedures is absolutely sure. Palpation of the biliary passages at the level of the hilum is not always easy; on the contrary, it is usually very difficult to get the branches of the hepatic duct between the fingers and an exact knowledge of the anatomy of the region of the hilum is necessary before operative intervention, particularly as the hepatic duct may divide into three or even four branches before reaching the liver, where it gradually splits up into its ultimate ramifications.

Operations upon the superior passages are usually rather difficult, particularly in fat subjects. The absence of bile flow, internal exploration by incision of the common duct, or palpation in the region of the hilum would lead one to suspect the existence of a calculus in the upper passages, but it is rather rare that intracanalicular manipulation with a metallic instrument is able to bring it down. Failing in this, one must incise the upper biliary ducts. Sometimes direct incision upon the calculus will suffice; sometimes, and this is the more frequent, one must have recourse to incision from place to place in the hepatic duct and its branches. If the calculi are free, if their development is limited to accessible parts of the ducts, the problem is easily enough solved and complete extraction is possible. It is far different if the calculi are adherent to the walls of the canals, if they are small and numerous, if they extend into the secondary and tertiary branches and, above all, if the case is one of intrahepatic lithiasis. Then, no surgeon can say that all calculi have been removed. The extraction of calculi having been pushed to the maximum, it is necessary to establish drainage of the incised ducts and to tamponnade, the drainage being kept up for a long time in order to free the liver from concretions, should any have been left in spite of the most careful search.

GAS GANGRENE.

ALL great wars bring their own peculiar medical and surgical problems. The armies of Napoleon contracted trachoma in the Egyptian campaign. Typhoid fever was the chief cause of death in the Spanish-American War. Hospital gangrene was the bane of the surgeons during the Civil War. So far during the present European conflict we have heard comparatively little of diseases as a factor in determining issues. Owing to the high state of development of the medical corps of modern armies it is not probable that any of the old, time-worn, devastating camp diseases will work great havoc. Cholera, typhoid, smallpox, measles, and pneumonia will possibly claim a small share of the general mortality rate, but increased efficiency in preventive measures will largely eliminate the danger of widespread epidemics from these diseases. It is the new and unknown which hold the greatest possibility of disaster.

Malignant edema has been known as a dangerous disease for many a decade, but the possibility of its appearing in epidemic form has never been discussed in any text books of medicine or surgery. Now it seems that a surgical gangrene closely resembling if not identical with malignant edema has broken out among the wounded soldiers of both armies on French and Belgian soil. This peculiar form of surgical complication has received the name of "gas gangrene." It is liable to affect any wound, whether serious or trivial. It has caused so much mortality that it has been made the subject of a special report to the English Secretary of the War Office from the Field Laboratories of the Allies. The report is published in the *Lancet* for November 28, and from it we learn that the medical corps and field laboratories are busily engaged in efforts to combat the fearful ravages of this complication of the wounds of modern warfare. From the data so far available it appears that "gas gangrene" is always due to a traumatic infection; that is, the projectile carries infected soil into the wound. The nature of this infection is not yet definitely determined in all its details, but sufficient has been learned to make sure that the particular organism belongs to the malignant edema type. In other words, it is an anaerobic, spore-forming, gas-producing bacillus. A rapidly fatal gangrene supervenes upon the implantation of the organism in the tissues. There is no pus infection except at the edges of the wound, but a dark gray discoloration which subsequently turns green and is accompanied by subcutaneous gas infiltration, rapidly involves the whole extremity, and within thirty-six hours from the receipt of the injury the process has extended so far that amputation is frequently the only chance of saving the life of the patient. From a perusal of the report it would seem that this alternative is often a very doubtful one, because hand in hand with the extension of the local trouble there goes a cardiac depression so great that death usually occurs in spite of all treatment. Consciousness is preserved till the last. There is no delirium, very litle fever, and practically no circulatory acceleration, but the heart becomes so weak that its sounds are scarcely perceptible and the radial pulse disappears entirely. The odor from the gangrenous parts is described as being not only diagnostic but also unbearable. So fearful is this smell that a properly conducted autopsy is almost impossible.

The laceration of the tissues and extravasation of blood caused by the tearing wounds of modern shrapnel seem to produce a most favorable nidus for the growth of anaerobic bacteria. Anaerobic microorganisms like those of tetanus and malignant edema find their most favorable habitat in barnyard and cultivated soil.

SUDDEN DEATH.

THE mystery of sudden death in the absence of all known causal elements has often been the subject of medical and especially of forensic discussion. The monograph by Brouardel on "Death and Sudden Death" published many years ago in English was undoubtedly of service in calling the attention of the American public to this subject, and we continue to hear of cases of thymus-death and other symptomatic deaths (which upon analysis seem to involve the status thymicolymphaticus as the chief factor). A careful review of the conditions which lead up to sudden death shows a great lack of unanimity. Given there are one or two inevitable causes the secondary factors are very numerous. At a meeting last spring of the Niederrheinische Gesellschaft für Natur- und Heilkunde in Bonn (*Deutsche medizinische Wochenschrift*, November 12) Ungar related a case of sudden death preceded by hysteriform crises. With many phenomena of hysteria there were no stigmata, paralyses, or contractures. The crises were motor and accompanied by cries. The woman came out of this state and seemed to be nearly normal. In the midst of this new health she was seized with attacks of pain in the head and neck, had motor crises with weeping, etc. She emerged from this seizure but within a short time

had another epileptoid attack, with exposure of the genitals. The whole picture was highly hysteroid. The crises became more frequent and severe until death took place, apparently from sudden cessation of respiration. At autopsy pronounced lesions were found in the ventricular region of the brain. The case is valuable as showing that clinical hysteria may end fatally; the practitioner, confronted with these crises, must remember that a fatal ending is by no means excluded.

Total Alopecia Following Traumatism.

In a war of the dimensions of the present conflict, if we bear in mind the great contemporaneous advances in the medical sciences, it should be possible to illuminate many obscure recesses of clinical pathology, to rescue from a former state of oblivion much truth, and to condemn for all time much false teaching which has become part of the established order. The peculiar behavior of the hair under conditions of severe injury and mental stress has often been taught by the isolated example. We refer here to the sudden shedding or blanching of the hair. Thus far nothing typical, nothing which connects cause and effect, has ever been demonstrated. At a meeting last summer of the Berlin Medical Society —before the present war—(*Berliner klinische Wochenschrift*, November 16), Frank reported a case of thoracic injury, in which 10 days after the accident the hair began to fall out. The broken ribs healed promptly, but the hair shedding proceeded, and in three months there was total loss of hair over the entire body. This depilation extended to all localities and even the vibrissæ of the nose fell out. The victim sought reimbursement on the ground that his baldness exposed him to draughts and catching cold. It can be shown that partial alopecia is often of traumatic (reflex) origin but total alopecia must be dependent on a neurotic element in which psychic shock is actively concerned. The psychic shock stands in close relationship to the physical trauma. The innervation of the trophic nerves is often disturbed by these accidents; and as a result of some inhibition in the centrifugal impulse, the hairs fall off.

News of the Week.

For the Relief of Belgian Physicians.—At a meeting of the Committee of American Physicians for the Aid of the Belgian Profession, held in New York City on December 20, a permanent organization was effected and the following officers were elected: *Chairman*, Dr. Franklin H. Martin of Chicago; *Vice-Chairman*, Dr. W. L. Rodman of Philadelphia; *Secretary*, Dr. Howard C. Taylor of New York; *Treasurer*, Dr. Frank F. Simpson of Pittsburgh; *Executive Committee*, Drs. Franklin H. Martin, J. Riddle Goffe, Howard C. Taylor, and Frank F. Simpson. All supplies purchased by the Committee will be forwarded to Belgium and distributed free of charge by the Commission for Belgian Relief. The supplies forwarded by this commission are packed in boxes marked with distinctive bands for each of the classes to be relieved: a box with a green band for infants and children, a blue band for invalids and convalescents, and a red band for healthy adults; the boxes holding supplies for physicians will bear a yellow stripe. Contributions for the Belgian doctors should be sent by money order or check to the order of Dr. Frank F. Simpson, 7048 Jenkins Arcade, Pittsburgh, Pa. Acknowledgment will be made in the medical journals each week of the amounts received.

New York City Death Rate.—During the week ending December 12 there were 1,338 deaths in this city, giving a death rate of 12.50 per 1,000, as compared with 1,343 deaths and a rate of 13.04 for the corresponding week last year—a decrease of 5 deaths and 0.54 of a point in the rate, equivalent to a relative decrease of 58 deaths. The most noteworthy feature of the mortality as compared with that of the corresponding week in 1913 was the large increase in the deaths from acute respiratory diseases, especially pneumonia; there were 119 deaths from lobar pneumonia and 95 from bronchopneumonia, as compared with 86 and 81 respectively during the corresponding week last year. For the week ending December 19 the death rate was 13.09 per 1,000, approximately 0.8 of a point lower than that of the corresponding week of 1913. The death rate for the first fifty-one weeks of this year was 13.41 per 1,000 as compared with 13.78 during 1913. If this decrease is maintained during the last week of the year a saving of 2,056 lives will be recorded.

Cheaper Radium.—In his annual report, Director Joseph A. Holmes of the U. S. Bureau of Mines says that chemists and engineers of the bureau have demonstrated that a process they have devised for the extraction of radium from ores can be successfully used on a large scale and will prove more efficient than that used by the largest foreign producers of radium. Through this process it is possible that the cost of radium to the consumer will be reduced to one-third of the present price. The process is to be patented and dedicated to the public. Radium now sells at $120,000 a gram, but can be produced by the new process for $40,000 a gram, thus bringing it within the range of possibility for many small hospitals to purchase a supply.

Disinfection of Subway and Elevated Cars.—In the *Bulletin* of the New York City Health Department a letter is printed from the general manager of the Interborough Rapid Transit Company, announcing that the company has decided to discontinue the use of disinfectants in its cars, relying rather upon frequent airing and thorough mechanical cleansing of the floors and all points of contact.

Additional Red Cross Surgeons.—Three American surgeons sailed last Saturday for foreign service under the American Red Cross. Dr. P. A. Smith, sailing on the *Potsdam*, is from Enid, Okla. He will be the third assistant staff officer at the Imperial Royal Reserve Hospital in Vienna. The two other surgeons, who sailed on the *Dwinsk* for Russia, are Dr. John Mann of Petersburg, Va., and Dr. T. L. Haslett of Pittsburgh.

The American Ambulance of Paris, in announcing recently the receipt of $800 said that there was on hand now enough money only to run the hospital for three months longer, a short period compared with the probable demands which will be made on it.

Praise for an American Surgeon.—In a despatch from Belgrade published in the New York *Times* mention is made of the good work done by Dr. Edward W. Ryan, Director of the American Red Cross, during and just preceding the occupation of Belgrade by the Austrians. Having volunteered to stay when the Serbs left, he preserved order for forty-eight hours preceding the Austrian entry, and protected all the Servian wounded and fed them.

To Start an American Red Cross Hospital near Metz.—Dr. Nordhoff-Jung, a woman physician connected with the American Red Cross Hospital in Munich, has reported to the Red Cross headquarters in Washington that steps are being taken for the establishment of a large American Red Cross hospital near the battle front in the vicinity of Metz for the care of the wounded whose condition is too serious to permit their removal to greater distances. She says all the available hospitals are filled with wounded from the armies along the southern German border and that German, French, and British wounded are being crowded into private residences in Munich.

Personal.—Dr. Samuel G. Dixon was recently elected president of the Philadelphia Academy of Natural Sciences for the nineteenth successive time.

Dr. J. Herbert Claiborne has been elected surgeon of the Veteran Corps of Artillery, to succeed Dr. Thomas M. Cheesman, who recently resigned. Dr. Claiborne is a veteran of Squadron A, N. G. N. Y., and was at one time a surgeon attached to the staff of the Twelfth New York Infantry, with which command he went to the front in the Spanish-American war.

Dr. Alexis Carrel of the Rockefeller Institute in this city, now a surgeon in the French army, was until recently in charge of a military hospital in Lyons. At present he is making a tour of inspection of the French military hospitals at the front.

Medical Societies Elections.—The Tri-State Medical Society of Texas, Louisiana, and Arkansas, meeting in Shreveport, La., on December 8 and 9, elected the following officers: *President*, Dr. W. G. Hartt of Marshall, Texas; *Vice-Presidents*, Dr. E. H. Martin of Hot Springs, Ark., Dr. Oscar Dowling of Shreveport, La., and Dr. E. L. Beck of Texarkana, Texas; *Secretary and Treasurer*, Dr. J. M. Bodenheimer of Shreveport, La. The next meeting will be held in Marshall, Texas.

The Twin City Medical Association at its meeting in Neenah, Wis., on December 7, elected the following officers: *President*, Dr. S. D. Underwood; *Vice-President*, Dr. E. C. Dollard; *Secretary-Treasurer*, Dr. G. M. Williamson.

The Des Moines, Ia., County Medical Society, at its meeting in Burlington, December 9, elected the following officers: *President*, Dr. A. H. Vorwerk, Burlington; *Vice-President*, Dr. J. P. Mathias, Mediapolis; *Secretary and Treasurer*, Dr. E. A. Hunt, Burlington; *Censor*, Dr. G. A. Chilgren, Burlington.

The Madison County, Ill., Medical Society elected the following officers at its meeting in Alton on December 4: *President*, Dr. L. G. Burroughs of Collinsville; *Vice-President*, Dr. R. D. Luster of Granite City; *Secretary*, Dr. E. W. Fiegenbaum of Edwardsville; *Treasurer*, Dr. R. S. Barnsback of Edwardsville.

The Jay County, Ind., Medical Association, meeting at Pennville on December 10 elected the following officers for the coming year: *President*, Dr. M. M. Moran; *Vice-President*, Dr. E. C. Garber of Dunkirk; *Secretary and Treasurer*, Dr. George V. Cring, Portland; *Chairman, Board of Censorship*, Dr. W. D. Schwartz.

The Medical Society of the County of Chautauqua, N. Y., at its meeting in Jamestown on December 8, elected the following officers: *President*, Dr. Fred C. Rice of Ripley; *Vice-Presidents*, Dr. A. Wilson Dods of Fredonia, and Dr. J. H. Kellogg of Bemus Point; *Secretary*, Dr. J. W. Morris of Jamestown; *Treasurer*, Dr. George F. Smith of Falconer; *Censor*, Dr. Morris N. Bemus of Jamestown; *Delegate to the Medical Society of the State of New York*, Dr. V. M. Griswold of Fredonia; *Alternate*, Dr. G. W. Cottis of Jamestown.

Hospital News.—The Utah-Idaho Hospital at Logan, Utah, was dedicated with appropriate ceremonies on December 3.

The Isolation Hospital for the treatment of contagious diseases in New Haven, Conn., was opened for public inspection on December 11-13, and on December 15 opened its doors for the reception of patients. The building is on the grounds of the New Haven Hospital. The building cost approximately $150,000, of which $75,000 was contributed by the city, $40,000 by friends of the hospital and the balance appropriated from the unrestricted funds of the hospital.

Charitable Bequests.—By the will of the late Margaret McLean of Philadelphia the sum of $2,400 is bequeathed to the Germantown Hospital and Dispensary.

By the will of the late Joseph Steidler of Pittsburgh, Pa., the sum of $400 is bequeathed to the Jewish Hospital Association of Philadelphia.

The Late Dr. Peabody.—At a meeting of the Association of Alumni of the New York Hospital, held December 16, the following preamble and resolutions were adopted:

Whereas, it has seemed good in the sight of Almighty God to withdraw from our midst our associate, Dr. George Livingston Peabody, so long connected with the New York Hospital, a man eminent in his profession as pathologist, physician, and teacher, wise in counsel, loyal in friendship, realizing always in his work the highest ideal and the loftiest sense of duty, and one moreover personally dear to so many of us;

Therefore, be it *Resolved*, that we, the Association of the Alumni of the New York Hospital, extend to his family our deepest sympathy and expressions of the esteem and affection which we have always entertained toward our old associate and friend; and be it

Resolved, that these resolutions be engrossed upon the minutes and a copy be sent to the leading medical papers of the city.

Obituary Notes.—Dr. Henry Garrett Voorhees de Hart of White Plains, N. Y., a graduate of the College of Physicians and Surgeons, New York, in 1873, one of the organizers and for many years a member of the medical attending staff of the White Plains Hospital, died at the hospital on December 14, aged sixty-five years.

Dr. Frank McWilliams died at Schuylkill Haven, Pa., on December 16 at the age of forty years as a result of pneumonia. He was graduated from the medical department of the University of Pennsylvania in the class of 1899. He was for a number of years connected with the medical staff of St. Joseph's Hospital at Reading, Pa.

Dr. Julius L. Friedler of New York, a graduate of the University and Bellevue Hospital Medical College, New York, in 1889, died at his home on December 13, aged fifty-nine years.

Dr. Alexander P. O'Malley died at Wilkes-Barre, Pa., on December 12 at the age of sixty-one years. He was graduated from the New York University Medical College in the class of 1876.

Dr. Roland H. Gilman died at Williamsburg, Pa., on December 17 as a result of pleuro-pneu-

monia. He was graduated from the Medico-Chirurgical College of Philadelphia.

Dr. THOMAS OSBORNE HUNTER of Biloxi, Miss., a graduate of the Memphis Hospital Medical College, Memphis Tenn., in 1889, and for several years city health officer of Biloxi, died suddenly of heart disease on December 3, aged forty-six years.

Dr. WINFIELD S. SMITH of Boston, Mass., a graduate of the Boston University School of Medicine in 1883, a former president of the Massachusetts Medical Society and of the Surgical and Gynecological Society of Massachusetts and professor of operative surgery in Boston University, died at his home on December 16.

Dr. THOMAS WILFRED FLOOD of Haverhill, Mass., a graduate of the Baltimore University School of Medicine, Baltimore, Md., in 1902, died at his home of typhoid fever on December 16, aged thirty-one years.

Dr. CHARLES WILLIAM TRUEHEART of Galveston Texas, a graduate of the Medical College of Virginia, Richmond, in 1864, for many years city health officer of Galveston, and a member of the American Medical Association, the State Medical Association of Texas, and the Galveston County Medical Society, died in San Antonio on December 15, aged seventy-seven years.

Dr. GEORGE NICHOLS of Brooklyn, N. Y., a graduate of the Hahnemann Medical College and Hospital, Chicago in 1861, and a member of the Kings County Homeopathic Medical Society, died at his home on December 19, aged eighty-five years.

Correspondence.

OUR LONDON LETTER.

(From Our Regular Correspondent.)

GENERAL MEDICAL COUNCIL—ADMISSION TO QUALIFICATION TESTS TO BE MAINTAINED—ADJOURNED DISCUSSION AT MEDICAL SOCIETY ON WOUNDS IN WAR—OBITUARY.

LONDON, December 4, 1914.

THE General Medical Council has been holding its 100th session and transacting the usual amount of formal but necessary business. Education and registration—to complete its full name—have, of course, the first claim on its attention and all matters relating thereto occupy it at every meeting. But even into the proceedings of this staid body the subject of the war has intruded just as it does into every department of our life. As the authority regulating medical education and practice, the most important of its deliberations on this occasion was the question submitted by several of the qualifying corporations whether, in prospect of the demands on the profession probably leadng to a shortage of practitioners in the future, it would be well to modify or suspend some of the minor regulations, so that students who enlist for the war might on its conclusion find that their military service had not unduly injured their medical curriculum? Further, the question arose whether the Council would approve the proposal of some bodies to hold special additional examinations so as to be able to grant diplomas to students who had completed the curriculum and had only to wait till the next ordinary examination to undergo the final test—thus hastening for a few weeks their qualification to enter the Army Medical Service?

Now, the requirements of the Council have always been met by the regulations of the qualifying bodies and represent what has been determined to be the minimum standard and that cannot be less for the military or naval than for the civilian patient. The Council evidently felt that a firm adherence to their position was called for and that it was their duty to maintain unimpaired the present standard of knowledge and skill which they have heretofore demanded from everyone seeking admission to the status and privileges of registered practitioners.

At the adjourned discussion of the Medical Society of London on the "Treatment of Wounds in War," Mr. d'Arcy Power said the cases he had seen in the present war were mostly bullet or shrapnel wounds; he had met with none due to bayonet, lance or sword. He showed a skiagram of foreign bodies lodged in the erector spinæ. Two of them were sovereigns driven out of a money belt an officer was wearing on to the transverse process of the first lumbar vertebra, which was smashed; the coins were twisted and concave and one had on it the impression of the milled edge and part of the obverse of the one above it. In the other case a bit of the patient's diary had been driven into his thigh. The most interesting and yet difficult cases were nerve injuries. To decide whether damage was done by the bullet in its passage or where it lay in *situ* needed a skilled neurologist and expert *x*-ray photographer. Their reports would decide the surgeon's course. The bullet should be removed if still causing irritation, but would not benefit damage done in transit. Each case must be considered as to the circumstances, and experience proved that *x*-rays were not infallible guides to the position or depth of the foreign body. An extensive operation might be needed to find it or it might be missed altogether. Sloughing was more often seen than suppuration. When a bullet had passed through a limb the inlet and outlet might appear as wounds when the rest of the track was healed. When healed wounds again became painful they had to be reopened, and generally he had found pieces of clothing had been left in the tissues, causing no pain at first. Dry dressing had had to be replaced by fomentations. Iodine was useful, 1 dram of a 2½ per cent. solution in a pint of warm water applied on cotton wool. Too hot water would volatise the iodine, starch in the dressing render it inert. Time would be saved by bringing the edges together with strapping. The surgeon, Mr. Power held, needed constant help from the physician, neurologist, pathologist and radiographer. He must know when to operate and when to stay his hand. His attitude should incline away from rather than towards operating. It was better to lay wounds freely open than to plug or drain them.

Mr. Charles Symonds was glad Sir W. Sheyne had recalled to them the time when septic infection was the rule and shown that the same results would follow the same conditions wherever they prevailed and could only be met by Lister's methods. A remarkable point about the cases brought home was their septic conditions with absence of toxæmia. Did the missile sear the tissues in its passage? Certainly the constitutional effects were very different from those of equally septic wounds in civil life. He had treated flesh wounds with fomentations of boric acid. In comminuted fractures by bullet or shell he employed the same. It might seem tempting to open up and disinfect the humerus or to plate or wire the tibia, but it was better not. When a main vessel is involved or a joint opened.

the question of more active interference causes anxiety. With an exposed artery and its sheath injured he favored ligature of the main trunk above. To open a clean bullet wound, except to secure a large vessel, was not permissible. To immobilize fractures of the femur for transit he would use plating or wiring. It had been good to hear that Sir W. Cheyne had not lost faith in Listerism, and brought them back to the value of carbolic acid—the antiseptic with which his earliest and greatest trimphs had been won. Relying on that and on mercury, Mr. Symonds also admitted the power of iodine (2 per cent. in rectified spirit) in large lacerated wounds even with bone involvement. Which ingredient was the most efficient? Alcohol had some part in the work. Curiously it had in some form been applied to wounds from the earliest ages, as in circumcision. Perhaps there was more than met the eye in the use of the wine and oil of the Good Samaritan, who might be called the earliest antiseptic surgeon.

Dr. Ironside Bruce showed many radiograms of gunshot injuries and pointed out the use of *x*-rays as a guide to the operator and the difficulties which prevented the accurate information being fully obtained.

Mr. Jessop spoke of *x*-rays in ophthalmic work and related many cases of blindness arriving from the war, but which recovered.

Mr. Rowlands said most men at the front were so familiar with *a*septic surgery that they hesitated about putting strong *anti*septics into wounds. But dirty wounds must be disinfected at the earliest possible moment—that is, against invasion or multiplication of organisms. Even strong antiseptics were useless and might do harm after 24 to 36 hours, and many cases cannot be dressed within that time. He said that Mr. Turner had found picric acid, 1 per cent., dissolved in methylated spirit, cheaper and just as efficient as the iodine solution. In this war the R. A. M. C. had overcome enormous difficulties. Hope of further improvement rests upon getting the patients into base or field hospitals earlier. Perhaps motor ambulances may come into use, but bad cases must be moved as little as possible and not brought home.

Mr. Jocelyn Swan had some 2,000 cases sent to the Herbert Hospital, Woolwich, nearly all septic. They must realize the difficulties of the R. A. M. C., often working under fire—not only in the line but in the field hospitals. At Woolwich they freely opened, washed and drained these septic cases—did not sew them till sepsis was controlled. They had ten cases of tetanus in which they opened the wound, disinfected it and injected antitetanus serum in the lumbar region. Seven recovered. In eighteen skull cases the bullet entered the brain—in five traversed it completely—but two of these recovered, the depressed fracture having been attended to. He thought skull injuries should be dealt with at once, though those of thorax or abdomen were best let alone.

The president, Sir J. Bland Sutton, in closing the debate, remarked that he had himself given up carbolic acid because he was specially susceptible to its ill-effects. He used perchloride for a long time, but had lately been trying iodine and was well satisfied with it. It was a striking fact that these septic wounds cleared up rapidly with fomentations, especially peroxide of hydrogen. When the sepsis subsided foreign bodies could be cleared from the wounds, which then healed with great rapidity.

Colonel H. T. Thompson, M.D., of the Royal University of Ireland, who served for a long time in First V. B. of the Royal Fusiliers and held the V. D. and was J. P. for Croydon. He was author of a work on "The Importance of Milk Sterilization."

OUR LETTER FROM THE PHILIPPINES.

(From Our Special Correspondent.)

PHILIPPINE ISLANDS MEDICAL ASSOCIATION—ORGANIZATION OF A RED CROSS PARTY FOR THE WAR—A TRAVELING SANITARY EXHIBIT—PHILIPPINE GENERAL HOSPITAL—TYPHUS IN MINDANAO—A PLAGUE OF FLIES—WAR AGAINST MOSQUITOS—INCREASED POWERS OF THE MEDICAL LICENSING BOARD.

MANILA, November 8, 1914.

THE Philippine Islands Medical Association closed a very successful meeting with the election of its officers for the ensuing year. The new president is Col. W. D. McCaw, chief surgeon of the army in the Philippines; the vice-presidents are Lieut.-Col. S. C. Gurney of the Medical Division of the Philippine Constabulary, and Dr. A. G. Sison; secretary-treasurer is Dr. R. B. Gibson; councillors, Dr. N. M. Saleeby, Dr. W. E. Musgrave, Dr. Benito Valdez, Dr. M. W. Ireland, and Dr. Ferdinand Schmitter.

The sessions were followed by a banquet at which covers were laid for about sixty, the Secretary of the Interior and Commissioner De Veyra being guests of honor. Dr. J. A. Johnston presided as toastmaster and a number of speeches were made. Dr. N. M. Saleeby, the retiring president, pointed out the great benefits conferred, not only on the Filipinos, but upon all the peoples of the Orient through the work of the American physicians here, which had already had a profound effect upon the development of this part of the world. Dr. H. E. Eggers, of the Harvard Medical School in Shanghai, while not deprecating the work of the Shanghai doctors, pointed out the much greater difficulties encountered by the doctors in these islands. Whereas in Shanghai the most serious diseases or epidemics only occur for short periods at certain seasons, such difficult problems are always presented in Manila and have to be constantly combated. The acuteness and urgency of medical conditions were, he said, much greater here than in Shanghai. He also said that the local accomplishment in advancement of tropical medicine and hygiene were not adequately recognized by the rest of the world.

Dr. Sison delivered a masterly address on the scope and importance of the medical profession.

Mr. W. T. Denison, the Secretary of the Interior, described his particular interest in the work that the members of the association were doing, both as individuals and in relation to the health service. He felt it perhaps the most potent power for good in the islands and promised the association his earnest support in all its undertakings.

Col. W. D. McCaw, the new president, in a most polished oration, dwelt particularly on the wonderful changes which had occurred in the islands since he left them in 1902, and which had been accomplished for medical and sanitary uplift. In gracefully acknowledging the new honor which had been bestowed upon him, he pledged his best efforts to making the record of the association as brilliant as it had been under his predecessor.

Manila is much interested in the proposed formation of a Red Cross party to go to the scene of the

European war to take part in the humanitarian work there. Bishop Brent, Speaker Osmena of the Philippine Assembly, and Commissioner Palma have the matter in charge—the Philippine Red Cross having the same status toward the American Red Cross as a state society. The plan is to organize a party of three representative physicians, fifteen female nurses, with the necessary cooks and attendants to make it a unit complete in itself, and equipped with the necessary instruments, etc., to take over and operate wards of approximately 125 beds capacity. The projectors are fortunate in being able to have the advice of Col. Lynch, formerly army representative with the Red Cross, and of Major Darnell, medical supply officer, both of whom are on duty in the islands, in matters of organization, administration, and equipment. The Filipinos see in the project an opportunity to place themselves before the world on a national status and to "put the islands on the map," and are much interested in seeing that only thoroughly representative physicians and nurses shall compose the party. The society is in touch with the American Red Cross, and its party will report to the national representative now stationed in London. It is planning to be absent about eight months.

The Bureau of Health gospel of hygiene railroad car and traveling sanitary exhibit, is now ready to enter in its work and was thrown open to inspection by the public recently. Refreshments were served by pretty Filipina nurses from the General Hospital and a large number of visitors were in attendance. The exhibit is very complete and includes a moving picture outfit, and will prove very interesting and do a great deal of good. The Bureau of Education is to assist in the work of publicity by having all its pupils attend the demonstrations and lectures while the car is in their town, and by sending out notices regarding the latter through the children and by teachers, posters, etc. The health officials will, of course, cooperate, and the governors and other officials have been asked to assist in every possible way while the car is in their provinces or municipalities. The railroad towns for about 150 miles north of Manila will first be visited.

The Philippine General Hospital is still a center of newspaper interest, the latest proposition being to turn it over to a church organization which is about to discontinue the St. Paul's Hospital in the Walled City as being too great an expense. It is difficult to see how an organization that seems to have failed of successful administration of a seventy-five bed hospital could successfully manage one of five times that size. Of course, the Government, which is careful to avoid any religious complications and entanglements, will enter into no such arrangement. Another proposition is that the Philippine General Hospital should refuse to admit pay patients and become a purely charitable institution. This change would, of course, be enthusiastically received by the various private hospitals, since thereby the great burden of charity patients would be shouldered by the Government, letting the private hospitals have all the patients in whom a profit could be found. However, it hardly seems equitable to deny the wonderfully complete medical and surgical facilities of the Philippine General Hospital to people who have a few pesos they are willing to spend for treatment, and force them to go to the far less generously equipped private institutions for their care. The idea seems to be to eliminate it from competition with the smaller hospitals, so that the latter might benefit thereby—all of which might be quite desirable from the viewpoint of the latter. There are quite a number of Government employees who are entitled under their contracts to free medical treatment, and it is proposed that the Government turn them over to one of the private hospitals and pay for their treatment there. This Government free treatment seems now in a fair way to be done away with in reference to future contracts, and a bill has been introduced in the Assembly to that end. The work done at the Philippine General Hospital has its magnitude well shown by the fact that it handles about 750 patients a day, with a staff of about 40 doctors, 100 Filipino graduate nurses and 250 student nurses to handle the work. The entire personnel employed in connection with the hospital amount to over 800. The extent to which Filipinization has been accomplished is shown by the fact that of the above total only 8 are Americans, although at the outset practically all the attending and nursing staff were Americans.

Typhus fever has recently been reported as endemic in Mindanao, Dr. George B. Foster, of the United States Army, reporting five cases of Brill's disease in an outbreak at Camp Keithley, three cases occurring among native soldiers and two more in native camp-followers. A very few such cases have been diagnosed previously, but the diagnosis has not been unquestioned, and until the last year or so its existence in these islands had not been expected. Camp Keithley is located on the cool uplands at an elevation of about 2,200 feet, and the climate is apparently cool enough to enable the disease to maintain an existence. The Moros of that vicinity are squalid and filthy, seldom bathing or washing their clothes, and herding together in large houses, so that any lice present have every opportunity for migration and transference of infection. It will now be interesting to learn whether it ever occurs among the Igorrotes and other dwellers in the 5,000 and 6,000 levels of the Luzon highlands. In the past year tremendous outbreaks of typhus have occurred in Japan. With the occurrence of typhus, yellow fever appears to be the only remaining great scourge of the human race which is not established in these islands.

There are now a great many more flies in the city of Manila than there have been for a long time. This is believed to be largely due to the fact that the ants, which live in the ground and systematically prey on fly larvæ were largely killed off by the September floods, while the flies took shelter in buildings and thus kept alive. Since then the flies have reproduced themselves more rapidly than their natural enemies, the ants, and nature's balance for the suppression of flies has been temporarily disturbed. Pending the necessary increase in the ant population, the Bureau of Health has asked the public to take special measures for fly prevention and destruction. Special efforts are being made to keep down flies about the dumps. It will be recalled that some of the lowlands of Manila are being filled in with garbage and refuse. This is dumped in about 6 feet deep, and immediately covered over with clean earth to assist in decomposition and diminish odors. Unfortunately much of the garbage is flyblown before collection and constant vigilance is necessary to destroy the flies which hatch out and work their way to the surface. This is done by systematic spraying of the surface with larvacide solution every two or three hours, when the young flies and maggots are readily killed.

The work of mosquito destruction, which has been carried out by the municipal authorities, has just been turned over to the Bureau of Health. The city is to pay the necessary bills, and the health authorities are to provide the personnel, conduct the work, and take the responsibility. This mosquito work is to be conducted in connection with the work against flies and rats, the general sanitary inspection force assisting in reporting breeding places while the work of destruction is to be done by a special force. Dr. C. S. Banks, the well-known entomologist of the Bureau of Agriculture, is to conduct the work under the Bureau of Health, and is now preparing systematic plans of endeavor.

A bill has just been introduced in the Assembly by Dr. Santos, an assemblyman, calling for the examination of graduates of the medical school of the University of the Philippines by the Medical Examining Board as a prerequisite for practice. Heretofore the university graduates have been the only ones exempt from this requirement. In presenting his bill, Dr. Santos made serious charges against the competency of the students, alleging particularly that they were not made sufficiently acquainted with cholera, leprosy, plague, and other grave transmissible diseases. His allegations called forth emphatic denials and protests on the part of graduates and undergraduates of the university, and are now being investigated by the Assembly Committee on Education.

1. The Action of Lecithin Upon Tubercle Bacilli.—E. Zueblin and F. Proescher show that human tubercle bacilli subjected to the action of lecithin undergo some loss in virulence. In the case of the bovine bacilli the impairment of virulence is less marked.

2. Faradic Stimulation in Psychopathic Subjects.—G. P. Grabfield has investigated the sensory threshold for faradic stimulation in various psychopathic individuals and finds that in general the threshold of the psychopath tends to be high. Alcohol appears to be a definite factor in raising the threshold. Interesting figures are available for cases of dementia precox, indicating that the paranoidal forms have a normal threshold, whereas those classed as catatonic and hebephrenic have pathologically high thresholds. It is remarkable that the hebephrenic cases tested (two in number) showed some of the highest thresholds calculable. The manic phase of manic depressive insanity shows a normal threshold, the depressive phase a pathologically high threshold. Beyond a high threshold average, it is impossible to ascribe to the syphilitic group more than a tremendous variation in different cases. The psychoneurotics seem to have normal thresholds, which fact may be of practical value when the diagnosis is in doubt as against the frank psychoses.

3. The Lange Colloidal Gold Reaction.—H. C. Solomon and H. O. Koefod report the results of their experience with this test in 135 cerebrospinal fluids. They find that the test requires very small quantities of fluid, is rapid, easy and cheap, but must be done with great care. Paresis gives very typical reactions, but cases of undoubted paresis may give atypical reactions, and cases not paresis may give the type reaction. We are unable to offer any conclusion as to its value in the differentiation of cerebrospinal syphilis and paresis. Tabes gives a reaction quite different from paresis, fairly characteristic of syphilis, but not in itself diagnostic of tabes. It is of no certain value in cases of congenital syphilis, showing no other signs of central nervous system involvement. Non-syphilitic cases give at times reactions in the so-called syphilitic zone. In view of the above statement it can be maintained that a reaction in the syphilitic zone in cases of syphilitics does not necessarily argue syphilitic involvement of the central nervous system, all other signs being negative. It would seem to offer a differentiation of tuberculous meningitis, and is here at times more valuable than any other test.

3. The Treatment of Funnel Breast.—J. Madison Taylor describes a mechanical method of treating this condition, the essential of which method consists in forcing the chest to expand and the ribs to rise to a normal level. The patient is directed to clasp hands behind and place them just below the shoulder blades, then to pull apart one against the other, extending both steadily downward, as far as possible, maintaining both traction and extension with increasing force, and to hold them at the end of full downward extension an appreciable time—a few seconds. This maneuver involves full action of the erector spinæ muscles; as they pull down, the thorax is lifted up in front; all the ribs are elevated and likewise full traction is exerted on the ribs at their insertions into the manubrium. As an important detail, first the right hand clasps the metacarpal bones of the left hand, the fingers of the left hand remaining extended. The thumb of the clasping hand is not used; encircling the left hand twists the right and imparts the direction of pull. The movements are repeated, using alternate hands, one to clasp and one to extend; both being thrust down and pulled apart; also holding the back vertical, *i.e.* not protruding the belly. It is sufficient to make ten extensions at a time—five with each hand—and daily at least for two or three months; then two or three times a week Whatever ultimate results can be obtained depends on the degree of contraction, state of tissues, and the energy used in the motions. A further detail of importance is that the chin shall be extended directly upward with each downward thrust of the hand. The chin moves up as the hands go down and greatly adds to the uplift of the ribs and the emphasis in downward pull of the vertical muscles of the back.

7. Colon Bacillus Infection in Middle Ear Disease.—D. S. Dougherty reports twelve cases in which the association was present and alludes to the paucity of investigations as to the relative frequency of the colon

bacillus as a source of aural infection. A possible route for this organism is the Eustachian tube during postanesthetic vomiting. In four of the author's cases the source of the infection was furunculosis of the canal wall. In one case the source was a rectal abscess.

9. **Pneumococcus Peritonitis.**—L. M. Kahn concludes that this condition may exist without the presence of pneumonia, and occurs in two distinct phases: the acute diffuse peritonitis and later the localized abscess formation in the peritoneal cavity. Nothing is gained by operation during the height of the diffuse peritonitis. Every effort should be made to support the patient in the acute diffuse stage so that the infection may become localized. Provided the correct diagnosis is made, the correct time for operation is after the formation of the localized abscess.

3. **Occupational Factors in Disease.**—E. R. Hayhurst points out that occupied persons, other than agriculturists, suffer an enormous mortality (figures show 74 per cent.) from well-recognized preventable and prematurely degenerative diseases. Occupational diseases exist because industrial health hazards exist. Responsible employers do not realize the existence of either, while treating agencies take little cognizance of employments. From one-fourth to one-third of the medical afflictions of tradespersons are due in whole or in great part to industrial health hazards. In institutions the vast majority of industrial diseases are lost sight of through a failure to recognize properly the industrial relations of the patients, to make etiological diagnoses, and to classify properly in subsequent filing. Specific occupational diseases, such as lead poisoning, are not recognized in more than one out of three or four instances, more especially the chronic cases.

8. **Continuous Painless Renal Hemorrhage.**—W. M. Spitzer states that the changes found in kidneys of essential hematuria are identical with those found in passive congestion and are therefore caused by passive congestion. The bleeding is due to passive congestion, the kidney being an organ so constructed that it must of necessity bleed in the presence of passive congestion. It is erroneous to ascribe the bleeding to nephritis, as there are no clinical symptoms or urinary findings indicative of nephritis, nor can the latter be unilateral. Still, it is admitted that if the bleeding continues, the pathological changes in the kidney would be the same as in chronic interstitial nephritis. The passive congestion occurring in one kidney only is due to some interference with the outflow of blood, which comes from a twisting of the kidney on a short pedicle. Operative interference is warranted only when it becomes necessary to save the patient's life because of an increasing secondary anemia. Bisection of the kidney for the cure of this condition is contraindicated and is dangerous.

12. **Vaccination Against Epidemic Meningitis.**—J. H. Black reports the results of his supplementary studies along this line, which show that prophylactic vaccination produces a high degree of immunity in most cases. This immunity is demonstrable at the end of two years. Some individuals may show an actual increase in immune bodies at the end of one year over those demonstrable soon after vaccination. Fixation occurred with the serum of a positive control who recovered from meningitis, but this fixation did not reach as high dilutions as did that of some of those vaccinated.

3. On Some Cases of Anomalous Fever. S. Taylor.
4. Glycerin in Bromidrosis, with a Note on Military Needs. T. H. C. Benians.

1. **Problems in Mental Pathology.**—E. Goodall in the first of the Croonian Lectures discusses a few of these problems, one of the most interesting of which seems to be the relationship between syphilis and paresis. The suggestion is made that paresis is merely an unusually late manifestation of syphilis of the brain. Whereas 17 per cent. of syphilitics develop tertiary lesions in the brain, the number that develop paresis is only 5 per cent. There is a certain amount of presumptive evidence that in those syphilitics who develop paresis there is an underlying neuropathic inheritance. A close analogy is pointed out between the sleeping sickness that ensues after trypanosome infection and the general paralysis that follows syphilitic infection. The evidence is strong which tends to support the hypothesis of a toxic origin for paresis, namely, the exacerbations and remissions suggestive of a toxic process; the temperature variations of unknown causation, and the polynucleosis of the blood accompanying the exacerbations. The author refers to the recent use in cases of paresis of hexamethylenetetramine, a drug which, at any rate in institution cases tends to prolong life by maintaining the patient for a longer period in a stationary state or in a remission. Its favorable action may possibly be due to the prevention of secondary infections.

2. **Leprosy Treated with Radium and Diathermy.**—C. E. Iredell reports the case of a medical man, the superintendent of a leper asylum from 1901 to 1908, who in 1910 first noticed a sensation of pins and needles in his left arm and a little later macules on the arm with fawn-colored centers and dusky borders. The diagnosis was made of maculo-anesthetic leprosy. There developed cramps, pains, and numbness in the hands and feet and a leprome appeared on the lower lip. The *Bacillus lepræ* was isolated from the pus of this leprome, which healed under the application of radium. Pains in the abdomen were relieved by the application of diathermy. In fact the improvement in the patient's general condition began with this method of treatment.

4. **Glycerin in Bromidrosis.**—T. H. C. Berrians notes that whereas the influences underlying this condition are not quite clear, there is at least one known causative factor, namely, bacterial decomposition of

the sweat. It is suggested that the application of glycerin to the feet prevents the formation of noxious products and keeps the skin in a healthy condition.

Berliner klinische Wochenschrift.

November 9, 1914.

Perforating Shot Wounds in the Stomach.—Adler gives statistics which show that in about ⅞ per cent. of shot wounds of the abdominal cavity the stomach is perforated. The mortality from immediate laparotomy in peace surgery is about 15 per cent., but in war the corresponding figure is about 70 per cent., which is much higher than that of conservative management, and agrees closely with the peace mortality of laparotomy when done over twelve hours after the injury. The author cites the case of a soldier shot through the stomach at Gumbinen last August. He was struck at a distance of about 200 meters by an ordinary bullet. He thought he had only been hit with a stone and at first paid no attention to the injury, as fragments of stone were flying about, and he had actually been hit with one at the time of the bullet wound. He had been kneeling to shoot at the time and was bowled over by the stone but sprang to his feet. There was hardly anything in his stomach at the time. His breakfast four hours before had consisted of two cakes. He was unable to stand erect. The dressing station was reached in half an hour, and the sanitary company in another hour, when he entered a coach drawn by Russian prisoners, reaching Gumbinen in 5 hours. Ten hours were required to transport him to Insterburg on the following day and he reached Berlin from Insterburg in two days and two nights. During most of the period he sat up, and at the various stops for food ate bread, sausage and fruit, drank lemonade, and smoked cigars. The man should by rights have been interned at Insterburg, which would have saved him 48 hours of transportation in a freight car. At Berlin just four days after the injury he was found to be in excellent general condition, with no symptoms of peritoneal reaction. *X*-ray examinations showed that the projectile lay loose in the stomach. Some twelve days later it had traveled along the intestine to the cecum and eventually was found in the stools. The bullet, which had perforated only the interior wall of the empty stomach at the greater curvature, had done no harm because there was no escape of matter into the peritoneal cavity and the wound in the stomach had closed itself by adhesion formation.

Treatment of Tetanus.—Mühsam advocates some procedures which are not in general use. He would treat the wounds as if they were already infected. All shreds of tissue or any tissues which could serve as a nidus for germs should be removed by scissors and the sound surface thoroughly curetted. In certain suitable cases he would make a counter opening to insure complete drainage. No substance should be used for dressings that has reducing properties (the author unfortunately does not give a list of these but some of the most commonly used dusting powders are said to abstract oxygen from the tissues). The author advises free use of oxygenizing substances, chiefly hydrogen peroxide in the usual fluid form and also the solid form for insertion in tracts. The wound should never be cauterized or dressed with any substance which forms a protective crust. Serum should be given by the intralumbal and intramuscular routes alternately. A sufficient use of narcotics should be made, and the author, like some of his colleagues, implies under the idea of narcotic the use of magnesium sulphate. The presence of trismus prevents expectoration and thereby causes a certain amount of death from aspiration pneumonia. To forestall this possibility the author advises the extraction of enough teeth to permit expectoration. A case is related of an English wounded prisoner delivered to a reserve hospital with tetanus at its acme. The wound had been received 25 days before. The incubation period seems to have been 11 days. The patient had ill-looking wounds on both lower extremities. At each contact with the surgeons he was thrown into convulsions. Under chloroform his wounds were curetted; one of them extended into the marrow of the tibia. Serum and hydrogen peroxide were used freely, with the older narcotics. With three days of this management the patient was out of all danger.

Renal Diabetes.—DeLangen speaks of the increasing interest in this condition and describes a case in point. He concludes that in certain kinds of renal lesion pathological quantities of sugar in the blood are excreted with difficulty. There is also, so far as experiment may show, a diabetes due to abnormal permeability of the kidneys. Finally there is a true renal diabetes which differs notably from ordinary diabetes mellitus in causation, course, and prognosis. Thus far but a small number of these cases have been placed on record. Klemperer has set up certain criteria for these cases, and to be authentic reporters should not the presence or absence of these: independence of amount of sugar in urine in regard to carbohydrate ingesta; no increase in sugar content of blood; development of nephritis antagonizes excretion of sugar.

Münchener medizinische Wochenschrift.

November 10, 1914.

Superinfection in a Case of Tabes Dorsalis.—Pöhlmann reports a case of recent syphilitic infection in an elderly tabetic. This case is justly entitled to the term superinfection because in the tabetic the Wassermann reaction is practically always positive. The conditions are quite unlike those present in ordinary reinfection, which, once infrequent, have now become quite common under salvarsan treatment. Superinfection is extremely infrequent, and the word itself as applied to syphilis is barely known. The author's patient, a man of 63, had become syphilitic when a young man. Not until ten years had expired did he submit to a thorough cure. In 1913 the Wassermann reaction was negative. About a year later he contracted a clinical chancre, but without spirochetes or enlarged lymph nodes. Wassermann reaction negative. Two weeks after first appearance of chancre a positive Wassermann reaction was obtained by the use of a single technique, although other tests were negative; and the use of neosalvarsan and a mercurial inunction caused a slow recession of the chancre. No enlarged lymph nodes or secondary symptoms had as yet appeared. There was arteriosclerosis with low blood pressure and evident abnormalities of the heart and large vessels. The neurological examination revealed evidences of beginning tabes. Technically the finds are summed up as follows: Hypertrophy of the heart resulting from arteriosclerosis, aortitis (probably luetic), slight cardiac insufficiency. The eyes were normal. The evidences of tabes were highly minimal — slight anomalies of sensation and reflex action. The absence of spirochete finds and of regional adenopathy suggests that the incoming organisms were overwhelmed by persistent immune bodies in the circulation. In any case one would not expect a superinfection to behave like a primary infection or even a re-infection. The "tertiary tissues" had naturally become very largely immunized to spirochete activity in the sense of a general infection.

Danger of Anaphylaxis in the Serotherapy of Tetanus.—Simon relates several personal cases of tetanus

occurring in his practice in which antitoxin used in large doses cured the patient without any suggestion of abnormal sero reaction. Since the present war eight cases have been seen, but four of the patients were in such an advanced stage of the malady that they soon perished without relief from serum. In this series the incubation period had been very brief (3 to 6 days), the onset of symptoms very stormy, the type of disease of the severest, and the prognosis of the worst. Two of these patients were treated with serum and the other two with magnesium sulphate, but in neither series was any benefit noted. The four patients with moderately severe tetanus all recovered, but irrespective of the precise treatment two undoubtdly showed the presence of severe anaphylactic shock. Klimenko has placed on record 33 severe examples of the latter, all in recovered cases. Milder cases are doubtless more common than is believed. The great puzzle about anaphylaxis in the author's cases, to say nothing of others, is that there had been no sensitizing by previous injections. The fact that serum protection soon wears off in the case of diphtheria should have no bearing upon the author's cases, as the conditions were hostile to an anaphylaxis. One is forced to believe that some of the manufactured serums are not of equine origin, but of bovine. The author advises that after 10 days of serotherapy the use of serum should be discontinued.

Magnesium Treatment of Tetanus.—Eunike regards magnesium sulphate as the best of all the symptomatic remedies for this affection. He has followed Kocher's technique in the treatment of eight cases. These were all of the severest type, with as a rule very brief incubation period. The evolution of the disease was very rapid, and the excitability which provokes the convulsions was very high. Incidentally deglutition was almost impossible. Lumbal injections were used throughout under chloroform. The four most severe cases did not respond in the least to magnesium. Two more showed some response while in the remaining two the positive result was striking. The four uninfluenced cases all perished in from 8 to 45 hours from the first injection. Of the other four cases two certainly recovered promptly, although a second injection was required in each case to combat a recrudescence. Of the remaining two cases the author states only that the convulsions were favorably influenced but never disappeared entirely. He omits to state the termination of these cases, but if the convulsions never ceased we may infer that it was lethal. All the patients received antitoxin and the customary narcotics.

Deutsche medizinische Wochenschrift.

November 12, 1914.

Treatment of Severe Cases of Tetanus.—Kocher begins an article on this subject, and after a brief historical prelude wastes no time in taking up the magnesium sulphate treatment concerning which his very favorable views have long been known. He has been in touch with this resource for over three years, and first tested it in practice in November, 1911. On the following July he was able to report three cures of tetanus by magnesium given intradurally. This report called the attention of the profession throughout the world to new possibilities in therapy. Early in 1913 the author reported further results and his personal record was five recoveries and one death. Four subsequent cases, one treated by a colleague, left the grand total to date at seven recoveries and three fatalities—a mortality of but 30 per cent. A curious fact is now elicited, to wit: all the fatalities thus far have occurred in children. The seven recoveries were all in adults, with a mortality of zero, a record probably never equaled under the conditions. The author now proceeds to demonstrate that children treated subcutaneously do especially well under this plan. The experiences of Mielke and Falk prove this. Falk, in fact, cured three victims of trismus neonatorum with subcutaneous exhibition of magnesium. Although small series of cases of Kocher and Falk have shown 100 per cent. survival under magnesium treatment, suggesting a therapeutic conquest of tetanus, the author admits that at present we must take account of Stadler's 58 compiled cases with magnesium treatment. His own analysis fixes the mortality by the intralumbal method as but 20.5 per cent. Unfortunately separate figures for children are not deducible.

Secretion of Urine in the Nursling.—Engel states that little is known of this subject. We are indeed aware that the urine escapes involuntarily and several times daily. The amount we do not know nor the composition of the different portions. The author has in consequence devoted several years of research into this problem. A series of children was tested at half hour intervals to see if they were dry or wet. This proved to be impracticable, and a small urinal was employed to catch the urine. It was provided with an exhaust tube and two platinum electrodes which were attached to an electric circuit. The urine, escaping from the child, passed between the two electrodes and completed a circuit, thus ringing a bell. This procedure involved the escape of a portion of the urine as overflow, which in turn was caught in an accessory receptacle. As soon as the bell rang the sister in charge removed, emptied, and replaced the urinal. The author does not in this connection report results; so that his article should have been entitled "a method for collecting the urine of nurslings," which would have awakened more interest in the mind of the pediatrician.

Anosmia and Traumatic Enophthalmus.—Strebel, associated with Professor Haab, first cites the great infrequency of traumatic enophthalmus. That the olfactory nerve does not suffer more frequently in regional traumatisms has long been a paradox. This is due in part to defective methods for testing olfaction. The author now cites a case; a man was kicked by a horse about the left eye and root of the nose. Bone splinters were removed from the left lower portion of the orbital margin. There was fracture at the root of the nose. Vision in the left eye ceased at once as a probable result of extravasation of blood, the absorption of which favored enophthalmus. Another diagnosis was "opticus atrophy as result of the fracture." There was coincident paralysis of the left facialis. Examination by the author, carried to great refinements, brought out the final opinion that the fracture line extended nearly to the stylomastoid foramen, involving the facialis beyond the chorda. The fracture of the orbital margin was doubtless responsible for the enophthalmus. In other words, the horse's hoof fractured the inner portion of the orbital ring and the median orbital wall with displacement of the nasal route and laceration of the olfactory fiber. The atrophy of the postbulbar tissues which caused the enophthalmus was doubtless brought about in part by injury to the sympathetic fibers of the eye.

Perforation of the Intestine by Ascarides.—H. Plew reports the case of a three-year-old child in which a round worm perforated the duodenum and caused fatal suppurative peritonitis. It is pointed out that such perforation may occur without any preceding pathological change in the intestinal wall.—*Archiv für Kinderheilkunde.*

Insurance Medicine.

Chronic Discharging Ears and Life Insurance.—Dr. William Mithoefer points out that there are both dangerous and non-dangerous types of suppuration from the middle ear. The non-dangerous type is a true mucous membrane disease and rarely leads to grave complications. These patients have fair hearing power, being able to hear whispered voice from eight to twelve feet and suffer no other inconvenience than the appearance usually in the morning of a slight discharge from the ear. The perforations of the tympanic membrane are round or kidney shaped, and are located in the central or lower part of the membrane, in contradistinction to the perforations which are present in the dangerous types of suppuration, and are situated along the margin of the ear drum. These so-called marginal perforations are significant of bone disease, are often small and difficult to recognize. At times the only sign of their presence is an almost imperceptible mass of granulation tissue which is attached to the edge of the tympanic ring; at other times the perforation is only seen after the removal of a small crust which adheres to the margin of the perforation. Crust formation is liable to take place around a perforation of Shrapnell's membrane. Congenital perforations of Shrapnell's membrane may exist, but any perforation with crust formation around its edge at this place means that there is some inflammation behind. A perforation in this locality is often overlooked on account of the miniature size of the defect and the fact that the discharge is often scanty and intermittent and hangs over the perforation in the form of a thin film. At other times the perforation is not recognized because epidermization of the mucous membrane of the tympanum has taken place and the background of the perforation resembles the rest of the tympanic membrane. The marginal perforations and those present in Shrapnell's membrane have properly been called the dangerous types. It is extremely important that all applicants that have such perforations and in whom there is a scanty or intermittent discharge should be rejected. The degree of deafness which is present in these patients is of prognostic importance. A careful test of hearing usually demonstrates marked deafness. Whispered voice often is not heard further than two to four feet (noise apparatus in sound ear). Such marked deafness is characteristic usually of bone disease, as patients with mucous membrane disease alone have fair hearing power. Bone disease may be suspected in a patient with a marginal perforation and with considerable loss of hearing. Bone disease means chronic mastoiditis, and chronic mastoiditis with its possible intracranial and systemic complications is a dangerous and insidious disease. It is true many patients have reached old age, having had a discharging ear since childhood, but the consensus of opinion is that discharging ears, if they do not lead directly to death, certainly shorten the life of the individual. No life insurance examination is complete unless a careful inspection of the tympanic membrane is made, for frequently perforations of the drum membrane with a scanty discharge are detected upon examination, the applicant having no knowledge whatever of such a condition. It sometimes happens that patients state they have a scanty discharge from the ear, thinking that the discharge comes from the canal and not from the deeper tissues. This is partly true, as there is present an eczema of the external auditory canal, but the real cause of the eczematous inflammation is the scanty discharge of pus from a small perforation in Shrapnell's membrane. These conditions are often pathognomonic of a localized suppuration of the attic of the tympanum. In these patients with a scanty discharge it is necessary to inquire about two important symptoms, headache and dizziness. The latter is suspicious of labyrinthine involvement, the former denotes retention of pus or extension of the disease to the meninges. Headache is not always complained of even when the disease has reached the brain. Brain abscesses have been known to lie latent for a period of two years. There is a slight elevation of temperature, some loss of weight, a feeling of heaviness in the head with headache coming on at night, but not severe enough to disturb sleep. Such symptoms arouse suspicion of intracranial involvement. Central perforations, those having a peripheral zone of drum membrane between the edge of the perforation and the tympanic ring, rarely are associated with bone disease and seldom cause serious trouble. Perforations located in the region of the opening of the Eustachian tube are of a benign character and usually harmless. The most important factor to be considered is the direct extension of the disease from the middle ear to the surrounding vital structures. While the disease may be inactive for years there exists a possibility of a serious complication should the process once more become active. Mithoefer has divided applicants with discharging ears into four classes:

A.—Good Risk.—1. Complete cessation of discharge with cicatrization of the perforation. A cotton-tipped probe should be applied to the tympanic membrane, as often there is then revealed a few drops of foul-smelling pus which was not suspected on mere examination. 2. The persistence of a facial paralysis after healing of a chronic suppurative otitis media.

B.—Fair Risk.—1. Dry perforation centrally located without the existence of nasopharyngeal disease. Here there is a possibility of the middle ear becoming reinfected both from the external canal (swimming, dust, etc.) as well as through the Eustachian tube. 2. Complete healing after a radical mastoid operation.

C.—Fair Risk (increased premium).—1. Dry perforation complicated by disease of the nasal accessory sinuses of a chronic inflammation of the post-nasal space. To be considered only after treatment of the nasopharyngeal condition. 2. Incomplete healing of a radical operation, if the discharge from the ear comes from the region of the Eustachian tube and healing of the wound has taken place in the region of the attic and antrum.

D.—Bad Risk (rejection).—1. All suppurative diseases of the ear with marginal perforation and with the formation of granulations and polypi, mastoid tenderness, or a history of marked pain in the mastoid process; facial or abducens paralysis, and the presence of cholesteatomatous material in the ear. 2. Exostosis of the external canal with history of discharging ears. 3. Incomplete healing of a radical mastoid operation with the presence of denuded bone in the region of the promontory or antrum. 4. All who complain of headache or dizziness.—*Lancet-Clinic*, October 3, 1914.

Society Reports.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, Held October 15, 1914.

THE PRESIDENT, DR. WILLIAM M. POLK, IN THE CHAIR.

THE meeting was under the auspices of the Section on Genitourinary Surgery.

Local Anesthesia in Relation to the Surgery of the Genitourinary Tract.—Dr. JAMES F. MITCHELL of Washington, D. C., presented this paper. He declared that as New York was the cradle of local anesthesia he could not resist the temptation to wander into history and to recall the beginnings of modern local anesthesia. In the MEDICAL RECORD of September 19, 1884, there appeared a letter from Dr. H. D. Noyer of New York giving a report of the Ophthalmological Congress which had just concluded its session at Heidelberg, in which it was stated that the most important feature of the meeting was the demonstration of the anesthetic action of cocaine. Immediately the suggestion was adopted in New York, and as early as October 14, 1884, only a month later, the MEDICAL RECORD and other journals were fairly flooded with the reports of successful operations under cocaine by New York ophthalmologists Dr. C. R. Agnew, Dr. W. O. Moore, Dr. Mittendorf, Dr. James L. Minor, and others. In December, 1884, the first enucleation of the eye under cocaine was reported in the MEDICAL RECORD by Hazen of Youngstown, Ohio. New York surgeons were as active as the ophthalmologists and soon demonstrated the importance of intradermal injections for anesthetizing the skin. Dr. Halstead first injected cocaine into a nerve trunk for the production of anesthesia in the course of its distribution, paving the way for the neuroregional method. In the same year Dr. Leonard Corning demonstrated how anesthesia might be prolonged by the application of a tourniquet, and suggested performing spinal injection. It was thus that within a year after the introduction of cocaine as an anesthetic New York investigators had established nearly all the underlying principles of local anesthesia. Another interesting historical fragment was a letter appearing in November, 1884, in which Dr. Samuel R. Percy stated that on November 5, 1857, he had read before the New York Academy of Medicine a paper describing a substance which he had isolated from erythroxylon coca, and which he called "erythroxylene," identical with cocaine. Both the paper and the sample of the substance were accidentally lost. His report antedated that of Niemann's discovery of cocaine by three years. In the advanced and highly developed genitourinary surgery of to-day both local and spinal anesthesia had a definite place and their employment might convert many a bad risk into a safe operative case. Unfortunately, many of the accidents and deaths from local anesthesia had come from the genitourinary department; hence, a word of warning was in order. Haste and strong solutions must be avoided. Weak solutions and a little more time would give just as satisfactory anesthesia with a minimum of risk. If cocaine was used at all it should not be used in a stronger than 1 per cent. solution in the urethra, or 1/10 per cent. in the bladder, or for tissue injection, and always should be protected by adrenalin. Novocaine did not seem to be as effective as cocaine when applied to mucous membranes. Alypin was recommended as the most satisfactory cocaine substitute in the urethra and bladder. The use of too strong solutions was responsible for most of the accidents reported from the employment of this agent. The solution of alypin should not be above 1 per cent. combined with suprarenin for urethral injection. For injection into the tissues novocaine in ¼ to ½ per cent. solution combined with suprarenin was the only drug to be considered where any amount was necessary. Enormous amounts (250 to 300 c.c.) of this solution might be used. For nerve blocking this might be increased to 1 or 2 per cent. The whole penis as well as the scrotum and its contents might be readily anesthetized by basal injections permitting painless plastic operations, castration, or Hagner's operative treatment of epididymitis. General or even spinal anesthesia for such simple affairs was unnecessary. External urethrotomy was quite satisfactorily done in most instances by means of diffuse perineal injection with ½ per cent. novocaine and suprarenin. Where a more extensive field of anesthesia was required parasacral or spinal anesthesia might be more satisfactory. Even the inflamed bladder could usually be anesthetized by first washing it as clean as possible and then filling it with ½ per cent. alypin and suprarenin. After a few minutes it would be found to relax and more fluid would be admitted, so that after twenty or thirty minutes the bladder would permit such manipulations as cystoscopy or ureteral catheterization. Suprapubic cystotomy for the removal of stones and other purposes might be accomplished by the above procedure with the addition of a diffuse infiltration of the abdominal wall in the line of the incision. For more extensive operations one might resort to spinal or paravertebral anesthesia. It was especially in patients requiring prostatectomy or various operations on the kidney that those conditions were found which made it desirable to avoid general anesthesia. After a survey of the subject of prostatectomy Dr. Mitchell stated that if the safety of spinal anesthesia was admitted it was undoubtedly an ideal method. If spinal anesthesia was not to be considered, paravertebral, regional, or true local infiltration anesthesia offered a safe means of performing prostatectomy. Paravertebral blocking was an extremely serviceable method, capable of great variations, serving alike for thoracic, abdominal, pelvic, or perineal operations. The nerves were blocked just after emerging from the spinal canal, the particular ones varying with the site of the operation. Each nerve was reached by a separate needle puncture 4 cm. from the middle line at the level of the tip of a spinous process. The needle was held perpendicular to the skin surface and was pushed straight in until its point struck a rib, or in the lumbar region a transverse process. The needle was then moved until its point slipped over the lower border of the rib, when its projecting end was tilted outward 20 to 25 degrees. In this position it was introduced 1½ to 2½ cm. deeper. The injection was then begun and continued as the needle was withdrawn until its point reached the edge of the rib, by which time 15 c.c. of ½ per cent. novocaine with suprarenin had been introduced. This needle was left in as a guide to the introduction of the next. Anesthesia appeared in from fifteen to twenty minutes. The sacral nerves were reached through a point 1½ to 2 cm. to either side of the tip of the coccyx. A needle 12 or 15 cm. long was introduced, and the lower edge of the sacrum felt with its point. It was then pushed on parallel with the midline until it met obstruction, usually at a depth of 7 or 8 cm., which marked the sacral foramen. Here 25 c.c. of a solution ½ per cent. novocaine with suprarenin was injected. As the needle was withdrawn 35 cm. more were injected before the lower sacral border was reached, thus surrounding the third, fourth, and fifth nerves. The needle was reinserted, pointed a little more abdominally, and pushed up till obstruction was again encountered. Here again 40 c.c. were inserted. This was the safest form of local anesthesia by which the more complicated genitourinary operations might be accomplished. It was absolutely free from danger and apparently had no contraindications and had proven most satisfactory in the hands of Braun and other European surgeons. The author stated clearly that he did not advocate local anesthesia as a method of supplanting general anesthesia in all genitourinary surgery or any other branch of surgery. For handicapped individuals, bad surgical risks, the methods which had been discussed offered an extra protection and a possible means of rendering necessary surgical aid.

General Anesthesia, with Special Reference to the Surgery of the Genitourinary Tract.—Dr. JAMES TAYLOE GWATHMEY read this paper in which he first reviewed inhalation anesthetics and the methods of their administration in common use, and stated the general principles underlying them. He said that it should be borne in mind that the standards of a few years ago were not the standards of to-day, and that no anesthetic or method of administration should be tolerated that was not both safe and pleasant. Dr. Gwathmey then reviewed the statistics of the committee on anesthesia of the American Medical Association embracing the period from 1905 to 1912 inclusive. These statistics showed that 386 hospitals reported a total of 488,886 anesthesias, with a mortality of one in 4,404 cases. This small mortality meant that death from anesthesia resulted only through carelessness, ignorance, or useless experimentation with new methods before they were thoroughly understood or tested in the laboratories. The American statistics gave the mortality for ether as one death in 4,500, and for chloroform one death in 1,600, showing that ether was approximately over three times as safe as chloroform. These same

statistics showed that the nitrous-oxide-ether sequence was safer than the ether alone—only one death in 6,800 administrations. The chloroform-ether sequence was one of the safest methods of administering ether, only one death occurring in over 10,000 cases. Local anesthesia had no mortality in over 30,000 administrations. Deaths had, however, occurred under local anesthesia when the patient had not been properly prepared. Ethylchloride was a very safe anesthetic for short operations, no death being reported in over 12,000 administrations. The ethylchloride-ether sequence had presumably fallen into careless hands, since one death was reported in 2,590 cases. The writer stated that there was no special reason for using endotracheal anesthesia in surgery of the genitourinary tract. The safety of this method, now that it was understood, had been demonstrated beyond all peradventure by Elsberg at Mount Sinai and Peck at Roosevelt Hospital. The endopharyngeal method, however, was far superior as a routine practice. Intravenous anesthesia was a perfectly safe method if the technique of Dr. Honan was followed, that was, the introduction of the needle into the vein was the work of the surgeon, the anesthetist regulating the plane of anesthesia as with any other method. Oil-ether colonic anesthesia was not especially indicated in genitourinary surgery on account of the proximity of the anesthetic to this tract, since these organs were not any more affected by the anesthetic than the brain and other parts of the body. It was a perfectly safe procedure, however, and offered many positive advantages for those who knew how to use it. In speaking of anesthetics suitable for special cases, Dr. Gwathmey stated that young adults required some preliminary medication as well as older persons. Many more short operations could be satisfactorily performed in the doctor's office or in the patient's home than was now customary. For instance, the stretching of the sphincter ani, cystoscopy, fulguration of bladder tumors, urethral catheterization in irritable bladders, etc., could all be done with nitrous oxide and oxygen alone, and without any preliminary medication. After-pain could be averted in many of these cases by the continuance of the anesthetic for five minutes after the completion of the operation. Where very great subsequent pain was anticipated, the hypnotic should be administered before the anesthetic. Ether should not be used in these short operations. For circumcision and similar operations on young children, warmed ether vapor was usually to be preferred. For a child six years of age or older, gas and oxygen were entirely satisfactory. Straight ether should not be used with infants and children. Prostatic cases should all have the benefit of the preliminary treatment outlined by Crile and Buckler. Other patients, especially thin and emaciated ones, could be satisfactorily anesthetized with nitrous oxide and oxygen, without the addition of even small quantities of ether, provided proper preliminary medication had been given. A pint of tap water with one ounce of glucose, one ounce of soda bicarbonate, and one ounce of olive oil, given immediately before the patient left the table, was a good procedure for these patients. For prolonged and radical operations the patient should have more than the usual amount of preliminary morphine, and then only enough nitrous oxide and oxygen to secure unconsciousness would be required to complete the surgical operation. The writer offered the following conclusions: (1) Most patients to be anesthetized, either locally or generally, should have the benefit of physiological doses of morphine before anesthesia, and also of an alkali and carbohydrate treatment both before and after operation. (2) For very weak and feeble patients, for those in the extremes of life, or where exhaustion with acidosis was present, also when the patient was in a state of coma or had acute or subacute nephritis, or any respiratory affection, the morphine should be omitted and bromides, or paraldehyde and olive oil per rectum should be substituted. (3) The essence of orange-chloroform-ether sequence, or the nitrous-oxide-oxygen-ether sequence should be used instead of ether by the drop method or the gas-ether sequence. (4) Chloroform throughout was the anesthetic of choice for chronic alcoholics. (5) Oil-ether colonic anesthesia was indicated for the very obese. (6) For office work and short operations, it was both safe and satisfactory to use only nitrous oxide and oxygen, without any preliminary medication or the addition of ether. (7) For major operations in genitourinary surgery patients could be safely and satisfactorily narcotized with nitrous oxide and oxygen alone.

Dr. JOHN A. BODINE said that the question of anesthesia had always appealed to him. Its proper use carried with it no death rate immediate or remote and its proper application in its proper place made operation as painless as did the use of general narcosis. Cocaine was their first practical local anesthetic and none of the many substitutes offered were worthy of mention except its present rival novocaine. It was at first taken up by the profession with great enthusiasm, was used unwisely, and in the subsequent reaction almost discredited and dropped. The medical journals contained reports of alarming symptoms and even fatal results in each issue until cocaine was looked upon as more dangerous than general anesthesia. The daily papers taught the people exaggerated ideas of its dangers. This belief had not entirely disappeared. A very great misfortune would have fallen upon surgery had not a few men, prominent among whom were the readers of the papers, who believed in the desirability of a safe and efficient local anesthetic. Men had worked out the great principle of safety in the use of cocaine, viz.: "It is not the amount of the drug, within limits, that produces the toxic symptoms but the degree of concentration of the solution used—or the rapidity of its absorption." Thus two grains of cocaine in a 10 per cent. solution quickly injected would, in his opinion, be dangerous, in fact too dangerous to use, while even a greater amount could be used with perfect safety in a 1 to 500 solution. The use of cocaine had a bad start, being largely used in 4 per cent. solution and even stronger; it took a long time to convince the profession that 1/50 of 1 per cent. or 1 to 500 solution would benumb a sensory nerve beyond all perception of pain. A 10 per cent. solution could do no more. It was never necessary in general surgery, under any circumstances, to use a 4, 2, 1, or even ½ of 1 per cent. solution intradermically. Of these solutions 2 per cent. anesthetized the nerve but the balance went to poison the patient. This was the second great practical principle that made for safe and efficient work. A third factor of inestimable value by Corning, namely, that interruption of the circulation by elastic constriction prolonged and intensified the analgesia, and what Corning's discovery was to the extremities where it could only be used, Takanime's adrenalin was to the body as a whole; both acted alike. Intelligent comprehension of this trinity of principles plus acquirement of the art by practice permitted one to do almost any operation in surgery and that without pain and with safety. It seemed to him safe to say that 50 per cent. of the operations in a general surgical clinic could be done painlessly with this solution and a higher percentage of the operations in urology. Though he had largely abandoned cocaine in his work for novocaine the former had some advantages. It gave a more intense analgesia and was so quick in action that the knife could immediately follow its introduction. Above all it in no way impaired the well being of the wound. In over one thousand inguinal herniæ operations done under local cocaine analgesia not one wound suffered deep or defeating suppuration. In the beginning of their change from cocaine to novocaine they had some instances of necrosis in the skin. This tissue necrosis frequently followed other substitutes of cocaine that were quickly abandoned. It probably had much to do with isotonicity. All local intradermic analgesia must be isotonic with the blood serum, *i.e.*, have the same specific gravity and the same freezing point to obtain perfect results. After all cocaine was a poison and so was novocaine, only much less so. As novocaine and adrenalin gave a perfectly painless analgesia they gave up cocaine with regrets. At the beginning of operations patients at times showed a set of symptoms among the most prominent of which were thirst, rapid pulse, shallow and quickened respiration, facial pallor, and facial sweating. For a long time it had seemed to the speaker that these manifestations were due to cocaine toxicity, possibly an idiosyncrasy of certain patients. By chance he observed that the brother of a patient who was watching the operation also had these symptoms. They were largely psychical and needed no treatment nor did they interfere with the operation. They would occur if water was used as the anesthetic. The preliminary dose of morphine tended to avoid the annoying manifestations and was thus doubly valuable. In speaking of the technique Dr. Bodine said that gentleness in tissue handling came first. The personal demeanor, calmness, and assuredness of the operator found instant reflection in the patient. The position of the patient must not be a strained one. The table must

be soft and comfortable. If the patient once became restless he was lost so far as perfect analgesia was concerned. Above all things it was a mistake to have someone to try to occupy the mind and attention of the patient. A moral anesthetizer failed to be a convincing persuader. It was best to perform this part oneself. One heard much of suitable patients, that some bore pain well and were thus good patients for local anesthesia, that others were difficult; there was not much in this in their experience. They had taken their one thousand cases of herniæ just as they came, the nervous and the phlegmatic, and not one had manifested sufficient pain to cause him to move hand or foot. The claim of increased postoperative pain had not been their experience. In the special field of urological surgery the speaker said that it seemed to him that all renal surgery demanded general anesthesia because large powerful muscles must be retracted and local anesthesia did not always produce relaxation. All ureteral surgery likewise demanded cerebral narcosis. As to the bladder, such operations as high drainage or cystotomy, uncomplicated stone, or pedunculated papilloma, local anesthesia should be the choice, while malignancy and prostatectomy required general sleep. The bladder mucosa should be anesthetized with large quantities of weak solution, giving time for the effect to intensify, and never with small quantities of strong solution. All surgery of the external generative organs could be satisfactorily accomplished under local anesthesia, from circumcision to castration. Each operation required its special technique according to the neural anatomy. This must be understood as a fundamental. Local anesthesia by infiltration had no place in either general or urological surgery in an inflamed septic area. To open a felon on the finger, or a carbuncle on the neck, a cellulitis of the perineum, or a foreskin by infiltrating cocaine into the area seemed like subverting the foundation principles of surgery.

Dr. Edward L. Keyes, Jr., considered the temperamental side of the subject and referred to what had been brought out at the recent Congress in Berlin and was pleased to learn that this was in accord with the views expressed by Dr. Cabot. There was much fear shown by patients about to undergo operations under local anesthesia. Yet it was to be remembered that some surgeons could not do little things but they could do big things under local anesthesia. Local anesthesia did not appeal to Dr. Keyes as an agent of choice. In operations, for instance, for epididymitis one could push the anesthetic too far and with bad results. In non-inflammatory operations on the scrotum, local anesthesia was to be preferred, but in the inflammatory conditions he did not like local anesthesia.

Dr. Martin W. Ware did not believe that local anesthesia had any place in genitourinary surgery as a rule. Fifteen years ago the Medical Society of the County of New York had a meeting in which a surgeon stated he did not believe that cocaine was any anesthetic whatsoever and he gave as his opinion "because the patient was one-half the time on the table and one-half the time off the table howling." But a little coaxing made the patient all right. At present Dr. Ware used novocaine. He said he had abandoned local anesthesia in circumcisions in adults.

Stated Meeting, Held November 5, 1914.

The President, Dr. William M. Polk, in the Chair.

This was the occasion of the annual meeting of the New England Pediatric Society, the Philadelphia Pediatric Society, and the Section on Pediatrics of the New York Academy of Medicine. The visiting physicians spent the morning inspecting the new building of the Department of Health and the exhibit of the Bureau of Child Hygiene, the exhibit of the New York Milk Committee, and the Research, Antitoxin, and Vaccine Laboratories of the Department of Health, where demonstrations of the Negri bodies and trachoma was given by Dr. Anna M. Williams and of the Schick reaction by Dr. Park and Dr. Zingher. In the afternoon a visit was made to the Children's Wards of the Presbyterian Hospital and to the Rockefeller Institute, and Dr. Holt held a clinic at the Babies' Hospital.

Experimental and Clinical Studies in Hemolytic Jaundice, with Special Reference to the Effects of Splenectomy.—Dr. Edward B. Krumbhaar of Philadelphia presented this communication, in which he first described the experiments of Dr. Pearce, himself, and other colleagues which had been carried on for the past three years at the Research Laboratory of the University of Pennsylvania, after which he discussed the bearing of this experimental work on the clinical aspects of the various types of splenomegaly with anemia. He said that although they at first were concerned with the relation of the spleen to hemolytic jaundice, they soon found themselves confronted with the broader problem of the relation of the spleen to blood formation and destruction in general. This study had brought out many explainable facts and some that were apparently paradoxical. Their first experiments confirmed and elaborated the earlier observations of Banti and Joannovics that it was more difficult to produce jaundice by means of hemolytic serum in splenectomized than in normal dogs. Attempts to explain the cause of this phenomenon, which was directly related to clinical splenectomy for the cure of various conditions associated with hemolytic jaundice, led them to study the blood changes following splenectomy. They found that anemia always developed, reaching its maximum about the third week and reaching normal in about ten months. Pearce, Karsner and Peet found that the resistance of the red cells was increased after splenectomy both to hypotonic salt solution and to immune serum. Austin noticed that the greatest resistance to jaundice occurred at the same time as the greatest anemia developed and to test the connection between the two gave hemolytic serum to animals made anemic in other ways. He had found this same resistance and had concluded that the phenomena was partly due to the more resistant erythrocytes, and partly to the fact that less blood was destroyed because there was less blood present to be destroyed. In testing the blood forming powers of the spleen by comparing the blood going to and that coming from it, some authorities claimed to have found more red cells, white cells, and hemoglobin in the splenic vein. Their experiments along these lines were negative, and it seemed that in spite of evidence of occasional myeloid metaplasia in the spleen they must accept the dictum that the red cells at least were formed only in the blood marrow. Asher and his pupils had offered as an explanation of the anemia that followed splenectomy that increased amounts of iron were lost through the stools; but here, again, their experiments failed to confirm such an explanation; they did find, however, that injection of splenic extracts intraperitoneally had a marked temporary effect in raising the count of erythrocytes, hemoglobin, and leucocytes, presumably due to stimulation of the bone marrow.

A possible explanation of the anemias following splenectomy, was, therefore, that the bone marrow was deprived of a stimulating hormone. Explanation of the recovery from anemia might also be found in that the lymph nodes were found enlarged after splenectomy and presumably had taken over some of the function of the spleen. Pearce and Pepper had found that bone marrow in splenectomized dogs frequently showed signs of active regeneration at the periods when the anemia was being recovered from. Although splenectomized dogs showed less tendency to jaundice when hemolytic agents were administered, nevertheless such agents caused a greater fall in blood counts, a more lasting damage, and a greater fragility of the red cells than in normal dogs. Apparently the lessened tendency to jaundice was connected in some way with the anemia caused by splenectomy, while the lessened power to recover from the hemolytic anemia must be attributed to the loss of some specific substance from the spleen. Banti had brought forth evidence of special hemolytic activity of the splenic extracts and of dissociated hemoglobin in the splenic vein, but their observations had failed to substantiate these claims. Joannovics and Pick had shown that chronic toluylendiamin poisoning caused fatty changes in the liver with liberation of unsaturated fatty acids, and Eppinger and King had shown that after splenectomy the amount of blood fat and cholesterin rose and the iodin number (combining value of the unsaturated fatty acids) of the blood dropped, indicating lessened degrees of hemolysis. In clinical conditions associated with blood destruction, they also found an abnormally high iodin number and this was reduced after the case had been improved by splenectomy. The unsaturated fatty acids were well known as hemolytic agents and the lessened blood destruction after splenectomy might thus be explained. The speaker then gave a review of the history and a detailed description of the different types of primary splenomegally with anemia, namely, Gaucher's, Banti's, von Jaksch's, and the two types of

hemolytic jaundice, the Hayem-Widal, or acquired form, and the Chauffard-Minkowski, or congenital or hereditary form. Gaucher's disease had but little in common with the other types of splenic anemia, and though the negative character of the symptoms might cause it to be confused with Banti's disease, pathological examination should admit of a proper differential diagnosis. After describing the symptomatology of Banti's disease the writer stated that although the etiology of the disease was unknown, evidence pointed to the close causative relationship of the spleen. One would not expect the removal of a largely fibrotic organ to be attended with marked somatic changes and it was precisely in the earlier stages of the disease in which splenectomy had proven most beneficial. The anemia infantum pseudoleucemica of von Jaksch was in all probability not an independent condition but represented an atypical response of the infantile hemopoietical system to one or other of the primary diseases of the blood. The acquired and congenital types of hemolytic jaundice with splenomegally (Hayem-Widal and Chauffard-Minkowski) possessed rather characteristic differences and he deemed it advisable to follow the Continental custom and consider them as independent conditions. In the congenital type the resistance of the red blood cells to hypotonic salt solution was much diminished and this furnished a simple differential test, the technique of which was described by the speaker.

The cardinal symptoms of these types of hemolytic jaundice with splenomegaly were a chronic enlargement of the spleen, existing with an acholuric, non-obstructive jaundice, and anemia, frequently paroxysmal in character and varying in intensity. Increased blood destruction was indicated by increased urobilin in the urine, and various characteristic changes were found in the blood, the red cells showing diminished resistance to hypotonic salt solution, there being an increased number of reticulated cells with vital staining, and in the acquired form the phenomenon of autoagglutination, of the red corpuscles. In the congenital form the subjects were often more icteric than sick, while the acquired form was usually ushered in with a definite attack of illness, the anemia became more grave, and the patient was distinctly more anemic than jaundiced. The congenital or familial form appeared to be more of an inherited dystrophy of the hemopoietic system, rendering the red blood cells more easily destructible. In discussing the morbid anatomy in hemolytic jaundice, the author said he had collected eight autopsies and seven splenectomies which showed chiefly congestion of the spleen, especially of the pulp cords, with increased pigment and macrophages. After reviewing the various ineffectual therapeutic measures that had been tried in these conditions, he stated that splenectomy seemed to offer the most hope for improvement or cure and should be considered, with due regard to conservatism, in all these diseases in which there was evidence of increased blood destruction referable to the spleen. In early Banti's disease and hemolytic jaundice, at least, the results had been excellent. In pernicious anemia, although improvement had followed in some cases, the value of splenectomy was more dubious and this grave operation should only be tried where the indications were clear and other methods had proved unavailable.

Acute Acid Intoxication in Infants and Children: A Study of 100 Consecutive Cases in Apparently Epidemic Form.—Dr. CARLETON R. METCALF of Concord, N. H., presented this report of an epidemic which occurred last winter at Concord, N. H. There were in all 200 cases, with nine fatalities. The report presented consisted of 100 tabulated cases. The author considers the bearing of such etiological features as age, environment, milk, water, diet, and neurotic temperament, none of which nor all together seemed to account for the outbreak. The tabulated report showed the frequency of such symptoms as diarrhea, vomiting, wasting, retracted abdomen, abdominal pain, icterus, etc. He also described the stools, vomitus, and urine. The treatment consisted chiefly in dietetic measures and in the administration of soda and the citrates. The author also discussed the source of the acetone bodies and their relation to autointoxication.

The Occurrence and Significance of Melliturin in Infants Suffering from Nutritional Disorders.—Dr. OSCAR M. SCHLOSS presented this paper, which concerned primarily the nature and significance of the reducing substance which commonly appeared in the urine of infants affected with nutritional disorders. Sugar which was used in metabolism was carried by the general circulation and it was obvious that sugar which appeared in the urine was derived from the blood sugar. Recent work had shown that normal blood sugar in infants ranged from 0.07 to 0.11 per cent., figures which were practically identical with those which obtained for adults. Although there was a tendency for the blood sugar to maintain a constant level, striking changes might occur following the ingestion of carbohydrate food. There was often a definite increase in the blood sugar shortly after a meal which reached its maximum in from one and one-half to two and one-half hours and then decreased. This increase might be effected by starch as well as sugar, though the rate of increase was slower and to a lesser degree. Owing to this fact the blood for examination was usually withdrawn about three and one-half hours after a meal. Dr. Schloss stated that there was a direct relationship between increased blood sugar and melliturin. As a rule, a continued increase in blood sugar led to an excretion of sugar in the urine, although this effect might not be immediate. Often the hyperglycemia might precede the melliturin for some time. A detailed consideration of the significance of increased blood sugar could be of little benefit, for despite the great amount of work done in the mobilization and utilization of sugar, especially in diabetes, there were many essential factors which were unknown or were still under discussion.

It seemed safe, however, to assume that hyperglycemia meant a disturbance in the balance between mobilization and consumption of sugar and often signified a decreased power of burning sugar, provided that the patient was afebrile and the diet normal. The detection of a reducing substance in the urine of infants affected with gastroenteric disorders was by no means recent. Most of the earlier writers considered that the sugar was lactose derived from the food. Langstein and Steinitz found galactose in addition to lactose in fourteen out of thirty-eight cases of melliturin. Luzzato also found galactose in the urine of infants. Finkelstein and Meyer were led to attach great importance to the melliturin in nutritional disorders. They divided the cases into two groups: 1. Those in which the appearance of lactose in the urine was considered as indicative of an intestinal lesion through which lactose was absorbed before it was split by the inverting enzyme of the intestinal secretion. 2. When galactose was found tin the urine and it was thought that the underlying cause was a diminished sugar tolerance, the liver probably being at fault. Dr. Schloss' work comprised the study of the blood and urine of 235 infants. The preliminary tests of the urine were made by the reagents of Benedict and Nylander, and if the reducing substance was present in sufficient quantity further tests were carried out to determine its nature. There were 40 normal infants whose blood sugar ranged from 0.068 to 0.11 per cent. All were free from digestive disturbances and none showed the presence of sugar in the urine. The remaining 195 cases represented nutritional disorders ranging from the milder disturbances and dyspepsia to those of severe intoxication. For convenience the cases were roughly divided into three groups: mild, moderate, and severe. The speaker demonstrated by means of charts that there was an association between the increased blood sugar and the presence of sugar in the urine. As a rule the cases with melliturin showed hyperglycemia. The next question considered was the nature of the sugar in the urine. In most instances the percentage ranged from 0.05 to 0.1 per cent. In such cases a determination of its nature with any degree of accuracy was impossible. In 27 cases the urine at some time contained one per cent. or more of sugar and further tests were made to determine its nature. These examinations were shown in tabulated form, which demonstrated that the sugar was usually galactose or dextrose. Lactose occurred, but not alone, for it was always associated with more or less galactose.

The important facts brought out were: 1. Melliturin was usually accompanied by an increase in blood sugar. 2. The sugar in the urine was a monosaccharide. These results indicated that a gross lesion of the intestine was not a direct cause of the melliturin, but indicated strongly that the direct cause was a lowered tolerance to sugar. To definitely determine this tolerance tests were made on normal infants and others affected with nutritional disorders. The results showed definitely that there was a lowered tolerance to sugar in the nutritional disorders.

Pathological Society of Philadelphia.

At a stated meeting held November 12 Drs. John B. Deaver and George M. Dorrance presented a specimen of "Gigantic Duodenum due to Kinking at a Gastroduodenostomy Opening, Associated with Dilatation of the First Portion of the Jejunum and a Fistula from the Jejunum into the Transverse Colon." The patient was a man who in 1908 came under treatment for symptoms of duodenal ulcer and for the relief of which gastroenterostomy was performed. Several years later, symptoms of duodenal perforation developed, and the lesion was exposed and closed by suture. A similar accident occurred at a still later period, and again relief was afforded by suture. The patient, however, was eventually seized with vomiting and the passage soon after ingestion of undigested food, and death resulted from inanition. Post-mortem examination disclosed a patulous pylorus, with the first part of the duodenum greatly distended in consequence of the presence of a constricting band of mesocolon, and beyond this the duodenum was distended to enormous proportions. In addition to the communication established between the stomach and the intestine as a result of the operation, there was also an adventitious communication between the jejunum and the transverse colon established as a result of perforation with protective adhesions.

Dr. F. D. Weidman presented "A Penicillium (Species?) Superimposed Upon a Tuberculous Peritonitis and Pleurisy." The patient had an ulcerative tuberculosis of the lungs, with involvement of the pleura, and also tuberculosis of the bowel, with involvement of the peritoneum. The growth of penicillium was found upon and within the proliferation on the pleura and the peritoneum. It was concluded that the contamination had taken place during life.

Dr. George W. Outerbridge presented a specimen of "Chorionepithelioma with Intraperitoneal Hemorrhage." The patient was a young woman who was curetted following what was thought to be a miscarriage, but which in reality was the expulsion of an hydatidiform mole. After a while, menstruation set in, and after being repeated a number of times it remained in abeyance, and it was thought the patient was pregnant. Later, slight hemorrhage recurred. Finally, the patient was seized with severe abdominal pain and signs of shock with profound anemia. Extrauterine pregnancy being suspected abdominal section was performed and the cavity found filled with a large amount of fluid and clotted blood. Supravaginal amputation of the uterus with the appendages was undertaken, the patient was transfused with saline solution and after a slow and steady improvement she left the hospital after three weeks. The uterus proved to be the seat of an intramural chorionepithelioma, one portion of which had penetrated the wall of the uterus and ruptured into the peritoneal, with the resulting hemorrhage. The cavity of the uterus was not at all invaded by the growth, and this fact accounts for the absence of external hemorrhage.

Dr. A. H. Hopkins presented a communication entitled "Studies in the Concentration of Blood-sugar in Health and Disease."

Drs. C. J. Swalm and A. W. Mann presented a communication entitled "Colloidal Gold Test of Cerebrospinal Fluid in Paresis and Other Mental Conditions." They found among other things that the reaction of the cerebrospinal fluid to the colloidal gold test was positive in a number of cases of tabes and paresis when other diagnostic tests were negative.

Erythromelalgia.—E. G. G. Little reports the case of an elderly woman with an eruption on the hands and feet, which he regards as possibly of the same class as some cases which have been described as erythromelalgia. The patient had had for some two years a pronounced redness of the palms and soles, accompanied by considerable tenderness and pain in these parts. The color was a vivid pink, and extended over the whole palm and slightly on to the flexor surface of the wrist, in between the fingers and along their inner and outer surfaces nearly to the dorsal aspect, and covered the whole plantar surface of the feet. There had never been any exudation or exfoliation, and the symptoms had persisted unchanged during the five weeks that the patient had been under observation. She had no treatment, either local or general, and had not taken any drugs which could account for the symptoms. She appeared otherwise in fair health.—*Proceedings of the Royal Society of Medicine.*

Miscellany.

Work in a Field Hospital.—As described by Tugendreich in the *Deutsche medizinische Wochenschrift* for October 29, the order was finally received after numerous long marches to set up a field hospital. The command, who had had no sleep the night before, were about to proceed with this task, when the seemingly friendly natives began to snipe and kept up their fire through the night. Houses from which proceeded the shots were at once set on fire and all civilian men taken as hostages. In the meantime news of a violent engagement was received and the surgeon of the command ordered the medical personnel to move up to the dressing stations. Their arrival on horseback was timely and three hundred wounded were at once carried back to the field hospital, which by this time was ready to receive them. Dressing went ahead for hours until some time for sleep was afforded. In the meantime the order came to dispatch the wounded homewards and break up the field hospital for another forward move. All the munitions were at once packed in the ten wagons in readiness to march when the program was quickly changed as the result of a night battle, in which many were wounded. There was a local hospital connected with a school, but all the personnel had gone. The Germans took over the management and all wounded were treated alike—Germans, French and English. There was work enough for all. A slightly wounded English major passed the time by knitting stockings.

A Versatile Benefactor of Mankind.—The subject of this sketch is claimed equally by chemistry, biology, medicine, industry, agriculture, and economics, and all are deeply indebted to him for substantial scientific contributions. Chemistry is his debtor for throwing a flood of light on the nature of isomerism, and thereby laying a secure foundation for our present conception of structural chemistry. Biology is his debtor for effectively disposing of the theory of spontaneous generation and for demonstrating fermentation as a vital phenomenon. Medicine is his debtor for establishing the relation of bacteria to disease, and for fundamental contribution to the science and practice of immunity. Agriculture is debtor for his brilliant work in devising a protective vaccine against anthrax, a dread scourge of cattle and sheep. Industry is his debtor for epoch-making discoveries in fermentation which provided a badly-needed scientific foundation for the wine industry, and for his work in discovering the cause of the silk-worm blight whose control saved the silk industry in France from destruction. Economics is his debtor for the knowledge which made possible the introduction of canned goods, a step which has wrought profound economic changes throughout the world. With all the world so largely his debtor, let us revere the name of Louis Pasteur, benefactor of mankind.—*Weekly Bulletin of the Department of Health of New York City.*

A Schedule of Fees.—The physicians of Hancock County, Ind., have recently adopted a new scale of fees. The minimum charge for an office consultation is 50 cents and for visits to the patient's home the charge varies from $1.50 for a distance of one mile or less to $4.00 for a distance of nine miles; for night calls an additional 50 cents is charged. The fees for surgical operations vary from $5.00 to $200.00.

Abbe, R., a case of sigmoid diverticulitis simulating malignancy, demonstrated by radiograph; operation and specimen, 190; radium beta rays, the efficient factor in repressive action on vital cells, 909; the present estimate of the value of radium in surgery, 279.

Abderhalden reaction, 692, 771, 1023; and syphilis, 270; and *x*-rayed organs, 930; dialyzer for, 389; in cancer, 681; in carcinoma, 943; in pregnancy, 67, 942; in pregnancy and cancer, 309, 560; specific ferments against bacteria, as detected by, 942; with normal and pathological serums, 900.

Abdomen, acute pain in, due to accessory spleen, 937; cutaneous reflexes of, 400; disorders of, cecum in, 980; distention of, 692; hemorrhage of, complicating normal pregnancy, 979; incision of, 522; left-sided pain in, abdominal aneurysm as cause of, 528, 587; operations on, 171; pain in penetrating wounds of, 86; treatment of bullet wounds of, 676; wall of, abscess of, 92.

Abelin reaction in syphilities treated with salvarsan, 37.

Abortion, icterus following, 159; revocation of license for, 633; sepsis following, 92.

Abrams, A., Abrams' method of treatment in aneurysms, 549.

Abscess, cerebellar, 360, 525; large abdominal, 92; lung, 680; retropharyngeal, 1009.

Accident, and disease in life insurance, 773; and mental defects, 14; cases, railway, neurological aspects of, 706; traffic, 73.

Achlorhydria and achylia gastrica, 527.

Achylia, gastrica and achlorhydria, 527; gastrica and gastrogenic diarrhea, 1064; pancreas, and acute pancreatitis, 81.

Acid intoxication in infants, acute, 1107.

Acidosis, and nitrogen partition in pregnancy, 354; holding breath as index of, 261; terminating chronic myocardial disease, 30.

Actinomycosis, 939.

Adiposis and lipomatosis, 432.

Advertisements, illegal medical, 883.

Aerophagia, 78, 527; rectal, 722.

Aged, neglect of, 457.

Alberta, climate of, 176.

Albumin, in serous fluids, 161; in sputum, 783.

Alcohol, and engineer, 768; and tobacco, and life expectancy, 773; injections in coccygodynia, 322; injections in neuralgia, 936.

Alcoholism, as factor in disease, 666; neuroses of, periodicity of, 628.

Alopecia, areata, epidemic, 208; dental, 592; following severe impetigo of the scalp, 77; posttraumatic, 1094.

Amenorrhea, hypophysis extract in, 644; primitiva, 91.

American Medical Association, election of officers of, 23; reports of committees, 34.

Aminoaciduria and hepatic insufficiency, 205.

Aminoazobenzoles, epithelizing action of, 563.

Amputations, 702.

Amsden, H. H., Vincent's angina, 881.

Anaphylaxis, and apotoxin, poisoning of, 939; and skin reaction in hay-fever subjects, 891; autoserotherapy in shock of, 232; fever, and metabolism, 634.

Anemia, ankylostoma, treatment of, 215; in infancy, blood pressure in, 41; nerve deafness associated with, 766; pernicious, psychosis of, 559; pernicious, salvarsan treatment of, 37; pernicious, soreness of tongue and palate as early symptoms of, 349; pernicious, transfusion and splenectomy for, 860; spleen in, 430; splenectomy in treatment of, 355.

Anesthesia, chloroform, and cardiac fibrillation, 642; control of nausea following, 1051; dangers of, 395; general, in surgery of genitourinary tract, 891, 1104; in urology, 429; intratracheal, 505; intratracheal, emphysema following, 926; local, in genitourinary surgery, 1104; local, operations for inguinal hernia under, 540; local, thyroid operations under, 767; of larnyx, 30; of uterus, 263; oil-ether colonic, 582; paravertebral conduction, 263; presacral conduction, 429; spinal, in gynecology, 396.

Aneurysm, abdominal, as cause of left-sided abdominal pain, 528, 587; abdominal, treated by operation, 360; Abrams' method of treatment in, 549; of profunda femoris artery, 180; of aorta, causes of death in, 772.

Angina, pectoris, 179; ulcerative, in typhoid fever, 259; Vincent's, 881.

Anoci-association, 361; in operations on gall bladder and stomach, 85; in shockless operation, 561.

Anosmia and traumatic enophthalmus, 1102.

Anthrax, human, 939.

Anthropometric methods, 571.

Antibodies, lipoid, 636, 637.

Antigens, cholesterinized, 405; in Wassermann reaction, 260.

Antrum, empyema of, with infection of nose and cheeks, 488.

Anus, benign or doubtful tumors of, 77; fistula of, in life insurance, 82.

Aorta, aneurysm of, causes of death in, 772; disease of, and life insurance, 264.

Aphasia, extradural hemorrhage causing, 866.

Appendicectomy, relief of gas pains after, 892.

Appendicitis, acute, prognosis in, 680; and acute appendicular obstruction, 362; and general peritonitis, postoperative paralytic ileus, enterostomy in, 180; and worms, 563; chronic, colonic inflation in diagnosis of, 528; chronic, conditions simulating, 602; chronic, gastric ulcer, and duodenal ulcer, blood in, 133;

chronic or hysteroneurasthenia, 216; chronic, relation of movable kidney to, and to cecum mobile, 118; chronic, reflex disturbances in, 1077; microscopical traumatic lesions of mucosa found in, 915; mortality and morbidity of, 902; pelvic abscess following Fowler position in, 1029; pulmonary tuberculosis complicating, 601; suppurative, in pregnancy, 184.

Appendix, *x*-ray examination of, 259.

Arrow as weapon, 1061, 1062.

Arsenic eaters, 1011.

Arteries, calcification of, 217; disease of, and life insurance, 174; disease of, late manifestations of inherited syphilis in, 36; hypertension of, 17.

Arteriosclerosis, and nephritis, relation of arterial hypertension to, 17; and nephritis, blood pressure and pulse pressure in, 805; and life insurance, 564; of pulmonary arterial system, 44.

Artery, aberrant middle colic, internal hernia due to, 85; inferior mesenteric, occlusion of, 718; profunda femoris, aneurysm of, 180.

Arthritis, associated with lesions of genitourinary tract, 169; chronic, postural treatment of, 820; deformans and infective deforming arthritis, complement fixation tests in, 944; deformans, cultures from tissues and application in, 947; deformities of, surgery of, 360; infective deforming, complement fixation tests in, 944; obscure, treatment of, 767; origin of, 81; streptococcic, surgery of, 309.

Ascites, cardiac and nephritic, treatment of, 572; of hepatic cirrhosis, Lanz's operation for, 76.

Asthenia, periodic, 512; traumatic, and traumatic shock, 972.

Asthma, and emphysema, dead space and alveolar air in, 36; empirical remedy for, 186; in children and egg-poisoning, 891; nasal, experimental studies on, 122; operative treatment of, 641; treatment of, 232, 908.

Ataxia, acute cerebellar, 69; Friedreich's, tabes dorsalis suggestive of, 907.

Diarrhea, gastrogenic, 1064; treatment of, by anesthetization of stomach, 349; summer, 169.
Diathermic treatment, 1006.
Diet, and cancer, 699; and toxicity of substances acting on liver or kidney, 170; and transplantable sarcoma in rats, 649; blood, and blood vessels in infantile scurvy, 990; caramel, in diabetes, 216; for athletes and soldiers, accessory articles of, 816; high caloric, effect of, on fecal flora in typhoid fever, 444; high caloric, in typhoid fever in infants and young children, 485; in typhoid fever, 558; Karell, 255; of children during second period of life, 624; of sick infants, caloric value of, 568; rational, for typhoid fever, 579.
Digestion, of infant, influence of starch on, 40; parenteral, and immunity, 945.
Digestive tract, chronic diseases of, lymphocytosis as sign of constitutional derangement in, 527.
Digitalis, in chronic diseases of heart, 438, 475; tincture of, activity and stability of, 80.
Diphtheria, active immunization in, and treatment by toxin-antitoxin, 523; administrative control of, 211; antitoxin in treatment of pneumonia, 320; carriers, method of treatment for, 158; heart in, 1054; laryngeal, deferred death after tracheotomy for, 216; of skin, 308; polyneuritis in, 603; prophylaxis, 303.
Diplegia, spastic, 780.
Disease, alcoholism as factor in, 666; and accident in life insurance, 773; and dust, schoolroom, prevention of, 331; and patient, 1060; borderland of, 981, 1021; cause-nexus in, 1055; general, etiology of, focal infection in, 35; infectious and the alien, 28; obscure causes of, 775; prevention day, 638; reporting of, 311; treatment of, conservatism in, 199; common, in camp, 561; connected with Meckel's diverticulum, with special reference to diverticulitis, 570; contagious, proof of cause of, 297; deficiency, misconceptions regarding, 252; infectious, etiology of, 21; infectious, transmission of disinfection after, 657; nonsyphilitic, salvarsan in, 308; notable in New York City, 554; of unculture, extinction of, 603; organic, occupation therapy in, 346.
Disinfection, experiment in, 1055.
Dispensary, abuse, 460; function of, 474.
Diverticulitis, diseases connected with Meckel's diverticulum, with special reference to, 571; sigmoid, 224; sigmoid, simulating malignancy, 190.
Divorce, and insanity, 980; and mental defects, 14.
Doty, A. H., the means by which infectious diseases are transmitted and disinfection, 657.
Drugs, absorption of, 347; imported, shortage of, 895; scarcity of, owing to war, 470; used in general and mental hospitals, 641.
Duncan, C. H., autoimmunization in respiratory infections, 408.
Duodenum, alimentation via, 1069; and pylorus, obstruction of, 389; and pylorus, ulcer of, closure of pylorus for, 854; and small intestine, cancer of, 809, 814; and stomach, atony of, 817; and stomach, ulcer of, 898; and stomach, ulcer of, ruptured, 692; and stomach, ulcers of, diagnosis and treatment of, 95; and stomach, ulcer of, end results of cases of, 34; and stomach, ulcer of, occult hemorrhage in, 31; contents of, direct examination of, in gall-bladder and pancreatic affections, 527; enema of, in treatment of toxemia of pregnancy, 102; ulcer of, 81; ulcer of, demonstration of, by roentgen method, 528; ulcer of, gastric ulcer, and chronic appendicitis, difference of morphology of blood in, 133; ulcer of, *x*-ray recognition of, 31.
Durrah, F. F., recovery from bichloride of mercury poisoning, 844.
Dysentery, 560, 602, 683; amebic, in children, 39; amebic, treatment of, 1018; bacillary, among troops in Vera Cruz, 167; bacillary, saline treatment of, 168; emetine in, 124; treatment of, 982; vaccination against, 391.
Dysmenorrhea, treatment of, 232.
Dysparcunia and its surgical treatment, 30.
Dyspituritarism, preadolescent, 319.
Dystonia musculorum deformans, 1000.
Dystrophia adiposogenitalis, 31, 1028.

E

Ear, diseases, radium in, 376; middle, infection of, with *Bacillus tuberculosis* and *Bacillus coli*, 585; middle, suppuration of, diminished hearing after, 64; focal infection of, 892; suppuration and life insurance, 1103.
Eclampsia, abdominal cesarean section for, 397; conservative versus radical treatment of, 901; liver in, with extensive sucapular hemorrhage, 184; treatment of, by veratrine, 355.
Eczema, and neurodermatitis in childhood, 1062; in infancy and childhood, 1076.
Edema, congenital, 1061.
Education, dental, tendencies of, 385; in pediatrics and social medical work, 606; of public in medical matters, 123; public health, 418.
Egg poisoning and asthma, 891.
Ehrlich, S. D., a case of retroperitoneal and extensive subcutaneous emphysema following intratracheal anesthesia, with recovery, 926.
Einhorn, M., the diagnosis and treatment of gastric and duodenal ulcers, 95.
Elbow, joint fractures about, treatment of, 752; old injury to, 547.

Electricity, continuous static current of, 820; high-frequency, in treatment of bladder tumors, 771; high-frequency, in treatment of pellagra, 820; high-frequency, in treatment of pulmonary tuberculosis, 437; high-potential effect of, in treatment of gout, 820; in treatment of cancer, 651; in treatment of gastrointestinal affections, 828; shock of, hysterical brachial monoplegia following, 740; static, and apparatus, 819.
Elsberg, C. A., cyst of the cerebellopositive angle; operation with relief of symptoms, 1050.
Embolism, and thrombosis, in abdominal and pelvic surgery, 38; air, and insufflation of, bladder, 553.
Emphysema, and bronchial asthma, dead space and alveolar air in, 36; retroperitoneal and subcutaneous, following intratracheal anesthesia, 926.
Employee, liability for medical services to, 845; liability of department store for medical services rendered to, 633; liability of hospital for injuries to, 883.
Empyema, of antrum with infection of nose and cheeks, 488; meningococcic, 935.
Endocarditis, in children, 481; rheumatic, auricular flutter occurring during, 63; traumatic, 680.
Enophthalmos, traumatic, 1102.
Enterocolitis, membranous, charcoal in treatment of, 362.
Enterostomy, following appendicitis, with general peritonitis and postoperative paralytic ileus, 180.
Enuresis, 812.
Epigastrium, non-infected wounds of, delayed union in, 690.
Epilepsy, and tuberous sclerosis, 769; diagnosis of, 893; Jacksonian and idiopathic, 779; outlook in, 815.
Eppinger, H., intestinal intoxication, 363.
Erdmann, J. F., biliary surgery, 620.
Ereuthophobia (erythrophobia), 348.
Erysipelas, anemic, 31.
Erythema, infectiosum, 564; nodosum and tuberculosis, 728.
Erythromelalgia, 1108.
Esophagus, artificial, new method of forming, 76; atresia of, *x*-ray illustrations of, 739; resection of, for carcinoma, 530; spontaneous rupture of, 28.
Ethylhydrocuprein in treatment of ulcus corneæ serpens, 645.
Eugenics, 117, 141, 439; in Huntington's chorea, 103.
Evidence, as to improper removal of healthy tissue, 19; as to malpractice, 511; as to result of injuries, 845; expert, as to negligence, 674; insufficient, as to malpractice, 160; opinion, foundation for, 971; *x*-ray photographs as, 674.
Ewing, J., precancerous diseases and precancerous lesions, especially in the breast, 951.
Examinations, for life insurance, inadvisability of use of instruments in, 264; in life insurance, repeated, benefit of, 32; physical, periodical, 342; physical, simpler methods of, 1070; State Board, bulletin of, 950; thirty-one thousand medical, 770.
Examiners, chiropractic, how chosen, 251; medical, American Association of, election of officers of, 32; medical, work of, 128; medical, suggestions to, 82, 218, 264, 350, 435, 526, 646, 733, 818, 896, 983, 1065.
Exercise or rest, in treatment of pulmonary tuberculosis, 178; therapy, 819.
Expert, medical, examination of, 720; opinion merely advisory to jury, 883; qualification as, 845; quack as, 207.
Exophthalmic goiter, 955; and endemic goiter, 262; and tabes, interrelation of, 27; relations of thymus to, 310; treated with pituitary and thymus extracts, 75.
Eye, chronic tuberculosis of, 124; diseases, vaccine therapy in, 812; lesions in war, 1024; lesions of, due to atoxyl, 81; functional acuity of, 240; manifestations of, in toxemia of pregnancy, 124.

F

Face, hemiatrophy of, greatly improved by administration of thyroid extract, 906; left half of, congenital hypertrophy of, 738; protector and head-mirror combined, 971; to face, 877.
Fascia and fat transplantation, 253.
Fashions, and sex, 874.
Fat, absorption of, from intestinal tract of actively tuberculous child, 40; and fascia transplantation, 253; anisotropic, and its excretion, 847; low and high proteins in infant feeding, 568; swine, in infant feeding, 40.
Fatigue toxin and immunity, 1055.
Fauntleroy, A. M., amputations, 702.
Fauntleroy, P. C., gunshot and shell wounds, 1035.
Favus and ringworm of nails, 433.
Fay, A. S., acute myelogenous leucemia, 923.
Feces, flora of, in typhoid fever and high calory diet, 444.
Fedde, B. H., retropharyngeal abscess, 1009.
Feeble minded, commission in study, 208; law providing for sterilization of, held invalid, 19.
Feeding, infant, low fats and high proteins in, 568; infant, application of *x*-rays to, 738; people in war-time, 895.
Fees, schedule of, 1108.
Femina militans, 300.
Femur, fractured, in osteitis deformans, 960; osteosarcoma of, 780.
Ferments, defensive, experimental proof of, 771; defensive, possibility of cure of dementia precox by, 870; specific, 942.
Ferris, A. W., a brief outline of the carbon dioxide bath and its uses, 107.
Fever, gastric, acute, follicular tonsillitis with, 873; brain, 848; hypersensitiveness, and metabolism, 634; in pulmonary tuberculosis, therapy of, 1045; resorption or retention, 856; skimmed milk in, 389.
Fibrillation, auricular, diagnosis and treatment, 442; cardiac, and chloroform anesthesia, 642.
Fibrinolysis and hepatic insufficiency, 929.
Fibroid tumors, see uterus.
Fifield, H. L., acute suppurative otitis media, 249.
Filarial infection, 1071.
Fischer, C. S., the necessity for broader conceptions in gastroenterology, 834.
Fischer, L., the association of follicular tonsillitis with acute gastric fever, a clinical study of, 873.
Fishberg, M., sources of error in the diagnosis of pulmonary tuberculosis, 3.
Fisher, E. D., toxic diseases of the nervous system, with report of cases, 825.
Fistula, anal, in life insurance, 82; bronchial, 862; healed uterovesical, with abdominal extirpation of uterus, 982; vesicovaginal, with unusual phosphatic deposit, 91.
Food, and drug laws, uniformity in, 848; effects of, on metabolism in typhoid fever, 559; prices, and European war, 727.
Foot, and hand, malformations of, 780; and mouth disease, 848; club-, congenital, 589; human, mechanical considerations of, 894; muscle-bound, 812; progressive gangrene of, cured by arteriovenous anastomosis, 181; tic, 159; troubles as factor affecting human efficency, 803; weak, 902.
Formalin spray in treatment of diphtheria carriers, 158.
Forrest, E. D., the physiology of worry, 245.
Fractures, 540; about elbow joint, treatment of, 752; and burns, 538; and joint injuries, radiograms in diagnosis and treatment of, 903; birth, *x*-ray illustrations of, 739; operative treatment of, 361; traumatic malacia following, 938.
Frazer, T., mental and nervous manifestations of pellagra, 65.
Friedman, E. D., occlusion of the inferior mesenteric artery, 718.
Friedman, H. M., aspects of visual acuity, 240; problems of life, a review of the scope of our present knowledge on the subject, 788.
Fuhs, J., the flat stomach tube, its uses and limitations, 934.
Fuller, E., the surgical management of pericystitis, 573.
Fumigation, failure of, 1052.
Furunculosis, and pyorrhea alveolaris, 16; iodine and ichthyol in treatment of, 94.

G

Gall-bladder, anastomosis of, to stomach, 690; and pancreatic affections, direct examination of duodenal contents in, 527; and stomach, operations on, anoci-association in relation to, 85; infections, treatment of, 903.
Gallstones, solubility of, 514.
Gall-tract surgery, errors in, 38.
Gangrene, gas, 889, 1061, 1093; in war, 562; of foot, cured by arteriovenous anastomosis, 181; of lung following operation for ectopic gestation; resection of rib; recovery, 184; of toes, cured with Ringer's solution, 181; without organic vascular disease, 1083.

Gardiner, J., wound healing with the aid of vaccines, 19.
Gastroenterology, 834.
Gastroenterostomy, anterior, in valvulus of jejunoileum, 197; artificial stenosis of pylorus with, 985; posterior, and postoperative gastric hemorrhage, with long-loop Raux method, modified, 529.
Gastroscope and cystoscope, new, 86.
Gaucher's disease, 606.
Generative glands, implantation of, and its therapeutic possibilities, 892; variations of, causing atypical bleeding, 38.
Genetics, some problems in, 141, 439.
Genitourinary tract, general anesthesia in surgery of, 891; lesions of, arthritis associated with, 169.
Gibson, C. L., the low table position and other aids to performing suprapubic prostatectomy, 321.
Gland, pineal, 214; pituitary, see pituitary gland; suprarenal, see suprarenal gland.
Glands, endocrinic, possible insufficiency of, 804; generative, implantation of, and its therapeutic possibilities, 892; lymph, enlarged tracheobronchial, 674; tuberculous, of neck, non-operative treatment of, 437; tuberculous; topical employment of tuberculin in, 437; tuberculous, x-ray treatment of, 172.
Glaucoma, chronic, miotics in, 214; hereditary (simplex), 214; sclerocorneal trephining for, 214.
Glucose, in postoperative shock, 148; solutions, containing, 488.
Glycosuria, 981, 1015; and diabetes, and life insurance, 646; temporary, significance of, in life insurance, 174.
Goiter, and life insurance, 940; endemic and exophthalmic, 262; endemic, and water supply, 22; exophthalmic, see exophthalmic goiter; thymus extirpation in treatment of, 303.
Goldstone, K. H., the physiology of Abderhalden's reaction and its value in the determination of pregnancy, 67.
Gonococcus, carriers, 826; infections, complement fixation test in, 432.
Gonorrhea, complicated by phlebitis of penis, 285; marriage, and complement fixation test, 765.
Goodman, E. H., abdominal aneurysm as a cause of left-sided abdominal pain, 587.
Gordon, A., extrapyramidal hemiplegia, 1002; neurological and psychiatric aspects of railway accident cases, 706.
Gout, atypical, 300, 309; atypical and affections of respiratory organs, 564; high-potential currents in treatment of, 820.
Grafts, small deep skin, use of, 601.
Greeley, H., public health education, 418; the organism of smallpox, chicken-pox, and vaccinia, 204.
Green, C. R., the end of life, 295.
Grubbé, E. H., x-ray and radioactive chemicals in treatment of gynecological conditions, 98.
Gutman, J., intestinal intoxication, 363.
Gwathmey, J. T., oil-ether colonic anesthesia, 582.

H

Hagemann, J. A., a rhinological aspect of some mental disturbances, 250.
Hamilton, A. McL., London in war time, 516.
Hand and foot, malformations of, 780; extensive cicatrix deformity of, flap transplantation for, 652; athetoid movements in, 349.
Harelip, bilateral, and congenital bilateral mucous fistula in lower lip, 331.
Hartshorn, W. M., bacillus coli infections in infancy and early life, 288.
Hartshorn, W. E., a suggestion regarding the treatment of fractures about the elbow joint, 752.
Hay-fever, 170; subjects, anaphylactic skin reactions in, 891.
Headache, 355.
Health, and climate, housing and its relation to, 177; insurance construction of policy in, 32; officer and tuberculosis problem in rural communities, 630; officers, full-time, 424; public, 1072; public, and house flies, 166; public, education, 418; public, work as career, 434; wealth of, 1069.
Heart, and blood vessels, and immoderate smoking, 116; and blood vessels, disease of pains anomalously distributed in, 600; and blood vessels, therapy of disturbances of, 260; and hypochondria, 124; and kidney, disease of, 813; arrhythmia, 1072; chronic diseases of, digitalis in, 438; chronic diseases of, digitalis in, 475; chronic diseases of insurable, 1065; complications of and acute rheumatism, in life insurance, 818; congenital disease of, prognosis and diagnosis of, 41; dilated, murmurs in, 79; disease, ascites of, treatment of, 572; function, pathology of, 770; disease, pregnancy complicated by, 525; disease, prognosis of, and life insurance, 1025; diseases of, common errors in diagnosis and treatment of, 80; failure, acute, and uncompensated heart lesions, pituitary extract in, 442; fibrillation of, and relation to chloroform anesthesia, 642; functional tests of, 71; in diphtheria, 1054; in life insurance, 687; in liver diseases, 1072; insufficiency of, gastric disturbances of, 636; irregularity and life insurance, 311; "load" and "energy index," in blood-pressure studies, 179; of child, 553; pathology of syphilis of, 902; physiology of, 262; soldier's, 889; suture, case of, 123; valvular disease of, in infancy and childhood, 213.
Hecht, D. O., the public and the profession, a criticism, 867.
Hecht-Weinberg reaction, 215.
Heiser, V. G., cholera in the Philippines during 1913, 827.
Held, I. W., general diagnosis and treatment of diseases of the pancreas, 109.
Heller, J., a study of 150 cases of twilight sleep, 797.
Hemiplegia, extrapyramidal, 1002; in typhoid fever, 173; with unusual symptoms, 906.
Hemolysis, and spleen, 430; following transfusion of blood, 898.
Hemophilia treated by blood transfusion, 861.
Hemoptysis, in pulmonary tuberculosis, treatment of, 599; pneumothorax for, 307.
Hemorrhage, extensive subcapular, of liver, eclampsia showing, 184; extradural, causing aphasia, 866; gastric, 529; hysterectomy for, 641; in nose and throat operations, use of horse serum for prevention of, 441; in the newborn, transfusion in, 891; in typhoid fever, 261; intraabdominal, complicating normal pregnancy, 979; intraperitoneal, from rupture of corpus luteum, 184; occult, in ulcer of stomach and duodenum, 31; postoperative, gastric, and posterior gastroenterostomy with long-loop Roux method, modified, 529; postpartum, 1019; postpartum, and puerperal infection, 592.
Hemorrhagic disease, 645.
Hemorrhoids and varicose veins, in life insurance, 311; origin of, 644.
Hemostatic, animal blood plates as, 645; tissue as, 172; rubber sponge compression as, 772.
Heredity, 524; and life insurance, 350; and predisposition in life insurance, 958; in man, 559; in myopia, 562; problems in, 141.
Hernia, diaphragmatic, due to stab wound in chest, 861; diaphragmatic, into right thoracic cavity, 655; inguinal, under local anesthesia, operations for, 540; internal, due to aberrant middle colic artery, 85; postoperative abdominal, 302; retroperitoneal, 523.
Herpes, in pneumonia, bacteriology of, 762; zoster and malaria, 421.
Hertoghe, E., thyroid deficiency, 489.
Hexamethylenetetramine, hypodermic injections of, in treatment of typhoid fever, 362.
Hip, osteoarthritis of, 390.
Hodgkin's disease, 86; transmitted to guinea-pigs, 172.
Holmes, B., a plea for a research into the possibility of the cure of dementia precox by the use of serum containing the defensive ferment, 870.
Homicide, causal connection in, 160; defense against, by alleging negligent operation, 115.
Hospital, and ex-intern, interrelation of, 152; charitable, not liable for servants' negligence, 971; efficiency with particular reference to product rather than expenditure, 397; field, observations in, 816, 1108; liability of, for injuries to employee, 883; psychopaethie, 1059; surgical service in, 86; tuberculosis home, 438.
Hospitals, as affected by National insurance in England, 75; for whooping-cough, need of, in New York City, 227; general and mental, drugs used in, 641; liability of, for negligence, 590; open-air, in wartime, 642; prevention of communicable diseases in, 1020.
Hoxie, G. H., effects of 40 years of cholelithiasis, 749.
Hunter, G. G., the widening pellagra zone, 757.
Huntington, W. H., tonsillectomy, its indications and choice of operations, 286.
Hydrocele, topical employment of tuberculin in, 437.
Hydrosalpinx, 93.
Hydrotherapy and thermotherapy, 819.
Hygiene, child, 208; exposition at Stuttgart, 1914, 217; in coalmining, 171; of coalmining, 125.

Hyperacidity, hypersecretion, and peptic ulcer, dietetic treatment of, 732.
Hyperleucocytosis from cold, 644.
Hypernephroma, of base of tongue, 771; vertebral metastases after, 173.
Hypersecretion, hyperacidity, and peptic ulcer, dietetic treatment of, 732.
Hypersensitiveness, fever, and metabolism, 634.
Hypertension, arterial, its relation to arteriosclerosis and Bright's disease, 17.
Hyperthyroidism, 626; from surgical standpoint, 387.
Hypnosis, and vegetative centers, 1022.
Hypochondriac, cardiac, 124.
Hypopituitarism, case of, 223; post-infectious, 884.
Hysterectomy for hemorrhage, 641; supravaginal, iodine as sterilizing agent in, 399.
Hysteria and dementia precox, 298; dermatoses of, 263.
Hysteroneurasthenia or chronic appendicitis, 216.

I

Ichthyol and iodine in treatment of furuncles, 94.
Ileocolostomy for perforated stenosing ulcer of ileum, 180.
Ileum, and cecum, tuberculosis of, 180, 182; tuberculosis of, and perforated stenosing ulcer, resection, with ileocolostomy, 180.
Ileus, postoperative paralytic, 180.
Immunity, and blood platelets, 943; and parenteral digestion, 945; chronic infections and recovery with, 942; history of, 945; in measles, 523; in tuberculosis, 642.
Impotence, mechanical treatment of, 603.
Indicanemia and uremia, 732.
Indicanuria, cyclic, 86.
Indigestion, and life insurance, 392; chronic gastrointestinal, colitis gravis, and hepatic cirrhosis, 348; forerunner of diseases of cardiovascular and renal systems, 392.
Inebriety, modern treatment of, 346.
Infant, digestion of, influence of starch on, 40; feeding, boiled milk in, 40; feeding, low fats and high protein in, 568; feeding, swine fat in, 40; feeding, "whey-modified" milk in, 40; feeding, with top milk, 1043; mortality, 211; mortality and heat, 42.
Infants, and children, weights and measurements of, 570; atrophic, metabolism of, 455; suggestions for improvements, based on measurements of anthropometric methods, with, 571; malnourished, feeding of, with high proteins and carbohydrates and very low fat values, 568; newborn, and mothers, protection of, 725; stools, chemical analysis of, 569; tuberculosis in, prevention of, 596.
Infections, aerial conveyance of, 29; chronic, and recovery with immunity, 942; contact, in spread of cholera, 771; filthy railroad toilets as causes of, 727; focal, broader application in the etiology of general disease, 35; focal, of nose, throat, mouth and ear, 892; focus of, in osteitis, 1027; in tuberculous families, 346; latent, and salvarsan treatment, 563; mouth, parenchymatous nephritis from, 893; postoperative, cancer of uterus apparently cured by, 693; puerperal, and postpartem hemorrhage, 592; pyogenic, of upper urinary tract, 520; respiratory, autoimmunization in, 408; various, newer bacteriology of, 35.
Infectious disease, and thromboangiitis obliterans, 863; question of contact with, 896; treated by injections of mercury, 49.
Inflation, colonic in chronic appendicitis, 528.
Injuries, evidence as to, 845.
Insanity, and divorce, 980; among Jews, 576, 609; causes of, 74, 215; faradic stimulation in, 1099; management of, 725; manic-depressive, 521; prevention of, 527; problems in, 1100.
Insomnia, "don'ts" in treatment of, 1076; treatment of, 303.
Insufflation, intratracheal, 509.
Insurance, industrial, 82; life, see life insurance; national and tuberculosis, 210; substandard, 218.
Intervertebral foramen, 852.
Intestinal stasis, 472, 473, 965, 1019; chronic, 145, 477, 531; chronic, operative findings in, 693; medical treatment of, 440; nonsurgical treatment of, 820.
Intestine, and stomach, studies of, 558; and stomach, surgery of in relation to life insurance, 604; and stomach, treatment of affections of by electrical and mechanical modalities, 820; antisepsis of, by *Bacillus bulgaricus*, 233; artificial fistula of, after abdominal operation, 933; complications of, in the puerperium, 93; diseases of, cyclical albuminuria in, 86; in chronic constipation, *x*-ray examination of, 730; inclusion of loop of in omental torsion, 643; intoxication from, 363; large, resection of, for malignancy, 180; musculature of, effects of caffeine and nicotine on, 389; obstruction of, 530, 641; obstruction of, acute, 681; obstruction of, clinical and experimental results in, 85; parasites of, in adults, 1072; prolapse of, in field, treatment of, 857; putrefaction in, with convulsion, 1018; small and duodenum, cancer of, 809, 814; stasis in, see intestinal stasis; toxemia of, and diabetes, 1085; wall of, diffusion of bacteria into, 530.
Iodine, and complete sterilization of skin, 400; and ichthyol in treatment of furuncles, 94; influence of, on procreation, 173; as sterilization in supravaginal hysterectomy, 399.
Iodoform, intravenous injections of, in treatment of leprosy, 125.
Iritis, toxemic, 684.

Mallory, W. J., the physiology of gastric motility, 447.
Maloney rest exercise method, 821.
Malpractice, 511; evidence of, 251; insufficient evidence of, 160, 1010
Mango, as a lymphagogue, 27.
Marching, morbidity from, 1024.
Masochism, infantile roots of, 822.
Mastoid disease, acute, laboratory aids in, 1; disease, acute, laboratory aids in, 43; operation, modified and conservative radical, for tolerance of prothesis in cases of diminished hearing after middle-ear suppuration, 64; region of skiography of, 519; tuberculosis of, 732.
Mastoidectomy, bilateral, diabetes mellitus following maxillary sinuses, 510.
Mays, T. J., state prevention and pulmonary consumption, 336

Measles, immunity in, 523; vagaries of, 676.
Medicine, illegal advertisements in, 883; agreement not to practise, 1052; clinical, in time of Auenbrugger and Laënnec, 415; enforced dogmatism in, 855; expert in, see expert; faculty of, in original university of Louvain, 829; from chemical standpoint, 313; general, and industry to, 852; internal, and syphilis, 556; license to practise law, see license, medical; military and naval, literature of, 637; or surgery, license to practice special branch of, 845; popular education in, 123; practice of, 820; practising, illegally, proof of residence, 883; practising, without a license, 115; practice of, without authority, 1052; preventive, father of, 908; profession of and public, 867; profit and loss account of, 1069; progress of, and war, 340; proprietary in England, 518; relation of, to municipal government, 1073; service of, to civilization, 78; simpler methods of physical examination in, 1070; socialization of, 199.
Medicines, patent, Committee of House of Commons, 639, 679.
Meninges and spinal cord, treatment of inflammatory conditions of, 820.
Meningitis, cerebrospinal, in New York, 763; meningococcus refractory or so-called "fast" cases of, 39; parameningococcus, 552; pneumococcus, 853; serum, absence of preservatives in, 807; serum, preservatives for, 675; streptococcic, magnesium sulphate in, 1018; tuberculous, arrest of, 325; vaccination against, 1100.
Menorrhagia and metrorrhagia, etiology of, 213.
Meckel's diverticulum, 571.
Mercury, bichloride poisoning, recovery from, 844; bichloride poisoning, treatment of, 133; detection of, in the excreta, 132; muscular injections of in treatment of infectious diseases, 49.
Metabolism, and sugar, 643; fever, and hypersensitiveness, 634; gaseous, of infants, 485; in typhoid fever, effects of food on, 558; of atrophic infants, 455; of carbohydrates with special reference to its effects on the absorption of fat and nitrogen and on the retention of salts, 41; protein, in experimental pancreas diabetes, 763; purin, and internal secretions, 885.
Metrorrhagia, 155; and menorrhagia, etiology of, 213.
Microscopy, early period of, 22.
Midwives, training of, 26.
Milium, congenital, 310.
Milk, boiled, in infant feeding, 40; calcium, for sick nurslings, 564; certified, in England, 167; cow's, raw and heated, 58; pasteurization of, and infantile scorbutus, 484; skimmed, in fever, 389; lap, infant feeding with, 1043; "whey-modified" in infant feeding, 40.
Miller, H. R., a preliminary report on a method of treatment for diphtheria carriers, 158.
Mind, and nerves, disturbances of, following castration in women, 769; anomalies of, arteriosclerotic and constitutional, and life insurance, 564; defects of, and divorce, accidents, crime, etc., 14; disorders of, ergotherapy in, 430; disturbances of, some rhinological aspects of, 250; in pellagra, 65; point scale for measuring capacity of, 1059.
Mirror, head, and face protector, 971.
Mitral valve, stenosis of, 350; stenosis of, and life insurance, 478.
Molluscum contagiosum, 780.
Montgomery, D. W., syphilophobia, 464.
Morphinism, prognosis of, 30.
Mortality, after prostatectomy, 1018; cancer as cause of, in Prussia, 392; causes of, and life insurance, 858; infant, 211; infant and child, 426; infant, and heat, 42; law, in Manila, 211; of cholera in Manila, 890; of insured syphilities, 311; unexpected, and life insurance, 940.
Morton, W. J., imbedded radium tubes in the treatment of cancer, with report of a case of sarcoma remaining cured nine years after radiation, 913.
Mouth, infection and systemic disease, 1060; focal infection of, 893; infection, vaccine in relation to, 943; infection, parenchymatous nephritis from, 893.
Mumps and pancreatitis, 434.
Munroe, J. P., salvarsan in the treatment of syphilis, with special reference to the use of salvarsanized serum in cases of syphilis of the central nervous system, 543.
Murmurs, cranial, 675; in dilated hearts, 79.
Muscle, and ligament affections, 181; and ligament affections, massage and movements for, 183; levator ani, suture of, in perineorrhaphy operations, 344; tissues, application of, to physiological standardization, 442.
Myasthenia gravis, 319.
Myatonia congenita, 307.
Myelitis, acute infectious complicating pregnancy, 135; disseminated, of doubtful origin, 132.
Myocardium, chronic disease of, acidosis terminating, 30.
Myomectomy, with extensive resection of uterus in fibroid tumors, 691.
Myositis ossificans, 813.
Myotonia atrophica, 131.
Myxedema allied to infective exhaustive group, 917.

N

Nails, favus and ringworm of, 433.
Nammack, C. E., progressive lenticular degeneration, 997.
Narcolepsy, 762.
Narcosis, in dentistry, 385; scopolamine-morphine, in labor, use of, 694; see also twilight sleep.
Narcotics, administration of, causing death, 115.
Nascher, I. L., the neglect of the aged, 457.
Needles, emanation, radium therapy by means of, 172; migrating, 885.
Negligence, and expert evidence, 674; liability of hospitals for, 590; not perceived in failure to effect a cure, 115; of hospital nurses, liability of operating surgeon for, 297; servants, charitable hospital not liable for, 971.
Negro, medical aspects of, 1068; skin diseases in, 274.
Neosalvarsan, behavior of, 680; intravenous injection of, simple method for, 320.
Nephrectomy, for tuberculosis, 223.
Nephritis, acute, *a frigore*, 1; and arteriosclerosis, blood pressure, and pulse pressure in, 805; and arteriosclerosis, relation of arterial hypertension to, 17; and nephrosis, 762; ascites of, treatment of, 572; creatin and creatinine elimination in, 1031; diuretics in, 572; experimental, 122, 163; modern treatment of, 728; parenchymatous, from mouth infection, 893; present-day conception of treatment of, 902; sodium chloride in treatment of, 42.
Nephroptosis, 730.
Nephrosis and nephritis, 762.
Nerve, block and tuberculosis, 853; blocking, 395; deafness associated with anemia, 766; facial, bilateral paralysis of, 682; sciatic, stretching of, 677; transplantation in laryngeal paralysis, 872; ulnar, injury of, 473.
Nerves, and mind, disturbances of, following castration in women, 769; sixth and seventh cranial, congenital defect, 423.
Nervous system, and cutaneous pigmentation, 1054; autonomic, 610; central and modern syphilis therapy from biological point of view, 900; central, defect symptoms after affections of, 349; central, fixation of poisons by, 380; diseases of, in school children, 571; in pellagra, 65; in secondary syphilis, involvement of, spinal fluid with reference to, 270; syphilis of, salvarsanized serum in, 29, 946; toxic diseases, 777, 825.
Neuhof, S., auricular flutter occurring during rheumatic endocarditis, 63.
Neuralgia, alcohol injections in, 936; brachial, new symptom of, 684.
Neurasthenia, objective signs of, 71; splanchnic, 820; vicious circles of, 126.
Neuritis, multiple, with astasia-abasia, 907.
Neurology, examinations in, 936.
Neurosis, and purpose, 840; drink, periodicity of, 628.
Neurovascular training, 198.
Newton, R. C., sketch of the origin of auscultation and percussion, and of the state of clinical medicine in the time of Auenbrugger and Laënnec, 415.
North, J., back to the soil, the relation of pulmonary tuberculosis to soil formation, 969.
Nose, and asthma, experimental studies on, 122; and throat operations, horse serum in prevention of hemorrhage in, 441; congenital atresia of posterior orifice of, 525; deformity of, use of section of scapula in correcting, 431; diseases of, and mental disturbances, 250; plastic, surgery of, 302; posterior orifice of, congenital obstruction of, 518; submucosa of, absorption of suprarenal extract from, 214; throat, mouth, and ear, focal infection of, 892.
Nutrition, carbohydrate in, 642; parenteral, and its surgical application, 148; principle of, 1021; work on, respiration calorimeter in, 444.

Obstetrics, operations in, motion pictures of, 807; twilight sleep in, see twilight sleep.

Occupation and disease, 1100; diseases of, and public health, 852; diseases of, due to calcium nitride; diseases of teeth in, 72; therapy, in organic diseases, 346.

Omentum, torsion of, 643.

Operation, after-results of, and life insurance, 392; at home, 693; negligence in, no defense against homicide, 115; plastic, for correction of cecocolon stasis, 693; shockless (anoci-association), 561; shockless, evolution of, 361; without consent, 160.

Ophthalmia, phlyctenular, 390.

Ophthalmology, Bier's substitution therapy in, 572; war, 857.

Oppenheimer, A., gangrene without organic vascular disease, 1083.

Orbit, cellulitis of, treatment of, 759.

Ossiculectomy, 584.

Osteitis, a focus of infection, 1027; deformans, case of, 93; deformans, fractured femur in, 950.

Otitis media, acute suppurative, 249.

Overweight as surgical risk in life insurance, 564; habit of, and life insurance, 565.

Ovaries, carcinoma of, failure of *x*-rays in, 596; cysts of, observation on torsion of, 690; resection of, 693; transplantation of 345.

Oxygen compartments for travelers, 908.

P

Pabst, C. F., why fumigation fails, 1052.

Packard, E. N., therapy of fever in pulmonary tuberculosis, 1079.

Pain, abdominal, left sided, abdominal aneurysm as cause of, 587; acute abdominal, caused by accessory spleen, 937; anomalously distributed in cardiovascular disease, 600; as symptom of disease of spinal cord, 907; back, and its diagnosis, 77; gas, after appendicectomy, relief of, 892; left-sided abdominal, abdominal aneurysm as cause of, 528; sciatic, 1019.

Palacios, G. D., why yellow fever is endemic in the tropical and Atlantic region, 150.

Palate, and tongue, soreness of, early symptoms of pernicious anemia, 349; and upper part of larynx, syphilitic thickening of, 422; cleft, factors of safety in surgery of, 519; cleft, surgery of, 519; deficiency of, 780.

Pancreas, achylia, and acute pancreatitis, 81; and gall-bladder, affections of, direct examination of duodenal contents in, 527; diabetes, experimental, protein metabolism in, 763; diseases of, general diagnosis and treatment of, 109; diseases of, urinary diastase test and Loewy's reaction in, 29; secretion of, effect of sodium bicarbonate on, 216.

Pancreatitis, acute, and pancreas achylia, 81; and mumps, 434.

Paraffin in constination, 557.

Paragensia and its treatment, 438.

Paralysis, agitans, and parathyroids, 973; facial, 682; hysterical brachial, following electrical shock, 740; infantile, see poliomyelitis; laryngeal, nerve transplantation in, 872; obstetrical, 169, 275; poliomyelitis, flail joints in, intraarticular silk reinforcement of, 274; postdiphtheritic, 681; spastic, 780; spastic, new operative treatment for, 89; spondylitic, and laminectomy, 172.

Parametritis, and backache, 548.

Paraphrenia, 477.

Parathyroids and paralysis agitans, 973.

Paratyphoid, and typhoid bacilli, isolation of, 299; fever, blood picture in, and after vaccination with *Bacillus typhosus*, 728; fever epidemic at Boston State Hospital, 728; fever, epidemiological features in, 727; fever, pathology of, 857.

Paresis, 475; cerebrospinal fluid of, infectivity of, 75; diagnosis and treatment of, 680; tabes, and cerebrospinal syphilis, salvarsanized serum in treatment of, 901; treatment of, 1070.

Paris, in war time, 594, 810, 1017.

Park, F. E., two cases of treatment by radium emanation, 380.

Parker, G. M., neurosis and purpose, 840.

Paronychia, 268.

Parotid gland, extirpation, 652.

Parsons, Ralph L., presentation of memorial of, 611.

Pasteur, Louis, 1108.

Parturition, and pregnancy, in contracted pelvis, 353; complete inversion of uterus following, 135; hemorrhage after, 1019; obstructed, danger of oxytocics in, 27; painless, 843; scopolamine-morphine narcosis in, 694; labor, scopolamine-morphine semi-narcosis in, 694.

Pedal tic, 159.

Pediatrics, and social-medical work, 606; atropine methyl bromide in, 992.

Pellagra, 378; mental and nervous manifestations of, 65; notifiable disease, 593; study of, 22; treatment of, 642; treatment of, by high-frequency current, 820; zone, widening, 757.

Pelvis, abscess of, following employment of Fowler position in appendicitis, 1029; contracted, management of pregnancy and labor in, 353; floors of, lacerations of, technique for separately uniting, 399; varieosities of, 31; viscera of, abdominal distention following operations upon, 692.

Pemphigus, neonatorum, 682; vegetans cured by salvarsan, 553.

Pendexter, S. E., the treatment of orbital cellulitis, 759.

Penis, phlebitis of, 285.

Percussion, and auscultation, origin and development of, 179; and auscultation, origin of, 415; of lungs, 179.

Pericarditis, treatment of, 260.

Pericysitis, surgical management of, 573.

Perineorrhaphy, fundamental intrapelvic, 38; primary, by buried and subsurface catgut suture, 259; suture of levator ani muscle in, 344.

Peritonitis, general, and postoperative paralytic ileus, complicating enterostomy and appendicitis, 189; pneumococcus, 1100; treatment of, and kinetic system, 691.

Pertussis, clinical and sociological aspects of, 225; diagnosis of, by complement deviation test, 480; etiology of, 224; need of hospitals for, in New York City, 227; treatment of, 3, 226; vaccine treatment of, 39, 806.

Peters, A. W., the sterilization of mental defectives considered from the physiological standpoint, 370.

Pharmacy and chemistry, council on, 1072.

Phenol-serum treatment of pyogenic processes, 656.

Phenolphthalein, acute poisoning by, 232.

Phenolsulphonephthalein, in testing renal function, 732.

Philbrick, I. C., socialization of medical training and practice, 199.

Physician, acquisition of capital by, 278; and his business expenses, 278; as expert, see expert; avocations of, 698; Belgian, appeal for, 1053; compensation of, from county, 845; disqualified as witness, 1010; employment of, by claim agent, 511; employment of, by officers of corporation, 720; future of the, 121; liability of, for substitute, 380; sale of practice of, 720; services, liability of local authorities for, 590; services of, rendered to decedent, proof of, 590; services of, father's liability for, 251; services of, rendered in emergency, 465; old-time, 1072; unlicensed, how to proceed against, 762.

Pilocarpine in high blood pressure, 892.

Pineal gland, deficiency symptoms of, 722.
Pituitary, and thymus extracts, in treatment of exophthalmic goiter, 75; extract, 348; extract, in acute heart failure and uncompensated heart lesions, 442; gland and sella turcica, 171; gland, diminished function of, postinfectious, 884; gland, disorders of, 853; gland, tumors of, 171.
Plague, curve, 211; Havana free from, 209; in Europe, incidence of, 981; in Hong Kong, 727; in New Orleans, 119, 163, 342; in Philippines, 344; in the South, 22; prevention of, in Philippine Islands, 76.
Pleura, mediastinal effusion of, 815; tuberculous exudates of, reaction of Moreilli in, 811.
Pleurisy, pulsating, 339.
Pneumolysis, intrapleural, in pulmonary tuberculosis, 654.
Pneumonia, and *x*-rays, 739; diphtheria antitoxin in treatment of, 320; experimental, 310; herpes in, bacteriology of, 762; lobar, treated by special method, 87; patient, management of, 993, 1028; serum treatment of, 188, 224.
Pneumothorax, artificial, 259; artificial, as associate treatment in pulmonary tuberculosis, 474; artificial, in pulmonary tuberculosis, 206, 355; artificial, pleural effusions of, 1068; artificial, present status of, 599; for hemoptysis, 307; spontaneous, 179.
Poisoning, anaphylactic and apotoxic, 939; egg, and asthma, in children, 891; fatal, from quinine-veronal combination, 731; mercury bichloride, recovery from, 844; mercury bichloride, treatment of, 133; mushroom, 212; phenolphthalein, 232.
Poliomyelitis, acute, celluloid splints in, 309; paralysis, flail joints in, intraarticular silk reinforcement of, 274; surgical treatment of, 476; tenoplasty in, 76.
Polyclinic medical school, New York, lectures delivered at, 538.
Polycythemia rubra, 844.
Polyglobulia and disease of liver, 20.
Pott's disease, in cervical region, bony splinting in, 361; laminectomy in, 172.
Pregnancy, Abderhalden reaction in, 67, 942; acidosis and nitrogen partition in, 354; acute infectious myelitis complicating, 135; and cancer, serum diagnosis of, 309; and cancer, serum diagnosis of, 560; and incipient and inactive tuberculosis, 693; and labor, in contracted pelvis, 353; and life insurance rejection, 818; and myoma, 563; and puerperium, *Bacillus coli* infections during, 222; and sterilization in tuberculosis, 771; complicated by severe morbus cordis, 525; cuti-reaction in, 564; ectopic, and general practitioner, 693; ectopic, gangrene of lung following operation for, resection of rib; recovery, 184; normal, intraabdominal hemorrhage complicating, 979; ovarian, 933; suppurative appendicitis in, 184; toxemia of, ocular manifestations of, 124; toxemia of, treatment by duodenal enema, 102; vomiting of, phenol-serum treatment of, 656.
Progeria, 212.
Prognosis, 261.
Prostrate, cancer of, 429; cancer of, modification of perineal operation for, 429; cancer of, radiation therapy of, 429; disease of, median bar obstruction in, 768; hypertrophy and cancer of, 429; hypertrophy of, endourethral treatment of, 161.
Prostatectomy, factors which determine advisability of, 898; mortality after, 1018; mortality, reduction of, 1019; suprapubic, low table position and other aids to performing, 321.
Prostatitis, chronic, and its treatment by general practitioner, 962.
Proteins, high and low fats in infant feeding, 568; metabolism in experimental pancreas diabetes, 763.
Pruritus, powder for, 232; triple-acid ointment for, 320.
Pseudoleucemia, treatment of, 645.
Psychiatry and war, 857.
Psychoneuroses, emotional factor in, 903; genetic factors in, 1019.
Psychopathic hospital, Boston, recoveries at, from standpoint of nursing, 641; of pernicious anemia, 559.
Puerperium, and pregnancy, *Bacillus coli* infections during, 222; infection of, and postpartum hemorrhage, 592; infection of, vaccine treatment of, 27; intestinal complications of the, 93; malaria during, 27; pyemia of, 779; thrombophlebitis of, treatment of, 693.
Pulmonary tuberculosis, 475; advanced, erythrocytes in, 70; advanced, treatment of, 741; and State prevention, 336; artificial pneumothorax as associate treatment in, 474; artificial pneumothorax in, 206, 355, 599; care of cases of, advantages of State control over county institutions for, 179; complicating appendicitis 601; crusade against, 476; diagnosis of form of, 685; diagnosis of, sources of error in, 3; early diagnosis of, 348, 778; errors in diagnosis of, 28; family infection in, 346; therapy of fever in, 1045; incipient, and mild thyroid toxemia, 179; intrapleural pneumolysis in, 654; new operative procedure in, 552; rest or exercise in treatment of, 178; syphilis of lungs simulating, 330; thermopenetration in treatment of, 437; treatment of hemoptysis in, 599; *x*-ray diagnosis of, 599; *x*-ray in, 820.
Pulse, irregular, 1022; pressure and blood pressure in arteriosclerosis and nephritis, 805; rate, and suprarenals, 260.
Pumpkin, as diuretic, 513.
Pupil, hemiopic reaction of, 523; phenomenon, Loewi's, 637.
Purin metabolism and internal secretions, 885.
Purpura, annularis telangiectodes, 270; hemorrhagica, treated by blood transfusion, 861; in animals, 29.
Putnam, Dr., memorial to, 483.
Pyelography, present status of, 37.
Pyemia, puerperal, 779.
Pylephlebitis, pathology and diagnosis of, 591.
Pylorus, and duodenum, obstruction of, 389; and duodenum, ulcer of, closure of pylorus for, 854; artificial stenosis of, with gastroenterostomy, 985; closure of, for pyloric and duodenal ulcer, 854; exclusion of, in treatment of ulcer, 37; obstruction of, in infants, 855; spasm of, 737; stenosis of, 528, 692, 992.
Pyorrhea alveolaris and furunculosis, 16.

Q

Question, hypothetical, 720, 927; hypothetical as to cause of pain, 1052.
Quinine-veronal combination, death from, 731.

R

Rabies, in New York, 886; virus, artificial cultivation of, 935.
Radium, and roentgen rays, in primary carcinoma of vagina, 195; and surgery in cancer, 615; applied to neoplasms of bladder, 213; beta rays, 909; emanation, treatment by, 380; in cancer and allied conditions, 979; in carcinoma of breasts and axillae, 180; in surgery, 279; in treatment of cancer, 70; in treatment of cancer of uterus, 898; in treatment of ear diseases, 376; therapeutics, 55, 1069; therapy by means of emanation needles, 172; treatment of cancer, 651; treatment of internal tumors, 303; treatment of uterine hemorrhage, 38; tubes, imbedded, in treatment of cancer, 913; in carcinoma, 645.
Radley, J. H., spinal subluxations; their nature and cause, 203.
Rankin, E. G., the readings of the syhygmomanometer from a clinical standpoint, 1045.
Rectum, aerophagia of, 722; benign or doubtful tumors of, 77; bladder, and uterus, operation for displacement of, 692; cancer of, 934; carcinoma of, 135.
Red Cross, International, 382; ship, American, 468; Society of England, 470, 933.
Reflexes, abdominal, 400; elicitation of, 854.
Relapsing fever, spirochete of, 780.
Reproduction and race betterment, 117.
Respiration calorimeter in nutritional work, 444; in clinic, 444.
Respiratory organs, and a typical gout, 564; autoimmunization in infections of, 408; tract, in children, staphylococcus infection of, 252; tract, upper phlegmons of, 1018.
Rest, exercise method, Maloney, 821; or exercise, in treatment of pulmonary tuberculosis, 178.
Rhinolith in child, 673.
Rheumatism, acute, and cardiac complications, in life insurance, 818; acute salicylates in, 642; and life insurance risks, 478; etiology, 382.
Rib, cervical, operation for, 655.
Richter, G., mistakes made in taking and interpreting blood pressure readings, 837.
Rickets, deformities, 780; pathology and prophylaxis of, 607; thoracic complications of, 42.
Ricketts, B. M., intratracheal insufflation, 505.
Ringworm, and favus of nails, 433; of scalp, 853; of scalp, treatment of, 853.

Robinson, B., conservatism in the treatment of disease, 199; practical points in tonsillar infection, 799.
Robinson, W. J., chronic prostatitis and its treatment by the general practitioner, 962; gonorrhea, marriage, and the complement fixation best, 765.
Rockwell, A. D., the diathermic treatment, 1006.
Roper, J. C., serum treatment of pneumonia, 188.
Rosenstirn, J., notification of venereal disease, 343.
Rotch, Dr. Thomas Morgan, memorial to, 483.

S

Sacroiliac conditions, 820.
Salvarsan, action of, on fetus, 684; as an abortive of syphilis, 31; in non-syphilitic diseases, 308; in syphilitic nervous disease, 29; in treatment of pernicious anemia, 37; in treatment of scarlatina, 817; in treatment of syphilis, 405, 543, 772; pemphigus vegetans cured by, 553; serum, treatment of tabes, 901; treatment and latent microbism, 563.
Salpingitis treated by abdominal approach, 212.
Salt solution, abuse of, 260.
Sanatoria, private, for tuberculosis, 179; State, efficiency in, 521.
Sarcoma, Coley's mixed toxins in, 388; fowl, generated by filtrable virus, 216; giant cell, successfully treated by surgery and *x*-rays, 720; multiple idiopathic pigment, treated by *x*-rays, 740; myeloid, 1061; osteo-, of femur, 780; transplantable, influence of diet on, 649.
Sarcomatosis of kidneys, 542.
Satterthwaite, T. E., some problems in genetics, 141.
Savini, C., microscopical traumatic lesions of the mucosa found in some recent cases of appendicitis, 915.
Sawdust as surgical dressing, 772, 815.
Scapula, Spreugel's deformity of, 780; use of section of, in correcting nasal deformity, 431.
Scarlatina, salvarsan in, 817.
Schapps, J. C., the country physician and congenital clubfoot, 589.
Schizothymia and cyclothymia, 937.
School, children, nervous diseases of, 571; children, physical examination of, by private physicians, 886; medical, making of a Scottish, 313; room, disease and dust, prevention of, 331; dental, and the teaching of oral surgery, 801; medical, needless alarm over control of, by American Medical Association, 22.
Schwarz, E., metrorrhagia, 155.
Sciatic nerve pains, 1019.
Sciatica, stretching of nerve in, 677.
Sclera, blue, with fragility of bones, 224; tuberculosis of, 455.
Sclerocorneal trephining for glaucoma, 214.
Scopolamine-morphine, narcosis in labor, 694; semi-narcosis in labor, 694.
Scurvy, and beriberi, affinities of, 729; infantile, and pasteurization of milk, 484; infantile, blood, blood-vessels and diet, 990; origin and course of, in German southwestern Africa, 81.
Seasickness, treatment of, 362.
Secretions, internal, and dental caries, 127; internal and purin metabolism, 885; internal, disturbances of, in chlorosis, 127; internal, in gynecological and obstetrical patients, 399; internal, paths of, 244.
Sella turcica, and pituitary gland, 171; lesions around, 907.
Seminarcosis, scopolamine-morphine, in labor, 694.
Senility and Lane's complex, 347.
Sepsis, following curetting after spontaneous abortion, 92; in recognition and nonrecognition of syphilis, 560; oral, wholesale extraction of teeth for, 428; treatment of, in army, 1064.
Serum, and phenol treatment of vomiting of pregnancy, 656; antimeningitis, absence of preservatives in, 807; antimeningococcus, choice of preservative for, 675; antistreptococcus, 730; containing defensive ferment, possibility of cure of dementia precox by use of, 870; diagnosis of pregnancy and cancer, see Abderhalden reaction, 309; diagnosis, see Abderhalden reaction; horse, in prevention of hemorrhage in nose and throat operations, 441; mercurialized, in treatment of cerebrospinal syphilis, 907; salvarsanized in syphilis of central nervous system, 946; salvarsanized, in treatment of locomotor ataxia, paresis, and cerebrospinal syphilis, 131, 901; treatment of pneumonia, 188, 224.
Sex and recent fashions, 874.
Sexton, L., observation on malarial fever, 334.
Sheddan, L. L., danger of oxytocics in obstructed labor, 27.
Shock, anaphylactic, autoserotherapy in, 232; from fright, evidence of, 845; postoperative, use of glucose in, 148; traumatic, 972.
Sicard, M. H., trichinosis, with a report of cases, 282.
Sigmoid, diverticulitis, 224; diverticulitis simulating malignancy, 190; flexure of colon, adhesions of, 92.
Sigmoidoscopy, 475.
Simon's symptom-complex, 208.
Simpson, C. A., annular serpiginous, bullous eruption complicating vaccination, 920.
Skin, colloid degeneration of, 273; complete sterilization of, by iodine, 400; diphtheria of, 308; disease in negro, 274; diseases of children, prescriptions for, 656; grafts, small deep, 601; pigmentation and nervous system, 1054.
Sleep, disorders, 686; twilight, see twilight sleep.
Slides, and cover glasses, simple method for cleaning, 257.
Smallpox, chickenpox and vaccinia, organism of, 204; diagnosis of, 817; scars, treatment of, 938.
Smears, 639.
Smoking and duration of life, 264; immoderate, and the cardiavascular system, 116.
Sodium, bicarbonate, effect of, on pancreatic secretion, 216; bromide in gastric therapeutics, 94; chloride in treatment of nephritis, 42.
Soil, back to the, 969.
Soldiers, and athletes, accessory article of diet for, 816; footgear of, 855; heart, 889.
Solis-Cohen, M., the subjective and objective symptoms of favorable and unfavorable reactions to tuberculin, 756.

Sterilization, in tuberculosis simultaneous with interruption of pregnancy, 771; law declared invalid in Iowa, 23; law held invalid in New Jersey, 19; of mental defectives considered from physiological standpoint, 370; of organic extracts, ultraviolet rays in, 488.
Stewart, D. H., smears, 639.
Stillman, E. G., the immediate results of salvarsan treatment of syphilis, as judged by the Wassermann reaction, using a cholesterin fortified antigen, 405.
Stomach, absence of trypsin in, in presence of icterus, 123; acidity in, tropeolin as indicator for, 768; acute fever attributed to, follicular tonsilitis with, 873; anastomosis of gall bladder to, 690; and duodenum, atony of, 817; and duodenum, ulcer of, ruptured, 692; and duodenum, ulcer of, 898; and intestine, treatment of affections of, by electrical and mechanical modalities in, 820; and duodenum, ulcers of, diagnosis and treatment of, 95; and duodenum, ulcer of, end results of cases of, 34; and duodenum, ulcer of, occult hemorrhage in, 31; and gallbladder, operations on, anociassociation in relation to, 85; and intestine, diseases of, see gastrointestinal diseases; and intestine, indigestion of, colitis gravis, and hepatic cirrhosis, 348; and intestine, studies of, 558; and intestine, study of, see gastroenterology; and intestine, surgery of, in relation to life insurance, 604; anesthetization of, in treatment of diarrhea, 349; cancer of body of, diagnostic peculiarities of, 643; cancer of, in the young, 34; cancer of, symptomatology of, 528; cancer of, transition of, into ulcer and of gastric ulcer into cancer, 528; chronic ulcer of, production of, 898; diseases of cyclical albuminuria in, 86; disturbances of cardiac insufficiency, 636; gunshot and bayonet wounds of, 767; gunshot wounds of, 1101; hemorrhage of, 529; infant, types of, 739; lesser, curvature of, ulcer of, 191; motility of, Boas chlorophyl test for, 529; motility of, physiology of, 447; postoperative hemorrhage of, 529; removal of, 384; residuum of, 124; therapeutics of, sodium bromide in, 94; tube, flat, its uses and limitations, 934; ulcer and carcinoma of, radiological differential diagnosis of, 528; ulcer of, and its surgical treatment, 557; ulcer of, belladonna in, 572; ulcer of, duodenal ulcer, and chronic appendicitis, difference in morphology of blood in, 133; ulcer of, experimental chronic, 308; ulcer of, operative treatment of, 304; ulcer of, perforated, *x*-ray findings in, 1074.
Stone, W. B., acute myelogenous leucemia, 923.
Stone, W. J., comparative Wassermann, cobra, and globulin tests in syphilis, with a report of one hundred and five reactions, 545.
Stools, chemical analysis, 569.
Stow, B., Metchnikoff's basic principal, intestinal antisepsis through biological aids, attested by the *Bacillus bulgaricus*, 233.
Strauch, A., acute leucemia, 713.
Streptococcus, and cholecystitis, 981; arthritis, surgical treatment of, 309; causing necrotic bronchopneumonia, 443.
Streptolysin, 721.
Strophanthus, clinical notes on, 263.
Strychnine, synthetic derivatives, 94.
Sugar, content of blood in cancer, 650; Fehling's solution in testing for, comparative uselessness of, 174; in animal body, 643; increase in amount of, in blood of old diabetics, 217; therapeutic use of, 339.
Sulphonal, fatal hematoporphyrinuria from, 434.
Suprarenal, extract, nasal absorption of, 214; gland, 126; and virilism, 426; and pulse-rate, 260; glands, recent investigations on, 761.
Surgeon, liability of, for negligence of hospital nurses, 297; of the future, 315; standardization of, 86; the useful, 420.
Surgery, and radiotherapy of cancer, relation between, 615; biliary, 620; bloodvessel, 856; general, relation of gynecology and urology to, 872; gynecologist in domain of, with special reference to malposed kidney, 906; gynecology and urology, 906; home of, in Washington, 23; hospitals, 86; in war, 1012; morbidity in, 693; notable clinic of, 551; of gastrointestinal disease in its relation to life insurance, 604; of spastic paralysis, 89; or medicine, license to practice special branch of, 845; parenteral nutrition in, 148; military, 895; military, first weeks of activity in, 982; of genitourinary tract, general anesthesia in, 891; oral, teaching of, and dental school, 801; pinewood sawdust as dressing in, 815; status of specialist in field of, 905; radium in, 279; risks of, overweights, as in life insurance, 564; standardization of, 38, 86; topical employment of tuberculin in, 437; urology and gynecology, 905; use of glucose in, 148.
Swanberg, H., the intervertebral foramen, 852.
Syphilis, and dermatology, cases in, of unusual interest, 779; and internal medicine, 556; and life insurance, 896; and lupus, 731; cerebral, in secondary stage, 422; cerebrospinal, mercurialized serum in treatment of, 907; cured, cerebrospinal examinations in, 390; diagnosis of, Abderhalden's technique as applied to, 270; direct subdural injections in, 37; error in salvarsan treatment of, 772; inherited, late manifestations of, with special reference to arterial disease, 36; infantile, 780; inherited, late cerebrospinal manifestations of, 775; late hereditary, diagnosis and treatment of, 608; modern treatment of, 711; new treatment of, dangers attending, 392; of central nervous system, salvarsanized serum in, 946; of larynx and palate, 422; of heart, pathology of, 902; of lung, 556; of lungs, simulating pulmonary tuberculosis, 330; of nervous system, salvarsan and, 29; of nervous system, treatment of, 1070; paternal inheritance of, 81; pathology of, 347; phobia of, 464; primary lesion of, in rabbits, 1023; salvarsan as abortive of, 31; salvarsan in treatment of, 543; salvarsan treatment of, immediate results of, as judged by Wassermann reaction, using cholesterin fortified antigen, 405; secondary, involvement of nervous system in, spinal fluid with reference to, 270; sepsis in recognition and nonrecognition of, 560; sero-enzyme test for, 390; spirochete of, 780; treatment of, 453, 900, 1070; two abortive cures of, in same subject, 938; various types of, 37; Wassermann, cobra, and globulin tests in, 944; yellow atrophy of liver after, 551.
Syphilitics, insured, mortality of, 311.
Syringomyelia, 672.

T

Tabes, and exophthalmic goiter, interrelation of, 27; determinants of, 28; paresis, and cerebrospinal syphilis, salvarsanized serum in treatment of, 901; suggestive of Friedreich's ataxia, 907; superinfection in, 1101; Swift-Ellis treatment of, 131; treatment of, 1070; with hippus, 907; with lost tendon-reflexes and Argyll-Robertson pupils, 907.
Teeth, and alopecia, 592; in occupation diseases, 72; wholesale extraction of, for oral sepsis, 428.
Temperature, body, in childhood, 126; prolonged subnormal, in tuberculosis, 176; normal and pathological, borderline between, 644.
Tendon, long, of biceps brachii, intracapular rupture of, 846; plastic operation on, see teno-

plasty; transplantation of in poliomyelitis, 76.
Tenoplasty, for ischemic contracture, 861; in poliomyelitis, 76.
Testicle, transplantation of, 170; tumors, 1060.
Tetanus, 1063; antitoxin, 215; antitoxin, intraspinous use of, 1075; bilateral phrenicotomy for respiratory spasms of, 1022; germs in felt, presence of, 806; in war, 889; intravenous injections of chloral in treatment of, 572; magnesium sulphate treatment of, 310, 686, 1064, 1102; neonatorum, successful treatment of, 383; problem, 1022; prevention of, in army, 938; serum, 886; serum therapy, 1023, 1063; traumatic, 894; treatment of, 104, 1064, 1101, 1102; treatment of, anaphylaxis in, 1101.
Therapeutics, Bier's substitution, in ophthalmology, 572; calcium, 603; general and experimental, in cancer, 651; measures of standard, 819; physical, 926; mechanical vibration, and exercise, 819; tuberculin, experimental basis of, 945; vaccine, influence of, on blood morphology, 943; *x*-rays in, 477.
Thermotherapy and hydrotheraphy, 819.
Thomson, W. H., vasomotor disorders, 753.
Thorax, complications of, in rickets, 42; funnel, 1099; right cavity of, diaphragmatic hernia into, 655.
Throat, focal infection of, 892.
Thromboangiitis obliterans, and ulcer of toe, 860; an infectious disease, 863; cases of, 860; with Wassermann reaction, 833.
Thrombophlebitis, puerperal, 693.
Thrombosis and embolism, in abdominal and pelvic surgery, 38.
Thymus, and pituitary extracts in treatment of exophthalmic goiter, 75; clinical aspects, 730; deficiency symptoms, 806; extirpation in treatment of goiter, 303; extirpation, results of, 607; enlargement of, employment of skiagraphy in diagnosis of, 665; hypertrophy of, *x*-ray treatment of, 488; obstruction, 739; relation of exophthalmic goiter to, 310.
Thyroid, arseno-ferratose in diseases of, 986; deficiency, 489; deficient function of, see hypothyroidism; excessive function of, see hyperthyroidism; extraction in facial hemiatrophy, 906; operations under local anesthesia, 767; preparations, influence of, on lungs, 643; toxemia, and incipient pulmonary tuberculosis, 179; transplantation, 303.
Thyroiditis, acute, 883; ligneous of Riedel and ligneous phlegmon of Réclus, 564.
Tibia, compression fracture of upper extremity of, 1004; osteoperiostitis of tubercle of, 576.
Tic, pedal, 159.
Tissue, cultures in arthritis deformans, 946; cultures, tropisms in, 676; healthy, improper removal of, 19; living, causing hemostasis, 172.
Titus, E. W., cow's milk, raw and heated, 58.
Tobacco, and alcohol and life expectancy, 773; and war, 698.
Tobie, W. E., a case of volvulus of the jejunoileum with anterior gastroenterostomy, 197.
Toe, ulcer of, and thromboangiitis obliterans, 860; progressive gangrene of, 181.
Tongue, and palate, soreness of, early symptom of pernicious anemia, 349; black, and its causation, 763; cancer of, prognosis in, 855; carcinoma of, 357, 653; carcinoma of, with amyloid disease, 602; chewing, 391; complete removal of, 223, 653; hypernephroma of, 771; lymphatics of, 358.
Tonsil, as habitat of oral endamebas, 936; from surgical viewpoint, 523; infection of, practical points in, 799; pharyngeal, in adult, 61; use and abuse of, 42.
Tonsillectomy, indications and choice of operation, 286; versus tonsillotomy, 1059.
Tonsillitis, follicular, care in treatment of, 379; follicular, with acute gastric fever, 873.
Tooth, caries and internal secretions, 127; incisor, fracture of, with dental cyst, 173.
Torsion spasm, progressive, 885.
Toxemia, of pregnancy, ocular manifestations of, 124; of pregnancy, treatment of, by duodenal enema, 102; thyroid, and incipient pulmonary tuberculosis, 179.
Trachea, and larynx, roentgenography of, 981; perforation of tuberculous lymph node into, 263.
Tracheotomy, for laryngeal diphtheria, deferred death after, 216; new device in, 424.
Transfusion, and splenectomy for pernicious anemia, 860; by the syringe-cannula system without skin-incision, 37; cannula modification of Crile, 511; hemophilia treated by, 861; hemolysis following, 898; in hemorrhagia neonatorum, 891; purpura hemorrragica treated by, 861.
Tribromonaphthal as disinfectant, 816.
Trichinosis, 593; cases of, 282.
Tropeolin as indicator for gastric acidity, 768.
Trophoneurosis, causing progressive gangrene of toes, treated by repeated hypodermoclysis with Ringer's solution, 181.
Tubercle bacillus, and *Bacillus coli*, infection of middle ear with, 585; cultivated from blood, 893; lecithin and, 1099; volatile substances isolated from, 437.
Tuberculin, favorable and unfavorable reactions to, 756; in diffuse erythematous lupus, 274; test, subcutaneous, and von Pirquet test, comparative value of, 179; therapy, experimental basis of, 945; therapy, present imperfections and future improvements, 945; topical employment of, in surgery, 437; used in serous cavities, 945.
Tuberculosis, 210; acquisition of, 437; and erythema nodosum, 728; and Federal government, 1068; and home conditions, 302; and immunity; and National Insurance, 210; and nerve block, 853; and pottery industry, 179; bladder, carbolic installation in, 522; bone, 467; bone and joint, heliotherapy in, 179; bovine and early tuberculosis in childhood, 42; bovine, protectiveness to man, 340; bovine, severe fatal infection of mankind with, 602; cause and prevention of, 210; chronic ocular, 124; complement fixation reaction in, 559; creosote, calcium, and phosphorus therapy in, 908; dry-air baths in treating, 178; experimental, as affected by volatile substances isolated from tubercle bacilli, 437; home hospital experiment, 438; ileocecal, 180; ileocecal, 182; immunity in, 642; in childhood, diagnosis and treatment of, 599; in children, 599; in children and fat absorption, 40; incipient and inactive, and pregnancy, 692; in infancy and childhood, 356; infantile, prevention of, 596; interruption of pregnancy and sterilization in, 771; modern warfare against, 681; municipal house inspection in campaign against, 597; of bladder, treatment of, 992; of conjunctiva, 812; of foot and flat foot, 349; of glands of neck, nonoperative treatment of, 437; of glands, *x*-ray treatment of, 172; of ileum, perforated stenosing ulcer, resection, ileocolostomy, 180; of lymph nodes, 263; of mastoid, 732; of nephrectomy for, 223; of sclera, primary, 455; present situation in, 935; private sanatoria for, 179; problem in rural communities, 630; problems in, 177; prolonged subnormal temperature in, 176; pulmonary, see pulmonary tuberculosis; renal, 92, 980; sanatoria, after-care of patients discharged from, 597; sanatoria in the South, 1068; State policy in management of, 1068; surgical, cholin borate in, 348.
Tumors, anal and rectal, benign, 77; brain, cerebrospinal fluid in, 78; extramedullary, and lumbar puncture, 1062; fibroid, see uterus; internal, radium treatment of, 303; malignant, see cancer; of bladder, 303; of bladder, radium treatment of, 213; of bladder, treated with high-frequency currents, 771; of cecum and colon, 977; origin and growth of, 384; pituitary, 171; radiation treatment of, 303.
Tweddell, F., cause and prevention of pyorrhea alveolaris and furunculosis, 16.
Twilight sleep, 988; in practice, 967; study of 150 cases of, 797.
Typhoid fever, and cholera, inoculation against, 686; "bruit de galop" in, 719; carrier at public dinner, 854; diagnosis of, 671; diet in, 558; due to bacillus carrier, 763; effect of high calory diet on fecal flora in, 444; effects of food on metabolism in, 559; hemiplegia in, 173; hemorrhagic, 261; hypodermic injections of hexamethylentetramine in, 362; in children, 484; in early life, 307; in infants and young children, high caloric diet in, 485; inoculation against, 517; perforation, 386; rational diet for, 579; ulcerative angina in, 259; vaccination against, 929; vaccination against, in British army, 468; war and, 1061.
Typhus, bacilli, excretion of, in carriers, 127; epidemic of, in Van, Turkey, 509.
Tyrrell, J. B., foot troubles as a factor affecting human efficiency, 803.

U

Ulcer, duodenal, see duodenum; gastric, see stomach; of leg, inveterate, 291; of toe and thromboangiitis, obliterans, 860.
Umbilicus, infections of, 715.
Unger, M., a new combined head-mirror and face-protector, 971.
Uremia, and indicanemia, 732; as terminal manifestation, 677; clinical varieties of, 761; uremia, symptoms of, 117.
Ureter, and kidney, *x*-ray determination of variations of, 521; supernumerary, 652.
Urinary tract, calculi of, treatment of, as based on their clinical composition, 692; upper, pyogenic infections of, 521.
Urine, acute retention of, from morphine, 434; analysis of, in childhood, 39; dextrine in, 683; diastase test of, in pancreatic lesions, 29; in kidney ptoses, bacteriological findings in, 693; incontinence of, in women, 815; secretion, in nursling, 1102.
Urobilin, aldehyde reaction for, 1087.
Urology, anesthesia in, 429; gynecology, and general surgery, 872, 905, 906.
Urticaria, pigmentosa, 274; treatment of, 824.
Ussher, C. D., an epidemic of typhus fever in Van, Turkey, 509.
Uterus, adenocarcinoma of, completely removed by exploratory curettage, 987; and breast, cancer of, *x*-ray in, 596; anesthesia of, 263; bladder, and rectum, operation for displacement of, 692; bleeding of, pathological physiology of, 38; cancer of, 934; cancer of, apparently cured by postoperative infection, 693; cancer of, necessity of constantly looking for, 689; cancer of, radical treatment of, 472; cancer of, radium in treatment of, 898; carcinoma of, treated by heat, 471; carcinoma of, specimens of, obtained by Wertheim's operation, 91; carcinomatous, removed by radical abdominal operation, 93; crying of child in, 136; curettage of, sepsis following, 92; displacement of, mechanics involved in, 398; fibroids of, and pregnancy, fibroids of, nonsurgical treatment of, 400; fibroids of, treatment of, 353; fibroids of, extensive resection of uterus for, 691; healed uterovesical fistula with abdominal extirpation of, 982; hemorrhage from, after menopause, 933; hemorrhage from, *x*-ray treatment of, 38; interposition of, end results of, 399; inversion of, following delivery, 135; obstruction of, 442; procidentia of, treatment of, by position, 399; prolapse of, Goffe's operation for, 91; retrodeviation of, 394.

V

Vaccination, eruption complicating, 920; antidysenteric, 391; antityphoid, 516; antityphoid, 929; antityphoid, in British army, 468; compulsory, 427.
Vaccines, cancer, and anticancer globulins as aid in surgical treatment of malignancy, 85; external, use of, 272; in eye diseases, 812; in pertussis, 39, 806; in puerperal infection, 27; in relation to mouth infection, 943; in treatment of wounds, 19; influence of, on blood morphology, 943; preparation of, 944; rational use of, 373.
Vaccinia, organism of, 204.
Vagina, carcinoma of, 195.
Vagitus uterinus, 136.
Vasomotor disorders, 753.
Veins, varicose, and hemorrhoids, in life insurance, 311.
